Jubata; Maned Seal. The neck of the male is covered with a mane of loofe floating hair. It is of a reddifh colour; the young more dufky, in the female more vivid; it is larger than the P. leonina, being about twenty-five feet long, and fometimes weighing 1600lbs. The animals of this fpecies inhabit the Penguin and Seal iflands, near Cape Defire, on the coaft of Patagonia, and are found within the Magellanic ftraits, and on the Falkland iflands, but they have not been difcovered in any other part of the fouthern hemifphere, or in any other place nearer than the fea between Kamtfchatka and America. They live in families diftinct from the Urfine and other feals, though their manners are nearly the fame. The males utter a fnorting found, and occafionally roar like bulls; the voice of the females refembles that of calves, and the young bleat like lambs.

Vitulina; Sea Calf. The head of this fpecies is without ears; the neck is fmooth; the body is brown. There are three other varieties.

(1) *Botnica*, in which the nofe is broader; the claws longer; the colour more obfcure.

(2) *Sibirica;* colour filvery. It inhabits the lakes of Baikal and Oron.

(3) *Cafpica;* the colour of this is various.

Whifkers undulate; the eyes have a nictitant membrane; the cryftalline humour is globular; the tongue is bifid. The legs are fo very fhort as to be fcarcely perceptible; and the hinder ones are fo placed as to be only of ufe to the animal in fwimming, or but very little to affift it in walking; being fituated at the extremity of the body. When thefe animals collect together in great numbers on the fhore, they diffufe a very ftrong and difagreeable fmell, a fact that is noticed by Homer, who reprefents Menelaus relating his adventure on the ifle of Pharos, where he was conftrained to lie for a time among a flock of feals, difguifed in the fkin of one of thefe animals. The ftructure of the feal is fo fingular, that, as Buffon obferves, it was a kind of model on which poets formed their tritons, firens, and fea-gods, with a human head, the body of a quadruped, and the tail of a fifh. The feal is poffeffed of a confiderable degree of intelligence, and may be tamed, fo as to become perfectly familiar with thofe to whofe care it is committed; and even to exhibit tricks and gefticulations. The feal is fuppofed to be a very long lived animal. Like other quadrupeds, they have various inflexions of the voice, according to the paffions with which they are infpired. They are faid, however, to differ from them in this, that they delight in thunder ftorms, and at fuch periods to fit on rocks and contemplate with feeming delight the convulfions of the elements.

Monachus; Hooded Seal. Head without ears; there are four fore-teeth in each jaw; the fore feet are undivided; the hind feet without nails. This fpecies has obtained the name of Monachus, or cowled feal, from the loofenefs or width of the fkin behind the neck, which, when the animal is placed on its back, folds like a monk's cowl. It inhabits the Mediterranean, about the coaft of Dalmatia, growing to the length of more than eight feet. The head is fmall, the neck longer than that of the common feal; the orifices of the ears not larger than a pea; the hair is fhort and rude; the colour is dufky, fpotted with afh-colour; the toes on the fore feet have nails; but the hind feet refemble fins, and have no nails. This fpecies is fully and accurately defcribed in the 4th vol. of the Berlin Tranfactions.

Grenlandica; Harp Seal. Head fmooth, without ears; body grey; a lunulate black mark on the fides. It inhabits Greenland and Newfoundland; it is highly efteemed on account of the excellence of its fkin, and the quantity of oil which it yields.

Hispida; Rough Seal. Head fmooth without; body pale brown, rough, with briftly hairs. It inhabits Greenland and Labrador, feeds on fhrimps and fmall fifh; it often fleeps on the furface of the water; the flefh is red and naufeous; it is only about four feet long. A variety is much larger, and weighs perhaps 500lbs.

Cristata; Crefted Seal. Head on the fore part crefted; body grey. This fpecies is alfo diftinguifhed by a ftrong folded fkin on the forehead, which it can at pleafure draw over the eyes and nofe, to defend them againft the ftones and fands raifed and fcattered in ftormy weather. Its hair is white, with a thick coat of black woolly hair beneath, which makes the animal appear of a fine grey. It is found only on the fouthern parts of Greenland and Newfoundland; and in the latter it is called the hooded feal.

* Barbata, or Great Seal. Head fmooth, without ears; the body is blackifh. This is fimilar to the common feal, but grows to about the length of twelve feet, it having been fhot in the north of Scotland of that fize. Even when fo young as to be without teeth it is upwards of feven feet long, whereas the common feal is at its full growth when it has arrived at the length of fix feet. It is found in the northern feas. The fkin, which is thick and very ftrong, is ufed by the Greenlanders for thongs for their feal fifhery. The young ones, when firft brought forth, are quite white.

Pusilla; Little Seal. Head fmooth, with the appearance of ears. It inhabits the Mediterranean fea, Chili, and Juan Fernandez, and is about twenty-eight inches long.

Chilensis. Snout and ears longifh, toes five on each foot. It inhabits about the coaft of Chili.

Mutica; Long-necked Seal. Body flender, without claws on the fore feet.

Australis. Ears fhort and pointed; the body is cinereous; hairs tipt with dirty-white; nofe fet with ftrong, black briftles; the upper fore-teeth are tranfverfely furrowed; the lower longitudinally; tufks with a fmaller fecondary tooth on each fide; grinders conic, with a fmall procefs on one fide near the bafe.

Testudo; Tortoife Seal. Head refembling a tortoife; neck flender. It is faid to inhabit many European fhores; the fpecies is, however, but little known.

Fasciata; Ribbon Seal. Body blackifh; neck, fide, and haunches with yellow ftripes refembling harnefs. It inhabits the Kurile iflands, and is covered with fhort, fine, gloffy, black hair.

Laniger: Leporine Seal. It has four fore-teeth in each jaw; the upper lip is thick, with long thick whifkers; the fur is foft and uneven; the feet have nails, and its length is about fix feet and a half. It inhabits the White fea, Iceland, and the Frozen ocean.

Punctata; Speckled Seal. Body, head, and limbs fpeckled. It inhabits the feas of Kamtfchatka, and the Kurile iflands.

Maculata; Spotted Seal. Body fpotted with brown. It inhabits the Kurile feas, and is very fcarce.

Nigra; Black Seal. Hind legs peculiarly formed. It is found on the coafts of the Kurile feas; but the ftructure of its legs has not been accurately afcertained.

Dr. Parfons derives the generic name *phoca*, from φωκη, or, according to Dr. Charleton, from βωκη, fignifying a noife or kind of grunting made by thefe animals. He alfo reduces to this genus the *manati*, the *foil* or *feal*, and the *walrus* or morfe. Phil. Tranf. vol. xlvii. 109, &c.

PHOCÆA, in *Ancient Geography*, a town of Afia Minor, belonging to the Ionians, fituated on the fouthern coaft of the gulf of Cumæ, N. of the mouth of the Hermus. It had two ports. Its inhabitants had a very extenfive commerce along the Mediterranean; and they founded feveral colonies, and among others that of Marfeilles.

PHOCÆNA, or Porpesse. See Delphinus.

PHOCAIS, in *Ancient Geography*, a territory of Afia, towards the mouth of the Caicus, on the coaft of Mitylene, according to Thucydides.

PHOCARIA, an ifland of the Ægean fea, upon the coaft of Attica. Pliny.

PHOCARUM Insula, an ifland on the coaft of Arabia. Strabo.

PHOCAS, in *Biography*, Roman emperor of the Eaft, was a centurion in the army on the Danube at the time of the revolt from the emperor Maurice, A. D. 602, nor is it at all known how he came to be elected emperor; but probably from his becoming a leader in fome fedition. On the intelligence of this revolt, the people of Conftantinople broke out in an infurrection, and Maurice was obliged to retire into Afia. Phocas foon after entered the capital, and with his wife was crowned by the patriarch. At the public games which he exhibited on the occafion, a tumult arofe, in which he was reminded with threats that Maurice was ftill alive. The death of that unfortunate emperor, with that of his five fons, foon followed. The reign of the infamous Phocas was full of bloodfhed and cruelty, fo that he has been juftly ranked among the moft deteftable of tyrants. At length he became an object of terror to his own fon-in law, Prifcus, who entered into a correfpondence with Heraclius, exarch of Africa, for the purpofe of effecting a revolution. Phocas was, by the arts of Prifcus, kept ignorant of his danger till it was too late for effectual oppofition. Deferted by his guards and domeftics, he was feized in his palace, ftripped of his imperial robes, and carried to the galley of Heraclius, who had been proclaimed emperor. After fuffering a variety of infults and tortures, his head was cut off and his body committed to the flames, A. D. 610, in the eighth year of his reign. Univer. Hift. Gibbon.

PHOCEAS, in *Ancient Geography*, a town of Sicily, in the territory of Leontium. Thucydides.

PHOCENSES, a people of Greece, between Ætolia and the ifthmus of Corinth.—Alfo, a people of Phocæa, and alfo of Italy, in Etruria. Strabo.

PHOCION, in *Biography*, an Athenian commander, one of the moft virtuous characters of antiquity, was of humble defcent, but received a liberal education, and imbibed under Plato, and other philofophers, thofe elevated principles of conduct which governed his whole life. As he wifhed to ferve his country equally in council and the field, he cultivated the talents adapted to both. He firft ferved under Chabrias, a diftinguifhed commander, but of an impetuous temper. Phocion gained his efteem and moderated his violence. He contributed to the naval victory near Naxos, in the year 377 B. C.; and being afterwards fent in a fingle veffel among the iflands to demand their contributions, he conducted himfelf with fo much prudence, that he brought back with him all the fhips and money at which they were affeffed. In the war with Philip of Macedon he obtained a complete victory, and on this occafion he gave a fignal proof both of his wifdom and humanity. Before the battle he freely fuffered thofe to depart who had no inclination to fight, left their cowardice in action fhould difconcert the reft; and after the victory he releafed his prifoners, knowing the danger they would incur if brought to Athens, from the violence of the populace. Phocion, though an able general, was the habitual friend of peace. He was too well apprized of the unftable character of the Athenian democracy, and the talents and refources of Philip, not to be convinced that a protracted war muft be fatal to his country; hence he was the conftant oppofer of thofe orators, who never ceafed to urge the people to hoftilities, and to difcountenance all propofals for accommodation. The pure patriotifm and integrity of Phocion were founded on their only folid bafis, contentment with a little. Amidft the higheft honours, his mode of living was as fimple and frugal as that of any common citizen. He poffeffed a little farm, and was not afhamed to perform domeftic offices with his own hands. He had a wife who was a worthy partner of his virtues, and placed her glory in his reputation. An Ionian lady once making a difplay before her of all her jewels and other finery, "My ornament," faid the matron, "is my good man Phocion, who is now called for the twentieth time to the command of the Athenian armies." When the people of Megara were privately meditating an union with the Athenians, Phocion zealoufly promoted the meafure; and, affembling a body of volunteers, marched thither, and was joyfully received; and having rebuilt its walls, left it in a ftate of fecurity, as a valuable acceffion to the ftrength of Athens. When Philip entered Phocis, with the intention of invading Attica, Phocion not confiding in the alliance with the Bœotians meditated by Demofthenes, was defirous of an accommodation; but he was over-ruled, and the fatal battle of Cheronea proved the juftnefs of his apprehenfions. The death of Philip was celebrated with great rejoicings at Athens by Demofthenes and his party, but Phocion difcouraged fuch indecorous triumph, and

and bid them remember that the victors at Cheronea were diminished only by one man. In the same spirit of avoiding new hazards he disapproved of the contemptuous speeches relative to young Alexander, and the attempts to form a confederacy against the Macedonian power. At length, after a long life spent for the advantage of his country, he was for an error in judgment accused of treason. The populace shewed the greatest exasperation against him, and would scarcely suffer him to speak. At length, obtaining an interval from clamour, he cried, "Athenians, I confess the crime charged against me, and submit to the sentence of the law; but what have these innocent men (pointing to some involved in the same punishment) done to deserve death." The cry of the people was, "They are your friends, and that is enough." The decree was then passed adjudging them all to die, and some even proposed a clause for putting Phocion to the torture. The aged patriot, unmoved amidst the lamentations of his friends and fellow sufferers, was led away, even his enemies admiring the serenity of his demeanour. The popular indignation against him denied his body a funeral in his own country, and it was carried by a slave and burnt in the territory of Megara. A matron with her maid attended on the obsequies, and raising an humble monument on the spot, collected his ashes, and deposited them under her own hearth, praying the houshold gods to protect them till they should be restored to the sepulchre of his ancestors, when the Athenians should have recovered their senses. This event took place; and his countrymen repenting the wrong they had done him, brought home his ashes at the public expence, erected a brass statue to his memory, and punished with death his accusers. This event occurred in the year 318 B. C. Plutarch. Univer. Hist.

PHOCIS, the *Phocide*, in *Ancient Geography*, a country of Græcia propria; which extended from the N.W. or the Doride to the S.E., where it touched Bœotia, and to the W. bordering on the Ozole Locrians, to the S.W. as far as the gulf of Corinth, and to the N.E. where were the Opontian Locrians and the Epicnemidian Locrians. Although it was watered by many streams, it formed from the N.W. to the S.E. an extensive valley, in the middle of which flowed the Cephissus. Its other principal rivers were the Pindus and the Cachalis. The chief mountain was Parnassus, where were Delphi and the Castalian fountain. The most considerable places were Delphi (Castri), Crissa, Anticyra (Aspro-Spiria), and Elatia (Turco-Chono), the most considerable of the towns in the Phocide. The Phocæans, according to Pausanias, derived their name from Phocus of Corinth, or from Phocus the son of Æacus, who came to this country with the Æginetæ, who made themselves masters of it, and gave it the name of the Phocide. Pausanias mentions several military expeditions of the Phocæans, *viz.* their concurrence in the siege of Troy; their war against the Thessalians, in which they gained great honour; and their participation in what was called the sacred war, in which Philip of Macedon took a part. The Phocæans were ultimately excluded from the council of the Amphictyons.

PHOCLIS, a town of Arachosia, between Axola and Aricara. Ptolemy.

PHOCRA, a mountain of Africa, in Mauritania Tingitana, which, according to Ptolemy, extended from the lesser Atlas to the promontory Bysadium.

PHOCUSSA, or PHACUSSA, an island of the Ægean sea, and one of the Sporades, according to Pliny and Steph. Byz.

PHŒBEUM, a place of the Peloponnesus, in Laconia, in the environs of Sparta. Livy.

PHŒBI PROMONTORIUM, a promontory of Africa, in the Iberian sea, between Jagath and Alyba-Colauna. Ptolemy.

PHŒBIA, a town of Greece, in the Peloponnesus, which, according to Pausanias, belonged to the Sicyonians.

PHŒBUS, in *Mythology*, a name given to Apollo.

PHŒMIUS (*Phamauh*), in *Ancient Geography*, a river of Africa, in the eastern part of Mauritania Cæsariensis.

PHŒNICA, or PHŒNICE, a town of Epirus, in Chaonia, according to Ptolemy, Livy, and Polybius.

PHŒNICA (*Fenck*), a town of Asia, at some distance N.N.W. from Tigranocerta; S. of the lake Thospitis, and besieged and taken by Sapor, king of Persia, as Ammianus Marcellinus reports.

PHŒNICE, PHŒNICIA, a country of Asia, commonly named by the Jews *Canaan*, though some part of it, at least, was known to them by the name of Syrophœnice. Phœnice was sometimes extended to all the maritime countries of Syria and Judæa, and Canaan to the Philistines, and even to the Amalekites. On the contrary, these two names, and the rest, were most generally swallowed up by those of Palestine and Syria; or rather Phœnice, Palestine, and Syria, were promiscuously used for each other, and particularly the two former. Stephanus Byzantinus says, that Phenice and Palestine are the same. Syria, in its largest extent, sometimes comprehended Phœnice and Cœlesyria. The fact is, that the whole coast of the Mediterranean sea from Libanus to Rhincorura, or to mount Casius, in the vicinity of Egypt, before the departure of the Israelites from this last country, was inhabited by people of different origin, *viz.* the Canaanites, afterwards called Phœnicians, descended from Canaan; and the Philistines, sprung from Mizraim. These people lost part of their possessions by the conquest of Joshua, who put the Israelites in possession of the middle part of this coast, from Jamnia to mount Carmel. But when the Israelites were carried into captivity by Salmanasar, 721 years B. C., the portion of the country which they had occupied returned to its first masters, who reunited it to their ancient dominion. From this time the Phœnicians and Philistines were so united, that they were considered as the same people, and the whole coast was known by the name of Phœnicia. Strabo (l. xvi.) makes Phœnicia to commence, towards the N., at the town of Orthosia to the S.W. of Aradus; but Ptolemy extends it a little farther to the N., and removes it to the river Eleutherus, which falls into the sea, N.E. of Aradus, and at a small distance from it. The greatest part of the coast of Phœnicia was bounded to the E. by the mountains of Libanus, which are covered with snow during the whole winter. This snow has such a refrigerating effect on the air, that the country towards the N. is cold; but to the N. and S. of these mountains, the air is very temperate.

The proper Phœnice, as far as we can learn from the ancient geographers, lay between the 34th and 36th degrees of north latitude: bounded by Syria on the N. and the E., by Judea on the S., and by the Mediterranean on the W. Ptolemy, as we have already said, reckons the river Eleutherus the boundary of Phœnice to the N., but Pliny, Mela, and Stephanus, place it in the island of Aradus, lying N. of that river. On the coast of Phœnice, and S. of the river Eleutherus, stood the following towns; Simyra, Orthosia, Tripolis, Botrys, Byblus, Palæbyblus, Berytus, Sidon, Sarepta, Tyrus, Palætyrus. Sidon may be properly called the metropolis of Phœnice. For an account of the principal towns of Phœnice, see their respective names. In the midland Phœnice Ptolemy reckons the following towns, *viz.* Arca, Palæbyblus, Gabala, and Cæsarea farea Paniæ. This province was confiderably extended in the times of Chriftianity; when being confidered as a province of Syria, it included not only Damafcus, but Palmyra alfo.

The foil of this country is good, and produces many articles both of food and clothing; the air is falubrious, and the climate agreeable. The fea on this coaft formerly produced a quantity of fuch fifh as yielded great profit to Tyre in particular: fuch was the murex, with which was dyed the choiceft purple; and on the fhore was a fand with which the firft and beft glafs was made, as a ftaple manufacture of this country. Although this country has been long defolate, it exhibits fome remains of its ancient fplendour, more efpecially at Tyre, Sidon, Byblos, &c. which fee refpectively.

The Phœnicians were, without doubt, defcendants of the Canaanites: though, in procefs of time, their blood was intermixed with that of foreigners, from the natural courfe of their commerce with other countries. Many ftrange families muft have fettled among them, who could confequently have no claim to this remote origin, how much foever they have been called Phœnicians, and reckoned of the fame defcent with the ancient proprietors. Bochart indeed infinuates (vid. Phaleg. lib. iv. cap. 34.) that the Canaanites were afhamed of their name, on account of the malediction denounced on their progenitor, and that they were terrified by the wars, which had been with equal vigour and fuccefs waged againft them by the Ifraelites, becaufe they were Canaanites; and that, therefore, to avoid the ignominy of the one and the danger of the other, they abjured their old name and changed it for Phœnicians, Syrians, Syrophœnicians, and Affyrians. Heidegger alfo conjectures, that they were afhamed of their anceftor Canaan. As to the etymology of their name, learned writers have fuggefted a variety of conjectures. The mythological hiftorians have traced it to a pretended Phœnix, fon of Agenor, or to a Phœnix, faid to be the fon of Neptune and Libya. Others have derived it from Φοινιξ, or the palm-tree, with which Phœnice is faid to have abounded. Scaliger pretends that the name of Phœnician was formed from *Pinkkas*, or *Pinnhas*, meaning a perfon who infpires confidence, which as he fuppofes was given to Canaan by the Sidonians. The learned Bochart feems to have approached nearer to truth in his conjecture. According to him, thefe people had, in ancient times, been called the children of Anak, or "Beni-Anak:" the *beth* being foftened, Beni-Anak was changed into "Phenak," in the plural "Phenakim," from which the Greeks formed "Phœnices." We learn from fcripture, that the fpies fent by Mofes found in Hebron and its environs a people called "Anakim," or "Enakim:" and that thefe Canaanites were diftinguifhed by their ftature and ftrength: of courfe, the other Canaanites who claimed the honour of defcent from them were alfo denominated "Anakims."

M. l'Abbé Mignot, in his elaborate difcuffion of this fubject, (Mem. Acad. Belles Lettres, tom. xxxiv. &c.) thinks that it is not neceffary to recur to the word "Beni;" becaufe the Egyptians always prefix the article *phe* to words, fo that inftead of "Enakim," they would read "Penakim," or "Phonacim:" and the Greeks becoming acquainted in their firft maritime expeditions on the coaft of the country with this word, formed from it Φοινικες, and the Latins "Phœnices."

It has been prefumed by this ingenious writer, who has taken great pains in tracing the origin of the Phœnicians, that a new colony of Canaanites arrived in this country, which drove the ancient inhabitants towards the N., and in proof of this opinion he refers to Gen. xii. and xiii. Thefe new Canaanites he fuppofes to have been the Orientals whom authors have diftinguifhed by the appellation of "Egyptian Shepherds," and who, after having been driven from the country which they had once poffeffed, returned again to Paleftine. Accordingly he fuppofes thefe "Shepherds," of whom we fhall have occafion to fpeak in another article, were the progenitors of the Phœnicians. The kings of the Thebaid, and other princes of Egypt, formed a league againft them, and carried on a war, which was long and cruel; till at laft the king Mufphar Muthofis obliged them to withdraw into a canton, which contained 10,000 arouræ or Egyptian acres. The Shepherds fortified this place and encompaffed it with walls for the fecurity of their poffeffions. Thummofis or Thetmofis, at the head of 480,000 men, befieged this place; but defpairing of fuccefs, he treated with the befieged, and granted them permiffion to retire, with their whole property, to any place they might choofe, without being purfued or difquieted in their march. The Shepherds accordingly quitted Egypt, and purfuing their route through the defert, arrived in Syria, and fettled in the country which was afterwards called Judea. This departure of the Shepherds from Egypt is faid to have taken place before the arrival of Jofeph in that country, *i. e.* in the year 1728 B.C. This fragment of ancient hiftory throws great light, according to the abbé Mignot, on the Egyptian allegories. The fynchronifm of the arrival of the Phœnicians in Egypt with the reign of Menes, leads us to imagine, that the whole fable of the war of Typhon againft Ofiris is an allegory, under which is veiled the hiftory of the war of the Phœnicians or Canaanites againft the Egyptians. Typhon was the brother of Ofiris; and he correfponds to the Canaanites, who were defcended from Canaan, the brother of Mizraim, and who might be called the brethren of the Egyptians, according to Eaftern ufage: but although brethren they were not born in Egypt, which the fable fufficiently indicates, by the different colour which it gives to Typhon, who was red. The Egyptians, compared with the Canaanites, were almoft black. According to the fable, the war between Typhon and Ofiris was long, and terminated by the retreat of Typhon from Egypt, thus characterifing the expulfion of the Shepherds. Typhon retired to Abaris, which was called the city of Typhon; but he was obliged to leave it and to abandon the whole country: and as he never returned, he is thought to have been drowned in the overflow of the waters of the Sirbonite lake: but his death is fuppofed to have been allegorical; for, according to Plutarch, (De If. and Ofir.) he had two fons, Judæus and Jeralymus; the meaning of which is, that he entered into Syria, and fettled in the country of Canaan, fince occupied by the Jews, and in which was the city of Jerufalem. According to the abbé Mignot, the commencement of the reign of Salatis, the firft Shepherd king, may be fixed to the year 2078 B.C., and their departure to the year 1793, before the fame era. The Phœnician Shepherds re-entered the country of Canaan, from which, about three centuries before, they had departed for Egypt, and fettled towards the fouth; and, according to Juftin (lib. xviii. c. 3.) they eftablifhed themfelves in the vicinity of the lake of Affyria, *i. e.* the lake Afphaltites; but multiplying there they were under the neceffity of extending their borders, and taking poffeffion of the territory of the fea-coaft, which the firft inhabitants of the country had left vacant; and fome of them fettled in the neighbourhood of the Jordan. Their arrival in Paleftine was the caufe which induced fome of the ancient

inhabitants

inhabitants to remove towards the north. There they multiplied themſelves to ſuch a degree, that the country, which in the time of Jacob was deſtitute of inhabitants to cultivate the ſoil, was peopled with a race which terrified the ſpies of Moſes by the magnitude of their cities, and by the number and power of thoſe who inhabited them. The Philiſtines alſo are ſaid to have come from Egypt; they were eſtabliſhed to the ſouth of the Canaanites, having, in former times, inhabited Peluſium and its territory. The Caphtorim were alſo of the ſame race; and theſe people, together with the Canaanites, conſtituted the nation, which, in proceſs of time, bore the name of Phœnicians. (See PHILISTINES.) Another French author, *viz.* M. de la Nauze, maintains (Mem. de Let. t. xxxiv. M. p. 175.) that the Phœnicians, who were alſo called Erythræans, were deſcended from Edom or Eſau, and that the Jews conſidered them as brethren. He ſays alſo, that Eſau was the ſame with king Erythras, both names ſignifying red; and that he was one of the firſt kings of this nation. But the reply of the abbé Mignot comprehends the following propoſitions, *viz.* 1. That the principal towns of the country to which the Greeks gave the name of Phœnicia, had for their founders and firſt inhabitants, the children and deſcendants of Canaan. 2. That the inhabitants of Tyre and Sidon, whilſt they were called Phœnicians by the Greeks, were named Canaanites in the original text of ſcripture. 3. That the tranſlators of the bible, which, in the time of Ptolemy Philadelphus, had rendered the Pentateuch into Greek, were perſuaded that the Phœnicians were Canaanites, as they often expreſs the Hebrew word "Kenani" by thoſe of Φοινικες and Φοινισσας, or Phœnicians. 4. That the Phœnicians gave themſelves the name of Canaanites. 5. That ſome profane authors, ſuch as Sanchoniathon and Philo of Biblos, his tranſlator, aſſure us, that Chna, or Canaan, was the father of the Phœnicians: and others have called Phœnicia the land of Canaan.

The Phœnicians were governed by kings, and their territory, ſmall and narrow as it was, included ſeveral kingdoms, *viz.* thoſe of Sidon, Tyre, Aradus, Berytus, and Byblos or Byblus. In this reſpect they imitated and adhered to the primitive government of their forefathers, who, like the other Canaanites, were ſubject to many petty princes, to whom they allowed the ſovereign dignity, reſerving to themſelves the natural rights and liberties of mankind.

As to their *religion*, the Phœnicians, being originally Canaanites, were at firſt worſhippers of the true God. In the time of Abraham the worſhip of the Canaanites was not different from his own. But afterwards they combined with the worſhip of the ſupreme Sovereign, whom they acknowledged to be the firſt cauſe of all things, that of gods, called by the ancients natural and immortal, that is, the ſun, moon, ſtars, and elements. Thus commenced the idolatry of the Phœnicians. They proceeded to reverence as gods thoſe who had rendered any important ſervice to mankind; they decreed to them divine honours; they appropriated temples to their worſhip; they adorned columns, on which their names were inſcribed, and eſtabliſhed ſolemn feaſts in honour of them: and moreover, they gave to theſe new deities the names of the elements, and of thoſe objects to which they had been accuſtomed to attribute divinity. The firſt mortal to whom the Phœnicians paid reverence was *Chryſor*, who had invented the method of founding metals, and applying them to the conſtruction of inſtruments for facilitating agriculture and fiſhing; who had firſt ventured himſelf on the ſea, and who had furniſhed them with the principles of divination. The worſhip of this pretended divinity was eſtabliſhed wherever they had colonies; and a ſimilarity has been obſerved between the Chryſor of the Phœnicians and the *Phta* or Vulcan of the Egyptians. With this deity they aſſociated another called *Agroneros* or *Agrotes*, in honour of whom they erected a ſtatue and a temple, and whom they held in very high eſtimation, as having invented, or at leaſt perfected, the art of tillage.

The other gods of the Phœnicians, named by Sanchoniathon, were *Elioun*, called the ὑψιστος, or moſt high, and his wife *Berouth*, and his deſcendants, who were regarded as the founders of the Phœnician nation. Elioun and Berouth had four ſons, Iſus, called alſo *Chronos*, *Bethylus*, *Dagon*, and *Atlas*. The wife of Chronos was *Aſtarte*, ſuppoſed to be the ſame divinity with Derceto or Atergates, worſhipped at Aſcalon. Cronos had ſeven daughters, called Artemides and Titanides, and two male children, Pothus or Cupidas, and Eros or Love. Cronos had another wife, called *Rhea*, and a third called *Dioné*. To theſe chief deities they joined marine divinities, ſuch as Nereus, the father of Pontus, from whom ſprung Poſeidon or Neptune. The *Cabiri*, called alſo Dioſcuri, Corybantes, and Samothraces, received divine honours. Sanchoniathon mentions another prince contemporary with Cronos, called *Adad* or *Ædad.* To theſe gods we may join *Adonis*, a Phœnician prince, who had reigned over Libanus, and the *dii pataici*, or tutelary gods of veſſels. The Phœnicians had alſo *Beelſamen*, ſignifying lord of honour, and denoting the ſun; *Baal-Berith*, or the Cronos worſhipped at Berytus, and ſeveral others of the name of *Baal*; *Apollo*, *Melicarthus*, *Melcartus* or *Hercules*. There is reaſon to believe, that the Phœnician idolatry and ſuperſtition were not altogether their own; and that their ſubjection to the Aſſyrians, Babylonians, Perſians, and Greeks, made great alterations in the whole ſyſtem of their religion. How far they retained, or loſt, a due ſenſe and notion of the true God in this their multifarious idolatry, it is not eaſy to determine. It is reported of the Egyptians, that, amidſt their endleſs polytheiſm, they ſtill acknowledged one ſupreme God; and ſince the religion of the old Phœnicians was in ſubſtance ſcarcely different from that of the Egyptians, it is very probable that their theory and doctrine agreed together as well as their practice and traditions. *Baal* had his prophets and prieſts in great number. We read of 450 of them, fed at Jezebel's table only. It was their cuſtom to offer burnt-offerings and ſacrifices to this god, and to dance about the altar with violent geſticulations; thus working themſelves up into a kind of phrenſy, and then cutting their bodies with knives and lances, and pretending to propheſy, or rather ſeeming, as if poſſeſſed by ſome inviſible power. This extravagance, in their early days, was accompanied with the barbarous cuſtom of ſacrificing perſons that were moſt dear to them to appeaſe their falſe gods, when they laboured under any public calamities. This inhuman practice is not only charged upon them by the teſtimony of others, but acknowledged by themſelves; and they had it in common with the Egyptians. But it was diſcontinued here, as well as in Egypt, at an early period. (See ADONIS, ASTARTE, BAAL, and HERCULES.) Among other acts of worſhip performed by the Phœnicians, one of the moſt univerſal was that of ſaluting the ſtatues of their gods, or kiſſing the hand in ſaluting them. The prayers which they addreſſed to their gods were preceded by luſtrations, by waſhing themſelves, and changing their garments. They alſo had ſongs, which they chanted to the ſound of inſtruments. The Phœnicians alſo practiſed various kinds of divinations and enchantments. Herodotus ſuppoſes theſe people to have practiſed circumciſion: but Joſephus aſſerts, that

that none of the nations included under the vague name of Paleftine and Syria, ufed that rite, except the Jews: that if the Phœnicians anciently had that cuftom, they afterward neglected it, and at length wholly laid it afide. They abftained from the flefh of fwine.

Language and Writing.—Whatever was the origin of the Phœnician language, it is certain that it had no affinity to the other oriental tongues that were ufed in Arabia, Syria, &c. Their language was a dialect of the Hebrew, the fame with that of the ancient Canaanites, and their letters, or characters, were the fame or very like to thofe of the Samaritans. Their alphabet confifted of the fame number of letters with the Hebrew alphabet ; the forms of their letters were larger ; but they were more conformable to thofe of the more ancient Greek infcriptions. The Phœnician character varied in its figure according to the different cantons in which it was ufed. The character of Palmyra more nearly refembled the Hebrew ; that of Carthage or the Panei, and that of Sicily or Spain, had a common origin, and bore affinity to that of the Phœnicians. The character, which was common to the Phœnicians, Hebrews, Arabs, &c. was the origin of that of all the nations which lay to the W. of Afia ; it paffed into Africa by means of the Carthaginians; it was in ufe in Sicily and Spain before the Romans conquered thofe countries ; Cadmus brought it among the Greeks ; it was adopted by the Etrufcans ; and at length received among all the nations of Europe. Towards the E., it had been for a long time in ufe in Perfia, and it was not improbably the origin, directly or indirectly, of all writing. The Phœnicians, like the Hebrews, Arabs, &c. wrote from right to left ; nor had they any vowels in their alphabet, which proves the antiquity of their language, and as fome have alleged, that it was the inevitable confequence of hieroglyphical writing.

Learning and Science.—The Sidonians, under which appellation we may comprehend the Phœnicians in general, were of a peculiarly happy genius : arithmetic and aftronomy are fuppofed to have taken their rife among them, or were brought by them to great perfection ; from them thefe excellent fciences fpread into Greece, together with their letters. They were addicted from the beginning to philofophical exercifes of the mind ; infomuch, that a Sidonian, named Mofchus, taught the doctrine of atoms before the Trojan war ; and Abomenus of Tyre is faid to have puzzled Solomon by the fubtlety of his queftions. Phœnice continued to be one of the feats of learning, and both Tyre and Sidon produced their philofophers in later ages ; fuch were Boethius and Diodatus of Sidon, Antipater of Tyre, and Apollonius of the fame place, who gave an account of the writings and difciples of Zeno.

Manufactures and Arts.—The glafs of Sidon, the purple of Tyre, and the exceeding fine linen they wove, were the product of their own country, and of their own invention ; and for their extraordinary fkill in working metals, in hewing timber and ftone, and in a word, for their perfect knowledge of what was folid, great, and ornamental in architecture, the reader need only be reminded of the large fhare they had in erecting and decorating the temple at Jerufalem under their king Hiram. Their fame for tafte, defign, and ingenious invention was fuch, that whatever was elegant, great, or pleafing, in apparel, veffels, or toys, was diftinguifhed, by way of excellence, with the epithet of "Sidonian."

Commerce and Navigation.—As merchants they may be faid to have engroffed all the commerce of the weftern world ; and as navigators, they were the boldeft, the moft experienced, and greateft difcoverers, of ancient times : indeed they had, for many ages, no rivals. In planting colonies they exerted themfelves fo much, that, confidering their habitation was little more than the flip of ground that lay between mount Libanus and the fea, it is furprifing how they could furnifh fuch fupplies of people, and not wholly depopulate their native country. Their vicinity to Syria, which had a very confiderable and regular trade with the more eaftern regions, induced them to traffic in foreign commodities ; for here they found productions of the natural growth of that foil, and many choice and ufeful commodities brought from the Eaft, which their own fmall country could not fupply : and having probably been fhewn the way by the Syrians, who might have navigated the Mediterranean, they turned their whole attention to trade and navigation, and by an uncommon degree of application, foon eclipfed their mafters in that art. The Phœnicians affected no empire but that of the fea, and feemed to aim at nothing but an unmolefted enjoyment of their trade. This they extended to all the known parts to which they could reach ; to the Britifh ifles, commonly underftood by the Caffiterides ; to Spain, and other places in the ocean, both within and without the ftraits of Gibraltar ; and, in general, to all the parts of the Mediterranean, the Black fea, and the lake Mæotis. In all thefe parts they had fettlements and correfpondents ; and thus they exercifed the great branches included under the term trade, *viz.* importation, exportation, and tranfportation, in full latitude. Befides this maritime commerce, they had an inland trade in Syria, Mefopotamia, Affyria, Babylonia, Perfia, Arabia, and even India, which was of no lefs extent, and which may ferve to give us an idea of the wealth of thefe people, and how defervedly their merchants are mentioned in fcripture as equal to princes. (If. xxiii. 8.) Their country, though fmall, was the great ftorehoufe that contained every thing which could adminifter to the neceffities or luxuries of mankind, which they diftributed to others as they judged would be beft for their own intereft. Their own commodities were, as we have obferved already, the purple of Tyre, the glafs of Sidon, and the exceeding fine linen made in their own country ; thefe and other curious pieces of art, in metals and wood, feem to have been the chief, and almoft only commodities of Phœnice itfelf. Their territory was fo fmall, as not to afford any export of their own growth ; and, indeed, it is more likely that they wanted, than abounded with, the fruits of the earth. Their commerce and navigation derived peculiar advantage from their fhipping, and they had excellent means for providing themfelves with fhips. Their larger embarkations were of two forts, round fhips, or gauli, and long fhips, gallies, or triremes. When they drew up in line of battle, the gauli were difpofed at a fmall diftance from each other in the wings, or in the van and rear ; and their triremes were contracted together in the centre. In order to difcourage other nations from engaging in commerce, they practifed piracy, or pretended to be at war with fuch as they met when they thought themfelves ftrongeft. This was a natural ftroke of policy in people who grafped at the whole commerce of the then known world. At Tyre was the famous fifhery already mentioned, which contributed fo much to enrich that city. In connection with the navigation of the Phœnicians, we might mention their voyages in the fervice of Solomon ; and the long voyage which fome of them are faid to have undertaken in the fervice of Necho, king of Egypt, round Africa, failing out of the Red fea, and returning by the way of the ftrait's mouth, in which they employed three years.

Hiftorical Revolutions.—Phœnicia, as we have already obferved, was divided into feveral fmall kingdoms, of which fome were confined within the narrow bounds of one city, and

and its territory. Of all the kings of Phœnicia, thofe of Sidon, Tyre, and Arad, feem to have been the moft powerful and wealthy, and they certainly make the moft confpicuous figure in hiftory; but their fucceffors, and the years of their refpective reigns, are involved in obfcurity and uncertainty, and interrupted by fo many chafms, that it is not poffible to give a regular detail of their tranfactions. For fuch an account as authentic hiftory furnifhes, we refer to the refpective articles, *Sidon*, *Tyre*, and *Arad*.

After a variety of viciffitudes, Phœnicia fell under the power of the kings of Babylon. Nabopolaffar, whofe reign commenced in the year 626 B.C., became mafter both of Paleftine and of Egypt. Tyre, after a refiftance of 30 years, was taken in the year 573 B.C. But with the death of Baal, the title of king became extinct; and Phœnicia was for a confiderable time governed by judges. Geroftratus was the laft of thefe magiftrates; and when he died in the year 554 B.C., the Tyrians fent to Babylon for another governor. Merbal was appointed, with the title of king, and reigned four years. He was fucceeded by his brother Iram, or Hiram, in 550 B.C.; and in the 14th year of his reign, Cyrus, according to the Phœnician annals, made himfelf mafter of the Perfian empire. At this time Phœnicia comprehended the whole coaft from the vicinity of Aradus northwards to the frontiers of Egypt. It now became one of the provinces of Perfia, and without making any confpicuous figure in hiftory, it fuftained itfelf by its commerce. When Phœnicia at a fubfequent period was joined to Syria, it was governed by prefidents or rulers fent from Rome. Phœnicia was afterwards one of the provinces which Antony abandoned to Cleopatra; but after the death of both thefe, Auguftus, who paffed into Paleftine with Herod, granted to him feveral towns of Phœnicia. This province was one of the fcenes in which the apoftles and followers of Jefus Chrift preached the doctrines of Chriftianity; but the hatred of the Jews againft the Chriftians excited great troubles: the whole country was in arms, and the Jews revolted againft the Romans, till at length Jerufalem was taken by Titus. The fucceeding emperors diftinguifhed fome of the towns of Phœnicia by their attention. Tyre, among others, received from Adrian, and alfo from Severus, the title of Metropolis; fo that Phœnicia, having its metropolis, was detached from the government of Syria. Under the reign of Theodore, and under that of Arcadius, this province was divided into two diftinct parts: one was called "Maritime Phœnicia," or fimply "Phœnicia;" and the other, "Phœnicia of Libanus." Maritime Phœnicia had for its metropolis Tyre, on which depended Sidon, Ptolemais, Berytas, Biblos, Tripolis, Arca, Orthofia, Botrys, Aradus, Antaradus, Porphyrion, Paneas, and Sylaminum. Phœnicia of Libanus had for its metropolis Damas, to which were fubordinate Laodicea, Abila, Heliopolis, Jabrunda, Palmyra, Emifa, Danaba, Evaria, Comoara, Cotada, and Sarracene. Chriftianity flourifhed for fome time in this province, till at length the Arabs gained poffeffion of it; and Phœnicia, having embraced a new worfhip, was governed by different dynafties of Arabian princes.

Phœnice, one of the names which, according to Pliny, was given to the ifle of Tenedos.

PHŒNICIAN Character. See Character.

PHŒNICON, in *Ancient Geography*, a town of Egypt, on the route from Coptos to Berenice, between Coptos and Didyme, according to Antonine's Itinerary.

PHŒNICOPTERUS, *Flamingo*, in *Ornithology*, a genus of birds of the order Grallæ, of which the generic character is, bill naked, toothed, bent as if broken; noftrils linear; feet four-toed, palmate, the membranes femicircular on the fore part; the hind toe is not connected with the others. There are two fpecies mentioned by Gmelin. The birds of this genus combine the characters of the Anferes and Grallæ. They have long legs and neck; the bill is large; the upper mandible carinate above, and toothed on the edge; lower compreffed, tranfverfely furrowed; the noftrils are covered with a thin membrane.

Species.

Rubra, or Common Red Flamingo. This is fpecifically defcribed as having its quill-feathers black. It inhabits Africa and South America. From the top of the bill to the end of the tail it is four feet four inches long, and to the end of the legs fix feet; it feeds on aquatic infects and fifh; perpetually twifts its neck about when eating, fo that the upper mandible touches the ground; it makes its neft on hillocks in fhallow water, on which it fits with the legs hanging down, like a man fitting upon a ftool; it lays two white eggs; is very impatient of cold; the flefh is good, efpecially the tongue; it changes its colour with its age, being the firft year of a white afh, the fecond rofy, the third full fcarlet; tongue covered with about twelve papillæ, which are hooked backwards, and cartilaginous at the tip. The young ones run about with great fwiftnefs, but are unable to fly till they have attained nearly their complete growth. They fubfift chiefly on fmall fifhes, ova, and water infects; and frequent during the day the borders of rivers and lakes, withdrawing at night to the high grounds, and lodging amidft long grafs. Flamingoes are extremely fhy, and are faid almoft always, unlefs in the breeding feafon, to keep together in flocks, having a centinel ever vigilant at his poft, by whom the flighteft approaching danger is announced, by intimations which produce immediate flight. Their flefh is thought by fome not to be inferior to that of the partridge.

Chilensis; Chili Flamingo. Quill-feathers white. It inhabits Chili; it is five feet long from the bill to the claws; the bill is covered with a reddifh fkin; head fubcrefted.

PHŒNICOPUS Gallinula, a name by which fome authors have called a bird, more ufually known by the name tringa.

PHŒNICUM, in *Ancient Geography*, a town of Arabia Felix, upon the coaft of the Elanitic gulf, between Hippos and Ahaunathi. Ptolemy.

PHŒNICURUS, in *Ornithology*, a fpecies of *Motacilla;* which fee. See alfo Motacilla *Erithacus* and *Suecica*.

PHŒNICUS Mons, in *Ancient Geography*, a mountain of Afia Minor, in Lycia. According to Strabo, it was alfo called Olympus.

Phœnicus *Portus*, a port of the Peloponnefus, in Meffenia, near the promontory Acritas, fouth-weft of Colonis.—Alfo, a port of the fea, on the eaft coaft of Sicily, near the promontory Pachynus. Ptolemy.—Alfo, a port of the nome of Libya. Ptol.—Alfo, a port on the fouthern coaft of the ifle of Crete. Ptol.—Alfo, a port of Afia Minor, on the coaft of Lycia, two miles from the town of Patara. Livy.—Alfo, a port of Afia Minor, on the coaft of Ionia, at the foot of the promontory Mimas.

PHŒNICUSA, or Phœnicodes, one of the feven Æolian ifles of the ancients, called *Felicuda*, fituated towards the weft, to the eaft of the ifle of Ericufa. It took its name, according to Strabo, from its production, which was the phœnix or palm-tree. See Felicuda.

PHŒNICUSSÆ, a town of Afia, in Syria, which belonged to the Phœnicians.—Alfo, the name of two iflands, placed

placed by Steph. Byz. on the coast of Africa, in the gulf of Carthage.

PHŒNIGMUS, φοινιγμος, in *Medicine*, from φοινιξ, *red*, signifies properly that *redness of the skin*, which is occasioned by certain stimulating substances, mustard, cantharides, &c. which have been therefore called *rubefacients*. The appellation of *phœnigmus* has also been sometimes given to the rubefacient substance itself.

Sauvages has applied the term to a disease, which consists of red or purple spots or blotches upon the skin, without any elevation, inflammation, or fever. His phœnigmus is, in fact, the *petechiæ sine febre* of some writers, and the Purpura simplex of Dr. Willan. See PURPURA. See Sauvages, Nosol. Method., class x. gen. 32.

PHŒNIX, Φοινιξ, in *Astronomy*, a constellation of the southern hemisphere; unknown to the ancients, and invisible in our northern parts.

The number of stars in this constellation is thirteen. See CONSTELLATION.

This constellation took its name and form from that of a bird famous among the ancients; but generally looked upon by the moderns as fabulous.

The naturalists speak of this bird as single, or the only one of its kind. They describe it as of the size of an eagle; its head finely crested, with a beautiful plumage; its neck covered with feathers of a gold colour, and the rest of its body purple; only the tail white, intermixed with carnation; and its eyes sparkling like stars. They hold, that it lives five or six hundred years in the wilderness; that, when thus advanced in age, it builds itself a funeral pile of sweet wood, and aromatic gums; then it fires it with the wafting of its wings, and thus burns itself; and from its ashes arises a worm, which, in time, grows up to be another phœnix.

Hence the Phœnicians gave the name phœnix to the palm-tree; because, when burnt down to the very root, it naturally rises again fairer than ever.

Ancient historians reckon four appearances of the phœnix: the first, in the reign of Sesostris; the second, in that of Amasis; the third, in that of the third Ptolemy; and the fourth, according to Dion Cassius, as a presage of the death of Tiberius, but Tacitus refers it to Egypt under the empire of Tiberius, and Pliny to the consulate of Quintus Plancius, which took place A.D. 36.

The ancients, however, speak of the phœnix as a fabulous bird.

The ancient Christians refer to the phœnix in some of their accounts of the resurrection.

PHŒNIX, in *Botany*, φοινιξ of the ancient Greeks, the Date Palm-tree; from which, as a primitive word, Phœnicia, the land of Palm-trees, seems to have derived its name; as likewise perhaps the red colour *phœniceus* or *puniceus*, from the hue of the sheath when arrived at maturity; which etymology seems to us the more probable, as *puniceus* is sometimes made synonimous with *croceus*, saffron-coloured. Linn. Gen. 573. Schreb. 776. Willd. Sp. Pl. v. 4. 730. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 5. 369. Juss. 38. Lamarck Illustr. t. 893. Gærtn. t. 9.—Class and order, *Dioecia Triandria*. Nat. Ord. *Palmæ*.

Gen. Ch. Male, *Cal.* General sheath of one valve, including a branched stalk. Perianth deeply three-cleft, minute, permanent. *Cor.* Petals three, concave, ovate, rather oblong. *Stam.* Filaments three, very short; anthers linear, quadrangular, the length of the corolla.

Female either on a different plant, or on the same common stalk. *Cal.* and *Cor.* as in the male. *Pist.* Germen superior, roundish; style awl-shaped, short; stigma acute. *Peric.* Drupa ovate, of one cell. *Seed* solitary, bony, elliptic-ovate, marked with a longitudinal furrow, nearly opposite to the dorsal embryo.

Eff. Ch. General sheath of one valve.

Male, Calyx in three deep segments. Petals three.

Female, Calyx in three deep segments. Petals three. Pistil one. Drupa ovate.

1. Ph. *dactylifera*. Common Date Palm-tree. Linn. Sp. Pl. 1658. Ait. n. 1. Stokes Mat. Med. v. 4. 519. (Palma; Kæmpf. Amoen. 667. t. 1, 2, 3. Matth. Valgr. v. 1. 198, 200. Camer. Epit. 124. Ger. Em. 1517.)—Leaves pinnate, without thorns; leaflets linear-lanceolate, folded, straight.—Native of the Levant. Though it has been cultivated in our stoves for above 200 years, no individual has yet been preserved long enough to blossom, and very few have become caulescent. In the south of France this plant forms a handsome tree, but brings no fruit to perfection. It is well known, that as the male and female flowers are generally the produce of distinct individuals, the two sexes require to be cultivated together, in order to obtain good fruit; and in this chiefly consists the culture of the Palm-tree. Hence the Linnæans have derived one of their most striking proofs of the sexes of plants, the fact being recorded by those who were not instructed in that doctrine. (See FECUNDATION, and SEXES *of* PLANTS.) For an account of the fruit, see DATE. The tree is of slow growth, but gradually attains a very lofty stature, consisting of a straight simple scaly *trunk*, crowned with a noble spreading evergreen tuft of long, pinnate, rigid, smooth *leaves*. (See PALMÆ.) Several axillary drooping bunches of innumerable white *flowers*, each bunch enveloped in a large coriaceous *sheath*, proceed from the crown of the *stem*, and produce an ample crop of *dates*, which are gathered in the East with great care and ceremony, constituting an important article of food, as well as of commerce. Their quality is as various as that of apples, or any other cultivated fruit. An ample and complete history of this valuable tree, and its whole economy, is to be found in Kæmpfer.

2. Ph. *reclinata*. Reclining Date Palm-tree. Jacq. Fragm. 27. t. 24. Ait. n. 2.—Leaves pinnate, without thorns; leaflets linear-lanceolate, folded, loosely spreading. —Native of the Cape of Good Hope, whence it was sent to Kew by Mr. Masson, in 1792. It is kept in the greenhouse, but has not flowered.

3. Ph. *farinifera*. Small Date Palm-tree. Roxb. Coromand. v. 1. 53. t. 74. Ait. n. 3.—Leaves pinnate, without thorns; leaflets linear-awlshaped, folded. Flowers with six stamens and three styles.—Native of Coromandel, chiefly found in dry barren sandy places, not far from the sea, flowering in January and February, and ripening fruit in May. The *trunk* is not above one or two feet high, and entirely enveloped in *leaves*, which resemble those of the first species in general appearance, but are more pointed, and of a much deeper green. The common flower-stalk, or *spadix*, bears numerous simple *branches*, each from eight to twelve inches long, beset with a great number of sessile *flowers*; the male white; the female green, on a separate tree. The *stamens* are six, with a three-cleft rudiment of a *pistil*. The *pistil* of the female flowers is three-cleft, and there are rudiments of three *seeds*, as Dr. Stokes well remarks; all which does not accord with the generic character, taken from the first species. Yet Dr. Roxburgh says the *pistil* is "as in *Phœnix dactylifera*." Probably the character of the latter requires emendation, for which we can only look to some tropical botanist. The *fruit* of the present species is a purple single-seeded *drupa*, the size of a large French bean, containing a small quantity of sweet mealy

mealy pulp, and is eaten by the natives of the coaſt of Coromandel, without any preparation. The *ſtem* of the plant contains a large quantity of farinaceous ſubſtance, among the woody fibres, affording an inferior ſort of ſago, to which recourſe is had in times of ſcarcity; but Dr. Roxburgh deſcribes it as bitteriſh, and inferior in nutritious qualities to real ſago. This ſpecies is cultivated at Kew, having been procured from India in 1800, by Sir Joſeph Banks.

Ph. *puſilla*, Lour. Cochinch. 614. Gærtn. v. 1. 24. t. 9, anſwers very nearly to the deſcription of the laſt, except that the *ſtyle* is ſaid to be ſhort, and *ſtigma* ſimple. Perhaps the young *ſtyles* cohere, and appear to be only one. Gærtner's figure indicates the rudiments of three *ſeeds* in the *germen*, as in Roxburgh's plant.

Phœnix, in *Gardening*, contains a plant of the evergreen exotic tree kind, of which the ſpecies cultivated is the date palm-tree (P. dactylifera).

Method of Culture.—This plant may be increaſed by ſeed, procured from abroad, or taken out of the fruit, which ſhould be ſown as ſoon as poſſible in pots of light rich earth, plunging them in a tan hot-bed in the ſtove, giving moderate waterings; when they ſoon come up. And when a few inches high, they ſhould be pricked out into ſeparate ſmall pots, plunging them into the hot-bed or bark-bed, where they muſt remain, giving frequent waterings, and ſhifting them into larger pots, according as their progreſs of growth may require. When they are removed, great care ſhould be taken not to injure their large roots, or to over-pot them.

This, like the reſt of the palm tribe, has no other branches than its large leaves, each of which is compoſed of a leaf and branch, always ariſing from the top; and as the old leaves fall, the ſtem forms itſelf, and advances in height. But although the leaves grow very tall in a few years, the ſtem advances but ſlowly, and can never be expected to arrive at a flowering and fruiting ſtate in this climate: it, however, merits a place in the hot-houſe collections for its ſingularity.

The berries of this tree are the dates of the ſhops, which are imported from Africa, and the countries in the Levant.

Phœnix, φοινιξ, among the *Ancients*, a muſical inſtrument, not unlike the *cithara;* which ſee. See alſo Phænix.

Phœnix, in *Geography*, a port of Aſia Minor, on the coaſt of Lycia.—Alſo, a mountain of Aſia, in the Doride. —Alſo, a town of Italy, according to Appian.—Alſo, a river of Greece, in Theſſaly, which ran into the Apidanus.— Alſo, a river of the Peloponneſus, in Achaia, which had its mouth ſouth-weſt of the gulf of Corinth.

PHŒOPUS, in *Ornithology*, a name uſed for two different birds; the one called by the Germans *brachvogel*, and the other the *whimbrell*, or *arquata minor*, the ſmall curlew of authors.

The firſt of theſe, or the *brachvogel*, is of a deep black colour, ſpotted with a yellowiſh and reddiſh-brown; its beak is long, ſlender, and black, and is moderately bent; its neck is grey, tending to reddiſhneſs towards the bottom; and its belly is white. Mr. Ray ſuſpects this not eſſentially to differ from the other, but the ſight of the bird alone can determine that. See Scolopax *Arquata*.

PHOGOR, in *Ancient Geography*, a mountain of Paleſtine, on the other ſide of Jordan.—Alſo, a town of Paleſtine, in the tribe of Judah, near Bethlehem.—Alſo, another town north-eaſt of the Dead ſea and of Livias.

PHOKWARAH, in *Geography*, a town of Hindooſtan, in Lahore; 50 miles E. of Sultanpour.

PHOLAS, in *Conchology*, a genus of the claſs and order Vermes Teſtacea. The generic character is, animal an aſcidia; ſhell bivalve, divaricate, with ſeveral leſſer differently ſhaped acceſſory ones at the hinge; the hinge recurved, united by a cartilage; in the inſide, beneath the hinge, is an incurved tooth. There are twelve ſpecies. The inhabitants of this genus all perforate clay, ſpongy ſtones, and wood, while in the younger ſtate; and as they increaſe in ſize, they enlarge their habitation within, and thus become impriſoned. They contain a kind of phoſphoric liquor, of great brilliancy in the dark, which illuminates whatever it happens to fall on.

The word pholas is derived from the Greek φωλεω, and ſignifies no more than any thing which is hidden; the name was given to this genus of ſhell-fiſh from their cuſtom of making themſelves holes in earth, ſand, ſtones, or wood, and living hidden in them. Many being of opinion, that theſe could not work themſelves into the ſubſtance of hard ſtones, have thought that they were hatched in holes accidentally formed in ſtones, and that the ſhells naturally grew of ſuch a ſhape as was neceſſary to fill the cavity. Nor is this the only error propagated concerning the pholas; for as all that was ſignified by the name being only that the ſhell was hidden in ſome ſolid ſubſtance, whenever an author found a ſhell-fiſh of whatever kind thus buried in ſtone, he deſcribed it under the name of pholas.

Species.

* Dactylus. Shell oblong, with reticulate ſubſpinous ſtriæ on the upper part. It is found among rocks in this country, and other parts of Europe, and ſhines by night. It is about five inches long; entirely white, with ſometimes an ochraceous caſt, thin, fragile, elongated, and wedge-ſhaped on the fore part, convex behind, the margin inflected; it is marked with ſubſpinous ſtriæ, which become gradually more indiſtinct; the hinge reſembles a ſpoon, and there are four acceſſory valves.

Costata. Shell ovate, and ſtriate with elevated ribs. It inhabits the American ſeas. It is white, and almoſt ſix inches long; the ribs are oblique, and armed with elevated ſcales or obtuſe ſpines.

Striata. Shell ovate, and multifariouſly ſtriate. This ſpecies is found in ſome of the ſouthern parts of Europe and India, and the coaſt of Barbary. The ſtriæ are occaſionally decuſſate; the part near the hinge is glabrous, and without ſtriæ.

Candida. Shell oblong, and muricate on all parts with decuſſate ſtriæ. This inhabits European and American ſeas, and is very thin; it is ſilvery within, and more glabrous; rounded at each end; tooth of the hinge is ſlender and cleft; length near an inch, the breadth an inch and a half.

Pusilla. Shell oblong, rounded with arched ſtriæ. It is found in different parts of India and America, and penetrates the bottoms of ſhips. The ſhell is browniſh or white, gaping on the fore part, globular under the top, and marked with reticulate knotty ſtriæ.

* Crispata. Shell oval, the part next the hinge more obtuſe, waved, and ſtriate; teeth of the hinge curved, large, and ſtrong. A variety is known by the ſhell being thinner and ſmaller; the tooth alſo is ſlender and oblique. It inhabits European ſeas, is about two inches long, and three and a half broad. The primary ſhells are divided by a tranſverſe wrinkled groove in the middle; the acceſſory ones are ſmall.

Orientalis. Shell oblong, with a ſtraight margin; one-half of it is quite ſmooth, the other with reticulate ſtriæ. It inhabits Siam and Tranquebar; is large and thin; the ſhells gape at one end only, and they are marked within with reticulate ſtriæ.

Campechiensis. The ſhell of this ſpecies is narrow, white, and very finely ſtriate. It inhabits the bay of Campeachy. It is probably not a diſtinct ſpecies.

Cordata. Shell ſhort, turgid, and furrowed with fine elevated tranſverſe ſtriæ; aperture heart-ſhaped. It is found affixed to the Corals. The ſhell is very thin, fragile, and of a dirty white; the fore part is ſmooth, except a few arched ridges.

Chilensis. Shell oblong, a little depreſſed, with diſtant longitudinal ſtriæ. It is found about the rocks of Chili. The ſhell is five inches long, with minute appendages.

Teredula. Shell oblong, white, with a longitudinal brown granulate ſuture. It inhabits the Belgic ſhores, and penetrates timber.

Hians. Shell bivalve, white, with tranſverſe arched ſtriæ; above connivent, convex in the middle, beneath wedge-ſhaped, with a very large oval aperture. It inhabits the American iſlands, and perforates calcareous rocks and corals.

As to the luminous quality of this ſpecies of ſhell-fiſh, obſerved by Pliny, and by modern naturaliſts, ſee Dactylus.

For an account of a particular ſpecies of pholas, called by Dr. Parſons *pholas conoides*, by others *pholas lignorum*, and in Dutch *wood-muſcle*, becauſe it is found burrowed in timber, ſee Phil. Tranſ. vol. lv. p. 1, &c.

PHOLIDIA, in *Botany*, from φολις, φολιδος, *the ſcale of a fiſh or ſerpent;* alluding to the ſcalineſs of the corolla. Brown Prodr. Nov. Holl. v. 1. 517.—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Myoporinæ*, Br.

Eſſ. Ch. Calyx deeply five-cleft, unchanged in the fruit. Corolla funnel-ſhaped; tube longer than the calyx; throat dilated, tumid at one ſide; limb ſhort, irregular; its upper lip two-lobed, recurved; lower ſpreading, in three deep equal ſegments. Stamens included. Anthers bearded. Stigma capitate, emarginate. Drupa dry, of four cells, with four ſeeds.

1. Ph. *ſcoparia*. Found by Mr. Brown, on the ſouth coaſt of New Holland. A ruſh-like ſhrub, with oppoſite awl-ſhaped *leaves*. *Stalks* ſingle-flowered, axillary, ſolitary, without *bracteas*. *Corolla* blue, clothed externally with minute ſcales. *Albumen* thin.

PHOLIS, in *Natural Hiſtory*, the name of a genus of foſſils of the claſs of the gypſums or plaſter-ſtones, the diſtinguiſhing characters of which are, that the bodies of it are conſiderably hard, compoſed of ſomewhat broad particles, and of a bright cryſtalline luſtre.

The word is derived from φολις, *a ſcale*, or *ſmall flake*, from theſe bodies being compoſed of particles of that form.

The ſpecies of this genus are the moſt valuable of all the gypſums, as burning to the beſt and fineſt plaſter; but ſo far as is yet known, there are but two of them: the fine plaſter-ſtone of Montmartre in France, called by us *plaſter of Paris ſtone*, and *parget;* and the other the coarſer and ſomewhat reddiſh kind, common in many parts of England, and called *hall plaſter*. Hill. See Parget.

Pholis, in *Ichthyology*, the name of a ſmall anguilliform fiſh, the back of which is brown, the belly white, and the whole back and ſides ſpotted, and the ſkin ſoft and not covered with ſcales, but with a tough mucilaginous matter like the eel.

This moſt of all approaches to the alauda, and though uſually ſomewhat larger, yet Mr. Ray doubts whether it really differs from it in any thing eſſential; its great diſtinction being its colour, which, though a very obvious, is a very precarious one.

This is the Blennius *Pholis* of Gmelin, and the blennius of Artedi, with the top of the head acuminated, and the upper jaw the larger, the alauda non criſtata of Rondeletius and Geſner, the mulgraave and bulcaud of Willughby and Ray, and the ſmooth blenny of Pennant. It is found on the ſhores of the European ocean and Mediterranean ſea, and at the mouths of rivers among rocks and algæ, &c. See Blennius.

PHOLLIDES, a word uſed by the ancient phyſicians for ſoft and fungous tumours of the legs, ſuch as thoſe of people in an anaſarca, or leucophlegmacy.

PHOLLIS, as a coin. See Folis.

PHOLOC, in *Ancient Geography*, a mountain of Triphylia, ſouth of Onus.—Alſo, a mountain of Greece, in Theſſaly, where Hercules is ſaid to have ſlain the Centaur. —Alſo, a ſmall town of the Peloponneſus, in Arcadia, weſt of the river Erymanthe, according to Pliny and Mela. A mountain of the ſame name was ſituated near it to the weſt, which was the boundary of the Elide.

PHOMOTHIS, a town of Aſia, in the Mareotide, according to Ptolemy.

PHONASCIA, Φωνασκια, derived from φωνη, *voice*, the art of forming the human voice.

In ancient Greece, there were combats or conteſts eſtabliſhed for the voice, as well as other parts of the gymnaſtice.

The combats continued to be held in the time of Galen; and they were theſe that brought the phonaſcia into vogue. Hence the maſters of this art, and thoſe who taught the art of managing the voice, were called *phonaſci*, φωνασκοι; and under their tutorage were put all thoſe deſtined to be orators, ſingers, comedians, &c.

PHONIA, in *Geography*, a town of European Turkey, in the Morea; 22 miles W.S.W. of Corinth.

PHONICS, Φωνικα, derived from φωνη, *voice*, or *ſound*, the doctrine or ſcience of *ſounds* (which ſee); otherwiſe called *acouſtics;* which ſee.

Phonics may be conſidered as an art analogous to optics; and may be divided, like that, into *direct*, *refracted*, and *reflected*. Theſe branches the biſhop of Ferns, in alluſion to the parts of optics, denominates *phonics*, *diaphonics*, and *cataphonics*.

Phonics is improveable, both with regard to the object, the medium, and the organ.

As to the object, ſound, it may be improved, both with regard to the production and the propagation of ſounds. The firſt, in ſpeaking or pronouncing, in whiſtling or ſinging, or hallooing or luring, which are all diſtinct arts, and all improveable. The ſecond, by the poſition of the ſonorous body.

With regard to the medium, phonics may be improved by the thinneſs and quieſcency thereof, and by the ſonorous body being placed near a ſmooth wall, either plane or arched, eſpecially cycloidally or elliptically: whence ariſes the theory of whiſpering places.

Add to theſe, that by placing the ſonorous body near water, its ſound is mollified; that by placing it on a plain, the ſound is conveyed to a greater diſtance than on uneven ground, &c.

As to the organ, which is the ear, it is helped by placing it it near a wall, eſpecially at one end of an arch, the ſound beginning at the other; or near the ſurface of water, or that of the earth.

And alſo by inſtruments, as the ſtentorophonicon, or ſpeaking-trumpet.

Alſo by an inſtrument to help weak ears as ſpectacles do eyes; by an inſtrument to take in vaſtly remote ſounds, as teleſcopes do objects; by a microphone, or magnifying ear-inſtrument; and by a polyphone, or multiplying ear-inſtrument.

Cataphonics, or reflected hearing, may be improved by ſeveral kinds of artificial echoes; for, in general, any ſound falling, either directly or obliquely, on any denſe body of a ſmooth ſurface, whether plain, or arched, is beat back again, or reflected, *i. e.* it echoes more or leſs. See Echo.

PHONICUM Centrum. See Centrum.

PHONOCAMPTICUM Centrum. See Centrum.

PHOORY, in *Geography*, a town of Hindooſtan, in Baglana; 28 miles S. of Zolnani.

PHORA, in *Ancient Geography*, a town of Aſia, in Greater Armenia, between Taſco and Mapa, according to Ptolemy.

PHORAGA, a town of Aſia, in Aria. Ptolemy.

PHORBÆ, a town of Theſſaly, which belonged to the Achæans; called alſo *Phorbas*.

PHORBANTIA, an iſland on the coaſt of Sicily. Ptolemy.

PHORBANTIUM, a mountain of Theſſaly, in the Trazena. Steph. Byz.

PHORBEIA, φορβεια, a muſical inſtrument of the ancients, implies a *capiſtrum* or leather bandage, with which the players on the flute ſurrounded their heads. The phorbeia was placed before the mouth of the muſician, oppoſite to which was a ſlit for the reed to paſs through. See Flute.

This bandage was uſed for the purpoſe of augmenting the force of the wind, and not only to prevent the ſwelling the cheeks of the performer, but to prevent the wind from eſcaping at the ſides of the reed. See Capistrum.

PHORCYNUS, in *Ancient Geography*, a port of the iſle of Ithaca, mentioned by Homer, and alſo by Strabo.

PHORIMOS, a name given by ſome authors to roch alum.

PHORINE, a word uſed by ſome authors to expreſs the ſkin of a hog; ſome alſo underſtand it to mean a ſkin of any kind, extending it even to the human cutis.

PHORMINX, an ancient muſical inſtrument, ſeems to have been the largeſt kind of lyre. See Lyre.

PHORMIUM, in *Botany*, a name adopted by Forſter from the ancient Greeks, whoſe φορμιον was uſed for making mats, or baſkets, being ſo called from φορμος, *a baſket* or *pannier*. Forſter's plant ſerves for ſimilar purpoſes in New Zeeland. Forſt. Gen. t. 24. Linn. Suppl. 28. Schreb. 799. Willd. Sp. Pl. v. 2. 171. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 284. Juſſ. 52. (Lachenalia; Lamarck Illuſtr. t. 237. f. 2. Chlamydia; Gærtn. t. 18.)—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Aſphodeli*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* Petals ſix, obliquely aſcending, oblong, converging into a tube, united at the baſe, unequal; the three outermoſt acute, keeled; the three innermoſt longer, reflexed rounded and vaulted at the extremity, ſlightly emarginate. *Stam.* Filaments ſix, thread-ſhaped, aſcending, longer than the corolla; anthers erect, nearly triangular. *Piſt.* Germen ſuperior, oblong, obtuſely triangular; ſtyle thread-ſhaped, nearly erect, rather ſhorter than the ſtamens; ſtigma ſimple. *Peric.* Capſule oblong, pointed, with three furrowed angles, three cells and three valves; the partitions from the middle of each valve. *Seeds* numerous, imbricated in two rows along each partition, ovate, black and ſhining, compreſſed, bordered.

Eſſ. Ch. Corolla inferior, of ſix petals; the three inner ones longeſt. Stamens prominent. Capſule oblong, triangular. Seeds compreſſed, bordered.

1. Ph. *tenax*. New Zeeland Flax. Forſt. Prodr. 25. Linn. Suppl. 204. Cook's Voyage, v. 2. 96. t. 96. J. Mill. Ic. t. 2.—Native of New Zeeland and Norfolk Iſland. Hardy in our climate, flowering in June and July, but rarely. *Root* perennial, long, with many ſtrong fibres. *Stem* none. *Leaves* radical, numerous, erect, linear, acute, keeled, entire, ſmooth, four or five feet long, tough and rigid, of a glaucous green; ſtained with orange-colour about the lower part. *Flower-ſtalk* radical, branched, many-flowered. *Flowers* yellow, each about an inch and a half long. *Capſule* three inches long. Very ſtrong and good thread may be manufactured from the fibres of the leaves.

PHORMORAPHIS, in the *Materia Medica*, a name often uſed by the later Greek writers, and generally looked on as one of their unintelligible words, or the name of ſome drug not known at this time. See Carpesia.

PHORONICUM, in *Ancient Geography*, a name given by Pauſanias and Steph. Byz. to a town of Argos, the capital of the Argolide.

PHORONOMIA, derived from φορα, *motion*, and νομος, *law*, is a ſcience comprehending the laws of motion, both of ſolids and fluids. The work of Hermannus, printed at Amſterdam in quarto, in 1715, under this title, is well known.

PHORONTIS, in *Ancient Geography*, a town of Aſia Minor, in Caria. Pliny.

PHORUM, a port of Greece, in Attica, in the vicinity of Pſyttalia. Strabo.

PHOS, a word uſed by ſome medical writers to expreſs a diſtemperature of the eye, in which there is ſeen a black circle wholly ſurrounding the pupil.

PHOSCAS, in *Ornithology*, a name of a freſh-water fowl of the duck kind, and of the ſize of the common wigeon. Its body is remarkably flat; its beak and legs are blue; its head and neck are of a browniſh colour, variegated all over with numerous triangular black ſpots.

PHOSGENE Gas, in *Chemiſtry*, a ſpecies of gas lately diſcovered by Mr. John Davy, in his efforts to unite together the carbonic oxyd and the oxymuriatic gaſes. Some unſucceſsful attempts had been made for this purpoſe by Meſſrs. Gay-Luſſac and Thénard, and afterwards by Mr. Murray of Edinburgh. Mr. Davy accompliſhed this object apparently without any difficulty. The gaſes were put in contact and expoſed to a bright light for a quarter of an hour; when the mixture was diminiſhed to half its original bulk, and a gas was left, which poſſeſſed ſeveral remarkable properties. It is compoſed of equal volumes of chlorine and carbonic oxyd gaſes, condenſed into half their bulk. It is colourleſs; and has a ſtrong diſagreeable ſmell. Its ſpecific gravity is 3.669; and 100 cubic inches, under a mean temperature and preſſure, weigh 111.91 grains; hence it is by far the heavieſt gas at preſent known. It reddens vegetable blues. It combines with ammonia, condenſing four times its bulk of that gas, and forming a peculiar neutral ſalt. Phoſgene gas is decompoſed by water, and by moſt metallic bodies. It is an acid of a very peculiar nature, and deſerves a much more complete examination. As this gas has been hitherto produced only by the action of light, Mr. Davy propofed to name it "phofgene." Phil. Tranf. for 1812, part i.

PHOSPHATS, are falts formed by the phofphoric acid, with the different faline bodies. See the refpective bafes, as POTASH, SODA, &c.

PHOSPHITES, falts formed by the phofphorous acid combining with the bafes of falts.

PHOSPHOLITE. See APATIT.

PHOSPHORI, or *Phofphorefcent Subftances*, may be diftributed into three claffes. The firft comprehends thofe which require a previous expofure to the folar or other light, in order to become luminous; on which account they are called "folar phofphori." See PHOSPHORUS.

The fecond clafs includes thofe which, without any neceffary previous expofure to light, become luminous when moderately heated; thefe, by way of diftinction, may be denominated "phofphori from heat." Thefe differ from the former in that, after having been continued at any particular temperature till their luminoufnefs is exhaufted, they are incapable of becoming again luminous, except at a greater heat than that to which they were firft fubjected. The range of temperature at which thefe bodies become luminous, commences at about 400° Fahr., and terminates at the loweft vifible red heat. In fome the light is almoft momentary; in others it remains many minutes. The intenfity of the light appears to be unalterable, whether the body that emits it be in a Torricellian vacuum, or plunged in any of the natural or artificial gafes. The following fubftances are arranged by Mr. T. Wedgwood, according to the brilliancy of their light. See Phil. Tranf. vol. lxxxii. p. 28.

The moft phofphorefcent of all fubftances by heat, is that variety of the blue fluor of Derbyfhire, which when fcraped or ftruck emits a fetid bituminous odour; it glows, when moderately heated with a pale emerald green light, fufficiently intenfe to be very vifible even in day light. To the fecond rank belong the common fwine-ftone, the common blue fluor, and red felfpar, all of which, as well as thofe that follow, exhibit a white or reddifh light. The third clafs includes the diamond, the ruby, carbonated barytes, chalk, colourlefs calcareous fpar, fea-fhells, granite, and white fluor. The fourth clafs comprehends white fand, carbonated magnefia, heavy fpar, flint, white marble, quartz, porcelain, and earthen ware. The fifth clafs includes moft of the metals, fulphat of potafh, borax, white paper, white linen, fawduft, and afbeftos. Under the fixth and laft clafs are comprehended oil, wax, fpermaceti, and butter when nearly boiling. To exhibit with the greateft effect the luminous property of thefe bodies, the harder ones fhould be coarfely pulverifed and fprinkled in a dark room on the furface of a thick metallic plate, heated below rednefs. A very ftriking exhibition of the phofphorefcence of the fetid blue fluor may be made by heating fome oil in a clear flafk till it becomes luminous, and then dropping in about a teafpoonful of pulverifed fluor; at the inftant when this latter comes in contact with the hot liquid, a bright flafh of green light is given out, which may be renewed for many times, by repeatedly fhaking the veffel. Moft of the fubftances above mentioned, are phofphorefcent alfo by friction. Sir H. Davy has alfo obferved, that if fluor be heated till it ceafed to become luminous, it is ftill capable of producing light by collifion; and it is obferved, that certain other bodies, as tremolite, and a particular variety of blende, give out much light even from the fcratch of a pin.

The third clafs of phofphorefcent fubftances, confifts of thofe which, belonging to the animal and vegetable kingdoms, emit light fpontaneoufly at the common temperature, without the neceffity of previous expofure to light: thefe may be denominated "fpontaneous phofphori." Animal fubftances exhibit this appearance before the commencement of putrefaction; and it ceafes when the putrefaction is complete. Among thofe who have directed their attention to this fubject, we may reckon Boyle, Canton, and Dr. Hulme. See LIGHT.

PHOSPHORIA, Φωσφορια, in *Antiquity*, a feftival in honour of Phofphorus or Lucifer.

PHOSPHORIC ACID, in *Chemiftry*. This acid is found in combination with lime, foda, and ammonia in animal fubftances, and is alfo a component part of feveral minerals. It may be obtained, but not in a ftate of purity, from the bones of animals. For this purpofe, the bones are firft burned to whitenefs in a red heat, and then reduced to a fine powder. This powder is decompofable by the fulphuric acid, by which means the phofphoric is fet free in the liquid form, while the fulphat of lime is infoluble. This liquid, however, is found not to contain the phofphoric acid pure, but combined with fome lime. Hence this procefs is not reforted to for getting pure phofphoric acid. The following is unobjectionable.

Into fome hot nitric acid project fmall bits of phofphorus, 'till no more effervefcence takes place. The nitric acid is decompofed, giving the whole of its oxygen to the phofphorus, while the nitrogen which conftitutes the effervefcence efcapes in the form of gas. A thickifh fluid refults from this procefs, which, when evaporated in a platina crucible, ftill thickens till it is raifed to a red heat. On cooling it affumes the folid form, and is tranfparent like glafs. This is the pure phofphoric acid, which in this form is alfo called phofphoric glafs. It poffeffes all the effential properties of an acid. It has a fharp acid tafte, and changes vegetable blues to red.

Its affinity for water is fuch that it foon deliquefces in the air, exhibiting the fame vifcid oily appearance which it poffeffed before evaporation. It has no fmell, not being volatile at lefs than a red heat, when it exhales in the form of white fmoke.

In the ftate of glafs its fpecific gravity is 2.516, which will be lefs in the liquid form as it contains more water.

It diffolves readily in water, producing heat, though much inferior to that produced by the combination of the fulphuric acid with water; a proof that the former has lefs attraction for water.

This acid is known to confift of 1 atom of phofphorus to 2 of oxygen. The atom of phofphorus being 9, and that of oxygen 7, will make the acid $9 + 14 = 23$, which is near the truth. It does not combine with more oxygen, although its affinity is great for that fubftance.

It is not decompofed in the cold by any of the inflammable bodies, the alkaline and earthy bafes excepted. Charcoal, zinc, and iron decompofe it, when affifted by a ftrong heat in a clofe retort, fetting the phofphorus free. It is in this way that phofphorus is obtained. In its dilute ftate it acts on feveral of the metals, as zinc, tin, and iron. They are firft oxydated by the water, when hydrogen gas is evolved. The acid then combines with the oxyd, forming falts, which are defcribed under their refpective bafes. It combines with the alkalies, earths, and the reft of the metallic oxyds.

The experiments of Lavoifier and Dalton agree in making the proportion of oxygen to be what has been already ftated. The former chemift found that 114 of the acid contained 69.375 of oxygen.

PHOSPHORIC *Matches*, or *Tapers*, are prepared by the following

following ſimple proceſs. Take a glaſs tube, four inches long, and one line in diameter, cloſed at one end. Introduce a ſmall quantity of phoſphorus into the tube, and puſh it to its farther end; after which, a taper covered with a ſmall quantity of wax is introduced into the ſame tube. The open end is then hermetically ſealed, and the other end is plunged into boiling water; upon which the phoſphorus melts, and fixes itſelf upon the match. A line is drawn at one end of the length of the tube, with a flint, that it may be broken, as occaſion may require. The match is to be drawn out quickly to inflame the phoſphorus.

The proceſs of M. Lewis Pegle for making the inflammable bougies conſiſts in taking a glaſs tube, five inches long, and two lines wide, one end of which is ſealed with a blowpipe. Small tapers of wax are prepared, with three double threads of cotton twiſted together. The extremity of the match or taper is half an inch long, and muſt not be covered with wax. A piece of lead is laid in a ſaucer filled with water; and upon this the phoſphorus is cut, beneath the water, into fragments of the ſize of a grain of millet. One of theſe grains is to be dried, and introduced into the tube of glaſs; after which the fortieth part of a grain of very dry ſulphur is to be added, that is, half the weight of the phoſphorus. One of the bougies is then taken, and its extremity dipped in very clear oil of wax. If too large a quantity riſes, it muſt be dried with a cloth. The match is introduced into the tube with a turning or twiſting motion between the fingers. The bottom of the tube muſt then be plunged into boiling water, to ſoften the phoſphorus; obſerving to keep it no longer than three or four ſeconds in the water. The other extremity of the tube is afterwards ſealed. Theſe bougies muſt be kept in a tin tube, to avoid the danger of inflammation.

Phosphoric *Bottles*, are formed by heating a glaſs bottle, and fixing it in a ladle full of ſand; and then two or three ſmall pieces of phoſphorus are introduced into it. A ſmall red-hot iron wire is uſed to ſtir the phoſphorus about, and cauſe it to adhere to the internal ſurface of the bottle, where it forms a reddiſh coating. The heated wire is introduced repeatedly; and when all the phoſphorus is thus diſtributed within the bottle, it is left open for a quarter of an hour. and afterwards corked. When this is uſed, a common match tipped with ſulphur is introduced into the bottle, turned round, and quickly drawn out. The phoſphorus which ſticks to the ſulphur takes fire, and lights the match.

The theory of this phenomenon depends upon the circumſtance, that the phoſphorus is ſtrongly dried, or half calcined, and needs only the contact of air to ſet it on fire.

As phoſphorus is ſoluble in oils, more eſpecially the volatile oils, theſe oils become luminous. If this ſolution be kept in a bottle, a phoſphoric flaſh, which emits a ſmall quantity of light, will be ſeen every time the bottle is opened. The oil of cloves is uſed in this operation. The combination of phoſphorus and oil appears to exiſt naturally in the glow-worm, or "lampyris ſplendidula" of Linnæus. Forſter of Gottingen obſerves, that the ſhining matter of the glow-worm is liquid. If the glow-worm be cruſhed between the fingers, the phoſphoreſcence remains on the finger. Henckel reports, in his eighth diſſertation of his "Pyritologia," that one of his friends of a ſanguine temperament, after having danced much, perſpired to ſuch a degree, that he thought his life in danger. While he undreſſed, lines of phoſphoric flame were ſeen on his ſhirt, which left yellow red ſpots behind them, reſembling the reſidue of burned phoſphorus. This light was long viſible.

A phoſphoric gas may be extracted from phoſphorus, which takes fire by the mere contact of air. It is to the diſengagement of a gas of this nature, that we may attribute the ignes fatui which play about burying grounds, and generally in all places where animals are buried and putrefy. It is to a ſimilar gas, that we may refer the inflammable air which conſtantly burns in certain places, and upon the ſurface of certain cold ſprings. Chaptal's Elem. of Chemiſtry, vol. iii.

PHOSPHORICAL Column. See Column.

PHOSPHOROUS Acid, in *Chemiſtry*. When phoſphorus is expoſed to the air in an open veſſel for a length of time, it gradually aſſumes the form of a thick fluid, of the appearance of oil. This is the phoſphorous acid. The ſlowneſs with which it combines with oxygen only allows it to combine with 1 atom of oxygen, by which it is conſtituted. Its atom is, therefore, 9 of phoſphorus with 7 of oxygen, equal to 16.

It is of a viſcid oily conſiſtence, having an acid taſte, and the ſmell of garlic.

When expoſed to heat ſome of the water evaporates, but the acid does not become concrete like the phoſphoric. In this ſituation the water is decompoſed. The oxygen combines with one portion of the phoſphorous acid, forming the phoſphoric acid. An atom of phoſphorus combines with the hydrogen, forming phoſphuret of hydrogen, which eſcapes in the form of gas. So that out of three atoms of phoſphorous acid, and one of water, two atoms of phoſphoric acid, and an atom of phoſphuretted hydrogen, are formed.

If the phoſphorous acid be expoſed to the air for a conſiderable length of time after it is formed, it is converted into phoſphoric acid.

When this acid with water is poured upon zinc, tin, or iron, the water is decompoſed as with the phoſphoric acid, but the hydrogen combines with phoſphorus, forming phoſphuretted hydrogen, which is known by the ſmell.

The ſulphuric acid, when aided by heat, gives an atom of oxygen, which converts it into the phoſphoric acid, while the ſulphurous acid eſcapes in the form of gas. The nitric acid produces a ſimilar change.

PHOSPHORUS, Φωσφορος, formed from φως, *light*, and φερω, *I bear*, a matter, which ſhines, or even burns, ſpontaneouſly, and without the application of any ſenſible fire.

Phoſphori are either *natural*, or *artificial*.

Phosphori, *Natural*, are matters which become luminous at certain times, without the aſſiſtance of any art or preparation.

Such are the glow-worms, frequent in our colder countries; lantern-flies, and other ſhining inſects, in hot countries; rotten wood; the eyes, blood, ſcales, fleſh, ſweat, feathers, &c. of ſeveral animals; diamonds, when rubbed after a certain manner, or after having been expoſed to the ſun or light; ſugar and ſulphur, when pounded in a dark place; ſea-water, and ſome mineral waters, when briſkly agitated; a cat's or horſe's back, duly rubbed with the hand, &c. in the dark; nay, Dr. Croon tells us, that upon rubbing his own body briſkly with a well-warmed ſhirt, he has frequently made both to ſhine; and Dr. Sloane adds, that he knew a gentleman of Briſtol, and his ſon, both whoſe ſtockings ſhone much after walking.

All natural phoſphori have this in common, that they do not ſhine always; and that they never give any heat.

The natural phoſphori are either foſſile, vegetable, or animal.

The foffile are, though very different in degree, fome forts of earths, white fand, limeftones, ftalactites, and feveral other figured ftones, ifland cryftals, flints, fome fpecies of agates, white arfenic; but no fort of metals, metallic or fulphureous bodies, as jet, amber, except the before-mentioned arfenic.

On the other hand, falts imbibe light, provided they are divefted of every metallic principle; otherwife not, though as pellucid as poffible. For this reafon none of the vitriols will imbibe light; but other falts will though with a confiderable difference as to quantity; for fal gem and rock falt imbibe very little; fea falt, if dry, and in cryftals, much more; and, in like manner, fal ammoniac, fal catharticum, and nitre yet more. This power is weak in the natron of the ancients, and alum; but brighteft of all in borax.

In the vegetable kingdom we find very few phofphori; that of dry rotten wood is weak and not lafting; it appears chiefly upon the edges and inequalities of the furface. But this is moft remarkable in the rotten wood of the firtree, and fome others, where, in the dark, you fee fhining fpots as big as tares; whereas in full light the whole furface appears alike. Some few bars are luminous, but not confiderably fo; but no fruits, feeds, or their meals. Cotton, and the cryftals of tartar, appear very bright, but fine loaf-fugar appears the moft luminous of all both without and within; gums and refins retain no light.

There is a vaft variety of phofphori in the animal kingdom, fuch as the bones and teeth; to thefe may be added the fhells of fifh, egg-fhells, the human calculus, bezoar, and thofe parts of animals in which the terreftrial principle is very predominant. But where there is a confiderable quantity of oily matter, as in the hoofs, horns, and feathers, no light is manifeft, or at leaft in a fmall degree. Light is vifibly retained by the fkins of feveral living animals. Water cannot be made to imbibe light, though ice does exceedingly well, and efpecially fnow.

Beccarius propofes fome queries concerning the natural phofphori, of which the firft is, in what and how great a light the object ought to be placed? He tried different phofphori, in different degrees of light, and found them imbibe moft light from the fun itfelf; next in quantity when the fky was clear; and the leaft in foggy weather. Thefe experiments fhould be made in the open air, and not in a houfe with the glafs-windows fhut; becaufe many bodies appear luminous when the light has come directly to them, which will not have that appearance when the light has paffed through the glafs. He laftly tried what light they would imbibe from very bright flame, and found that alabafter itfelf, which is faturated more than any fubftance by the fun's rays, imbibed exceedingly little. The next query is, how long thefe bodies fhould remain in the light to be fufficiently faturated? Four or five feconds were found the utmoft length of time required for that purpofe. The other query is, how long the received light will continue in thefe phofphori? It does not laft the fame time in all; but continues more or lefs, from two feconds to eight, in proportion to the ftrength of the phofphorus, and the quantity of light received.

But that which, of all natural phofphori, has occafioned the greateft fpeculation, is the

Phosphorus, *Barometrical*, or *Mercurial*. M. Picard firft obferved, that the mercury of his barometer, when fhaken in a dark place, emitted light; with this circumftance, that in fhaking the mercury with rapidity, fometimes above, and fometimes below its equilibrium with the air, the light was only feen when below it, where it appeared as if adhering to the upper furface.

But this light is not found in the mercury of all barometers; which occafions a great difficulty.

M. Bernouilli, upon examining the circumftances of this phenomenon, invented a folution of the fame; he imagines, that upon the mercury's defcending, the vacuum in the tube increafing, there iffues out of the mercury to fill up this excefs of vacuity, a very fine fubtile matter, before difperfed throughout the pores of this mineral; and that, at the fame time, there enters through the pores of the tube another fine matter: thus, the firft matter emitted from the mercury, and collected over its furface, ftriking impetuoufly againft that received from without, has the fame effect with Defcartes' firft element againft the fecond; that is, it produces the motion of light.

But why, then, is not the phenomenon common to all barometers? To this he anfwers, that the motion of the fubtile matter out of the mercury may be weakened, and prevented, by any heterogeneous matter collected on its upper furface, into a kind of pellicle, fo that the light fhould never appear, but when the mercury is perfectly pure. This reafoning feemed confirmed from the experiments of feveral barometers, which he made according to this plan; but the Royal Academy of Sciences, repeating experiments with barometers made after the fame manner, did not meet with the fame fuccefs; the light being found in fome, but not in others.

M. Homberg, therefore, conjectured, that the difference confifted in the different qualities of the quickfilver: in fome, he obferved, they ufed quick-lime to purify it; in others, fteel-filings. The mercury, then, rifing in the diftillation, and paffing through the lime, might take away fome parts thereof, capable, by their extreme fmallnefs, of lodging in its interftices.

Hence, as quick-lime always retains fome fiery particles, it is poffible, in a place void of air, where they fwim at liberty they may produce this luftre.

Mr. Haukfbee has feveral experiments on the mercurial phofphorus. Paffing air forcibly through the body of quickfilver, placed in an exhaufted receiver, the parts were violently driven againft the fide of the receiver, and gave all round the appearance of fire; continuing thus till the receiver was half-full again of air.

From other experiments he found, that though the appearance of light was not producible by agitating the mercury in the fame manner in the common air, yet that a very fine medium, nearly approaching to a vacuum, was not at all neceffary.

And, laftly, from other experiments he found, that mercury inclofed in water, which communicated with the open air, by a violent fhaking of the veffel wherein it was inclofed, emitted particles of light in great plenty, like little ftars.

By including the veffel of mercury, &c. in a receiver, and exhaufting the air, the phenomenon was changed; and, upon fhaking the veffel, inftead of fparks of light, the whole mafs appeared one continued circle of light. Farther, if mercury be inclofed in a glafs tube, clofe ftopped, that tube is found, on being rubbed, to give much more light, than when it had no mercury in it. When this tube has been rubbed, after raifing fucceffively its extremities, that the mercury might flow from one end to the other, one fees a light creeping in a ferpentine manner all along the tube; that is to fay, the mercury is all luminous. The mercury, being made to run along the tube afterwards

afterwards without rubbing it, was found to emit ſome light, though much leſs than before: this proves that the friction of the mercury againſt the glaſs, in running along, does in ſome meaſure electrify the glaſs, as the rubbing it with the hand does, only in a much leſs degree. This is more plainly proved by laying ſome very light down near the tube, for this will be attracted by the electricity raiſed by the running of the mercury, and will riſe to that part of the glaſs along which the mercury runs; and it is very plain from this, that what has been long known in the world under the name of the phoſphorus of the barometer is not a phoſphorus, but merely a light raiſed by electricity, the mercury electrifying the tube. Phil. Tranſ. N° 484. See Electricity and Mercury.

Phosphori, *Artificial*, are ſuch as owe their luminous quality to ſome art or preparation.

Phoſphori are, it is well known, often produced by art; ſome are made by the maceration of plants alone, and without any fire; ſuch as thread, linen cloth, but above all paper. The luminous appearance of this laſt, which is now known to be an electrical phenomenon, is greatly increaſed by heat. This is confirmed by two experiments; the firſt is, by expoſing the paper, ſpread upon an iron grate, to the naked fire, yet not near enough to reſcorch it, and then laying a warm brick thereon to retain the heat; by which means it was obſerved, that where the paper was not ſcreened by the iron grate, it was moſt luminous; ſo that by the lights and ſhades you might diſtinguiſh in the dark the image of the iron grate a conſiderable time. The other experiment is. the application of the paper to a plate of warm braſs; from which, when in the dark, you might very eaſily, by its being leſs luminous, diſtinguiſh the margin of the paper that had not been warmed by the braſs.

However Beccarius, though he acknowledges that paper, after having been made red-hot and cooled again, is an excellent phoſphorus, found, that it was much injured by being expoſed to the light of the ſun. He made experiments to the ſame purpoſe with a great variety of ſubſtances, mineral, vegetable, and animal; and obſerved, that the effects were the ſame, and that the ſtronger the light was, and the longer they were expoſed to it, the more injury they received: and he found alſo, that the injury they received was laſting.

The ſame author takes notice alſo of thoſe phoſphori which become ſo by the aſſiſtance of fire; but the fire here ſpoken of is not great enough to diſſolve their conſtituent parts, but only ſuch as may affect the external parts of their texture, and that but gently; ſo that the proceſs here mentioned is only drying or roaſting. For it is not the watery or the ſaline parts in bodies which are torrified, but the oleaginous, with which many vegetables, and moſt animals abound. The white fleſh of animals, ſuch as that of chickens, become a phoſphorus by roaſting, as well as the tendons; and whatever parts of animals become glutinous by boiling, ſuch as carpenters' glue, iſinglaſs, &c. to theſe may be added cheeſe. Bones, though they imbibe light without any preparation, have that property in a much greater degree when burnt, and their luminous appearance is much more lively. But roaſting has not this effect upon feathers, hoofs, horns, and only in a ſmall degree on whites of eggs, though the yolk when dry eaſily became a phoſphorus.

The ſame operation which produces ſeveral phoſphori from the animal kingdom, gives alſo ſeveral from the vegetable. Thus, by gently roaſting gums, as myrrh, gum tragacanth, and others, they appear luminous, though different in degrees; and this light is clear in proportion to the gentle evaporation of the aqueous parts. By this treatment nuts of every kind, pulſe, corn, coffee-berries, meal, bread, and wafers, alſo become phoſphori. Turpentine, amber, and ſome reſins, require more fire before they imbibe light; ſo that you muſt diveſt them of their acid, and their light etherial oil, to make them appear luminous. But here great care muſt be taken that they boil no longer than from being white they turn yellow; for, if you proceed longer, your labour is loſt. Thoſe phoſphori produced by torrefaction ſoon loſe their power, which, perhaps, neither time, nor a thorough diſſolution of their parts, can deprive the natural ones of. In general, as long as the phoſphori gained by torrefaction preſerve their power, their light is more ſharp and ſtriking, but the natural more weak. Thoſe that are gained by calcination, and Baldwin's phoſphorus, ſeem to poſſeſs both the ſtriking light of thoſe gained by torrefaction, and the weaker light of the natural phoſphori: the laſt they preſerve a long time, but the former is loſt, by degrees, much ſooner. The well calcined aſhes of plants, or rather their terreſtrial parts, remaining after the ſolution of their fixed ſalts by waſhing, and neutral ſalts, continue phoſphori after many years: ſo that, as far as we can judge, the luminary power which is gained by calcination, though not ſo intenſe, continues perpetual; whereas, that gained by torrefaction always decreaſes, and, in a very little while, is no longer viſible. Some, even by this method, continue to imbibe light much longer than others. Gum arabic, which continues longeſt, laſts ſix days; bread not one, and coffee only a few minutes. However, at any time, by a freſh torrefaction, you may recover theſe languid phoſphori; in which property they have great likeneſs to the Bolognian ſtone, and other phoſphori prepared by art.

Almoſt all bodies, by a proper treatment, have that power of ſhining in the dark, which, at firſt, was ſuppoſed to be the property of one, and afterward only of a few. How this is brought about is not eaſy to ſolve. If we ſuppoſe, with ſome, that the light from a luminous body enters and abides in the phoſphori; we ſhall find ſomewhat new to admire in light itſelf. It is no new opinion, that this fluid conſiſts of very fine particles, which are continually darted forth from a luminous body in all directions, with a very great velocity: but it has by nobody been laid down hitherto, that theſe particles are not diſſolved by the violence of their agitation, nor diſperſed, nor immediately ceaſe to exiſt; but ſubſiſt ſtill, and adhere to what bodies come in their way, as heat does. If, therefore, the particles of light are not diſſolved as ſoon as they are emitted from a radiant body, but continue ſome time, what elſe is required but that we allow its atmoſphere to every lucid appearance? If the phoſphori ſhine with a borrowed light, but not with their own, and that only when put in motion, and fired by the rays of a ſhining body, which ſome experiments ſeem to confirm, then other new doctrines will ariſe. There muſt be then a hidden, a ſecret principle in bodies, to be lighted up by this moſt ſubtle fire. There will be in the univerſe a certain perpetual fire from theſe phoſphori; the matter of which, though conſtantly diſſipated by burning, does not waſte enough to be obvious to our ſenſes. See Phil. Tranſ. N 478. in vol. xliv. art. 17. p. 83. and Beccarii Com. p. 52. 91, &c. See Light, Light *from Diamonds*, and *Bolognian* Phosphorus, *infra*.

Of artificial phoſphori there are three principal kinds: the firſt *burning*, which conſumes every combuſtible it touches; the other two have no ſenſible heat; and are called

called the *Bononian* and *Hermetic* phofphorus, to which clafs others of a fimilar kind may be reduced.

Phosphorus, *Burning*, in *Chemiftry*, is a fimple inflammable fubftance.

The difcovery of this phofphorus was firft made in 1677, by one Brandt, a citizen of Hamburgh, in his refearches for the philofopher's ftone. Brandt communicated the fecret to one Kraaft, of Drefden, but withheld it from Kunckel; upon which this chemift, knowing that urine was the fubftance employed, fucceeded in his attempts of making phofphorus; accordingly, this phofphorus is commonly called *Kunckel's* phofphorus, after his name. A fimilar phofphorus was alfo made by Mr. Boyle, after having feen a piece of it in the hands of Kraaft, who brought it to London in 1679, in order to fhew it to the king and queen of England; having been only informed that this phofphorus was produced from fome matter belonging to the human body. Kraaft, indeed, told Stahl, that he had communicated the procefs for making it to Mr. Boyle; but this is fuch an imputation on the integrity and honour of our Englifh philofopher, as can by no means be admitted on the teftimony of a man, who had been treacherous to Kunckel, who traded in the fecret of making phofphorus, and after felling it to many perfons, publifhed the procefs for making it in the Mercure Galont, for June 1683. Kunckel, and a German chemift called Godfreid Hantkwitz, to whom Boyle communicated the method of preparing it, were the only perfons who made it in any confiderable quantities.

M. Hellot, in his Memoir upon this fubject, Ac. Paris, 1737, enumerates all the proceffes for making it, that were in ufe foon after the difcovery of it; *viz.* that pubblifhed by Mr. Boyle in 1680, in the Phil. Tranf. N° 196. (fee Phil. Tranf. Abridg. vol. iii. p. 346.); that of Kraaft; that of Brandt, in a collection of experiments and obfervations of Dr. Hooke, publifhed by Dr. Derham in 1726; that of M. Homberg, in the Ancient Memoirs of the Academy, in 1692; and thofe found in the works of feveral chemifts, particularly of Theickmeyer, Hoffmann, and Niewentyt. However, the operation continued in a great degree a fecret till the year 1737, when a ftranger came into France, and obtained a reward from the miniftry for communicating his procefs, which was executed by Meffrs. Hellot, Du Fay, Geoffroy, and Duhamel. Since the publication of M. Hellot's Memoir, the operation has been no longer a fecret; though feldom executed, becaufe it was rather curious than ufeful, and both troublefome and expenfive.

The folid phofphorus was formerly prepared from urine in the following manner. Evaporate a good quantity of urine of beer-drinkers to the confiftence of honey; cover it up in an earthen veffel, and fet it three or four months in a cellar to ferment and putrefy. Mix two parts of fand, or powder of pot-fherds, with one part of this urine, and put it into a retort, fitted to a long-necked receiver, with two or three quarts of water in it. Diftil it in a naked fire, in a reverberatory furnace; at firft gently; after two hours, augment the fire gradually, till all the black fetid oil be drawn off. Raife the fire to the higheft degree; upon which white clouds will come into the receiver, and fix, by little and little, on one fide, in form of a yellowifh fkin; and another part will precipitate to the bottom in powder. Keep the fire thus violent for three hours, till no more fumes arife. Let all cool, and unloofe the veffels; and, throwing more water into the receiver, fhake all well about, to loofen what fticks to the fides. Pour the whole into a glafs veffel, to fettle.

The volatile falt will now diffolve in the water, and the phofphorus and oil will fink to the bottom; then pour off the water, and gathering the remaining part together, put it into a glafs veffel, with a little frefh water, and digeft it in a fand-heat, ftirring it from time to time with a wooden fpatula.

By this means, the phofphorus will feparate from the oil, and fink to the bottom: pour off the oil, and make up the phofphorus, while hot, into fticks for ufe.

Boerhaave gives us other ways of preparing phofphorus. Recent urine, he obferves, digefted three or four days in a tall glafs, with a heat no greater than that of a healthy man, grows ruddy, fetid, and cadaverous; this digefted urine, being put to diftil in a retort, yields a clear, fetid liquor, then a yellow volatile falt, which evaporated to the confiftence of a fapo, and mixed with four times its weight of dry fand, and the diftillation continued in a covered retort, there fucceffively comes over, by greater and greater degrees of fire, a fetid brown oil, blueifh fumes, and, finally, a grofs fhining matter, which finks in water, and is the folid phofphorus.

To make it more eafily, and to the beft advantage, it may be proper to take a fufficient quantity of human urine, afforded by a perfon not much given to drink wine, and exhale it away in an open veffel to a rob, or the confiftence of honey; then fet it to putrefy for half a year, and, upon diftillation, it will afford a large proportion of falt, after which, if fix times its own quantity of fand, or brick duft, be added to the remainder, and the diftillation be continued, as in the cafe laft mentioned, the phofphorus will fall into the water. Or it may commodioufly be prepared, by fuffering the rob of urine to digeft for two years in an open veffel in the open air; during which time, a flimy, feculent, unctuous, earthy matter, will fall to the bottom; which, being frequently wafhed with pure water, wherein it will not diffolve, will leave a white matter behind it, neither of an alkaline, acid, faline, or terreftrial, nor fcarcely of an unctuous nature: and this is of itfelf a proper matter for the making of phofphorus by diftillation with fand.

In order to preparing the phofphorus, and indeed moft of the other preparations of urine, the firft ftep is to reduce that liquor to the confiftence of a rob or thick extract; thofe who have worked on this fubject fufficiently know how abominably naufeous and difagreeable a tafk this is. The operator alone is not the perfon who is almoft poifoned by it, but the whole neighbourhood is affected; and it is well known, that our Godfrey, who ufed to prepare large quantities of this fubftance, was always obliged to keep a houfe in the fields to perform this part of the procefs in.

There is an eafy and excellent method propofed by Stahl for the performing of this troublefome bufinefs, by means of condenfation by cold or freezing. There needs no more than to expofe the proper quantity of urine to fome frofty nights in winter; or at any time of the year to our icehoufes, or other places where ice is preferved all the year round. The froft will, in this cafe, affect a large part of the urine, but not the whole; and the liquid part being feparated from the folid ice, it will be found that the watery parts alone have fuffered the freezing, and that all the unctuous and faline ones are left behind in the unfrozen part, which is, by repeated freezings of its yet remaining aqueous parts, at length reduced to that fort of rob which is required for all the purpofes of diftillation, and that without any trouble or offenfivenefs, either to the operator or any body elfe. The power of condenfation by freezing in this manner, extends to wine, vinegar, and all fermented liquors;

liquors; but it operates differently on the feveral different ones, and is to be regulated according to their natures. The natural cold of our climate is feldom too great for any of the liquors we defire to condenfe; that is, it is never fo great as to condenfe the whole into ice. It often is not fufficiently great to condenfe the aqueous part, even after ever fo many repetitions. In this cafe, it may be proper to bring in the ufe of the common freezing mixtures, made with ice, or fnow and falt. To fuit the artificial degree of cold, in thefe cafes, requires care and experience, and is almoft as nice a point as the fuiting of the degrees of heat in the operations of chemiftry.

In 1743, Mr. Margraaf publifhed, in the Memoirs of the Academy at Berlin, a new and excellent procefs for obtaining more eafily and expeditioufly, and at lefs expence than had hitherto been done, a confiderable quantity of phofphorus. In his procefs, a kind of plumbum corneum is previoufly prepared, by diftilling a mixture of four pounds of minium with two pounds of powdered fal ammoniac; the refiduum after the diftillation, or the plumbum corneum, is to be mixed with nine or ten pounds of extract of putrefied urine, boiled to the confiftence of honey. This mixture is to be made flowly in an iron cauldron fet upon the fire, and by frequently ftirring the contents. Half a pound of powdered charcoal is then to be added, and evaporation is to be continued till the whole is reduced into a black powder, which is to be put into a retort, in order to extract from it, by a moderate and gradual heat, all the volatile products of urine, that is, volatile alkali, fetid oil, and an ammoniacal matter which adheres to the neck of the retort. In this diftillation the heat is only to be raifed fo as to make the matter red-hot. After the diftillation a black and friable refiduum is left, from which the phofphorus is to be extracted by a fecond diftillation, and a ftronger heat. Before it is expofed to another diftillation it may be tried by throwing fome of it upon hot coals. If the matter has been well prepared, a fmell of garlic exhales from it, and a blue phofphorical flame is feen undulating along the furface of the hot coals. This matter is to be put into a good earthen retort, capable of fuftaining a violent fire, and which may be fecured with a covering of clay and hair. Three quarters of the retort are to be filled with the matter which is to yield the phofphorus. It is to be placed in the common furnace for diftillation with a retort; excepting that inftead of being terminated by an ordinary reverberatory or dome, this ought to be terminated by the upper piece of an air-furnace, to which a tube is to be applied, the diameter of which ought to be from four to fix inches, according to the fize of the furnace, and the height from eight to nine feet. This apparatus, which Mr. Beaumé ufes, is neceffary for raifing a fufficient heat, and for the convenience of throwing in a fufficient quantity of fuel through the door of the upper piece of the furnace. The retort ought to be well luted to a receiver of moderate fize, pierced with a fmall hole, and half full of water. For this purpofe ordinary fat lute may be bound on with ftrips of linen, dipped in a lute prepared with lime and whites of eggs. The hole in the furnace through which the neck of the retort paffes ought to be well ftopped with furnace-earth. Laftly, a fmall wall of bricks is raifed betwixt the furnace and the receiver, to guard this veffel againft heat as much as is poffible.

All thefe preparations being made the evening before the diftillation is to be performed, we are then capable of proceeding to this operation, which is very eafy. The retort is to be heated by flow degrees during an hour and a half; and then the heat is to be increafed till the retort be red-hot, and the phofphorus begin to pafs in luminous vapours: when the retort is almoft of a white-red heat, the phofphorus paffes in drops, which fall and congeal in the water at the bottom of the receiver. This degree of heat is continued till no more paffes into the receiver. When a retort contains eight pints or more, this operation continues about five hours.

Mr. Margraaf's apparatus is fomewhat different from that above defcribed. He divides the whole quantity of matter from which the phofphorus is to be obtained into fix fmall retorts, which he places in a furnace that he defcribes. The advantage of this divifion is, that if any accident happens to one retort, the whole matter is not loft; and as the retorts are fmaller, a lefs heat is required. If, indeed, much phofphorus was to be made, this practice would be fafe and excellent; but Macquer affirms, that the method above defcribed of Mr. Beaumé is very convenient when a large quantity of phofphorus is not wanted, and that he has never feen it fail.

Phofphorus does not pafs pure in this diftillation, but is blackened by foot or coal, which it carries along with it: it may be eafily purified, and rendered white and fine by a fecond diftillation or rectification. This rectification is made in a fmall glafs retort, to which is adjufted a fmall receiver half full of water. A very gentle heat is fufficient, becaufe phofphorus once formed is very volatile: and as the fuliginous matters with which it is foiled were raifed merely by the violence of the heat, they remain at the bottom of the retort in this diftillation, and the phofphorus paffes very pure.

The phofphorus is then ufually divided into fmall cylindrical rolls, for the conveniency of ufing it. This is done by putting it in glafs tubes immerfed in warm water. This very gentle heat is fufficient to liquefy the phofphorus, which is almoft as fufible as fuet. It takes the form of the glafs tubes, from which it may be taken out when it is cold and hardened. That it may be more eafily taken out of the tubes, thefe muft be fomewhat of the form of fruftums of cones. All thefe operations ought to be made under water, to prevent the inflammation of the phofphorus.

Phofphorus is now ufually procured by the following procefs. Calcine a quantity of bones till the whole of their inflammable matter is confumed, which will be indicated by their whitenefs. After they are reduced to a fine powder, let 100 parts, by weight, be mixed with 500 parts of water, in a veffel of ftone ware, or any other which fulphuric acid will not act upon. To the above mixture add, by degrees, 40 parts of fulphuric acid, conftantly ftirring the mixture with a ftick or a glafs rod. After the effervefcence has fubfided, let the mixture ftand for a day or two, then decant off the clear liquor, which is to be preferved. Let the refiduum be agitated with a quantity of frefh water, and thrown upon a filtre, adding the clear liquor which runs through to that decanted in the firft inftance. Let more water be poured upon the filtre till it comes through taftelefs. This being added to the laft, the whole will contain a fuper-phofphat of lime, with great excefs of acid. In order to feparate the phofphoric acid from the lime, the nitrat of lead is to be added. Phofphat of lead precipitates in the ftate of white powder, while the lime is diffolved in the nitric acid. The phofphat of lead being very ponderous, may be feparated by decantation and repeated wafhing. When the powder is dried, mix it with one-eighth its weight of charcoal powder, and put it into an earthen retort. The common earthen retorts are feldom fitted for this procefs, being very liable to crack. The clay of which they are formed fhould be mixed with coarfely powdered crucibles, to render the texture of the fubftance when baked more open. The outfide muft be coated with white lead and flint, to form a glazing during the diftillation of the phofphorus. Without this precaution the vapour of the phofphorus would efcape through the pores of the veffel. The retort, with its contents, muft be placed in an air-furnace, with a flit in the fide to admit the neck of the retort. The fuel fhould be well burnt coaks, and the fire raifed very gradually. The neck of the retort fhould be luted to an adopter, which is fitted to a glafs receiver, previoufly filled with azotic gas. A fmall tube fhould proceed from another opening in the receiver, terminating in a pneumatic trough. This ferves to carry off the elaftic fluids which are difengaged in the procefs. During the firft ftage of the procefs carbonic acid is difengaged, which is afforded by the carbon combining with the oxygen of the phofphoric acid and the oxyd of lead. The charcoal always contains a portion of moifture, which is decompofed by the carbon. In the laft ftage of the procefs, when the phofphorus rifes in the elaftic form, a portion of it combines with the hydrogen of the water, forming phofphoretted hydrogen gas, which takes fire when it comes in contact with oxygen of the atmofphere. This fpontaneous inflammation of the efcaping bubbles, is a certain fign that the phofphorus is coming over. It is feen running down the adopter into the receiver, which contains a fmall portion of water for it to drop into. The mafs which drops into the water is generally of a brownifh, and fometimes a darker colour, and confifts of phofphorus, containing fome carbon, and is otherwife impure. When the apparatus is quite cold, it may be taken out, and placed in a glafs funnel provided with a long cylindrical neck, about one-fourth of an inch in diameter, clofed at one end with a cork. It is firft filled with cold water, fo as to cover the phofphorus. The whole is now immerfed into hot water, which melts the phofphorus which is caufed to occupy the interior of the tube, affuming a pale yellow colour, while that in the top part of the tube is of a darker colour, and contains the impurities. The pure part is broken into pieces, in which ftate it is fold. If the phofphorus after diftillation be very impure, it fhould be diftilled a fecond time from a glafs retort, obferving the fame precautions in the receiver as in the firft procefs. After this it may be ftrained through chamois leather under hot water.

The phofphat of lead may alfo be procured by adding nitrat of lead to urine. The latter fubftance contains a quantity of the phofphats of foda and ammonia, each of which give up their acid to the lead, forming phofphat of lead, which falls to the bottom of the veffel in the ftate of an infoluble white powder. This is doubtlefs the cheapeft way of getting phofphorus.

Stahl fuppofed phofphorus to be a compound of muriatic acid with phlogifton; but it was afterwards proved by the refearches of Margraaf, that muriatic acid could not be produced by burning phofphorus, nor could he fucceed in forming phofphorus by treating muriatic acid with inflammable bodies. He found in the courfe of his experiments, what has fince led to the overthrow of the phlogiftic doctrine. The phofphorus gained weight by burning, and he called the fubftance refulting from the combuftion phofphoric acid. Lavoifier, in a fatisfactory manner, confirmed the facts of the above chemift, by burning phofphorus in oxygen gas. The diminution of the oxygen he found juft equal to the increafe of weight in the phofphorus after burning. Hence it was eftablifhed, that phofphoric acid was a compound of phofphorus and oxygen.

Phofphorus, when perfectly pure, is of a pale yellow colour, having fome refemblance to white wax. Like the latter fubftance it foftens by heat, and is fo ductile as to be cut with a knife.

It is called "phofphorus fulgurans" from its corrufcations; and "phofphorus fmaragdinus," becaufe its light is frequently green or blue, efpecially in places that are not very dark.

It is alfo called "folid phofphorus," from its confiftence.

It diffolves in all kinds of diftilled oils; and, in that ftate, is called the "liquid phofphorus."

It may be ground in all kinds of fat pomatums; in which cafe it makes a luminous unguent.

So that the phofphorus fulgurans, fmaragdinus, folid and liquid phofphorus, and luminous unguent, are all the fame preparation, under different circumftances. See FULGURATING *Phofphorus*.

The fpecific gravity of phofphorus is about 1.77; the fufing point is 90° Fahr.; and it affumes the form of vapour at a little fhort of 600°.

When phofphorus is heated to 148 in the open air, it takes fire and burns with great brilliancy, owing to the rapidity with which it combines with oxygen. Very denfe white fumes are produced, fo as ultimately to nearly obfcure the flame. If the combuftion be made in a veffel, the fumes adhere to its fides, and become liquid, by attracting moifture from the atmofphere. A portion of red matter is left after the burning has ceafed, which is probably a compound of phofphorus and carbon. The liquid which is formed upon the fides of the veffel has an acid tafte, and confifts of phofphoric acid, water, and probably a fmall quantity of phofphorus which has efcaped combuftion. When phofphorus is burnt in pure oxygen, the light produced is of fuch dazzling fplendour as to give pain to the eyes. The combuftion is by this means complete, and if the oxygen is in fufficient quantity, the whole is converted into phofphoric acid.

Lavoifier found that 100 grains of phofphorus took up 154 grains of oxygen, fuppofing the atom of oxygen to be 7, hydrogen being 1, agreeably to the numbers of Dalton. And confidering the phofphoric acid as an atom of phofphorus with two atoms of oxygen, we have $\frac{154}{100} = \frac{14}{9.1}$. Dalton has fixed the atom of phofphorus at 9. From thefe data the atom of phofphoric acid will be $9 + 2 \times 7 = 23$.

When phofphorus is expofed to the air in fmall bits, it gives out a white fmoke for fome time, and is ultimately changed into a clear vivid oily liquid, which has an acid tafte. In this procefs it combines flowly with oxygen, and confifts of one atom of phofphorus with one of oxygen, or $9 + 7 = 16$. When phofphorus is made to undergo flight combuftion, by melting it over the interior of a phial, with the prefence of fmall quantities of air, the phofphorus affumes a reddifh colour. By this change it is found to take fire with much greater facility, fo much fo that this procefs is reforted to in the conftruction of the common fire bottles.

From this and other facts it is probable that an oxyd of phofphorus exifts with lefs oxygen than is contained in phofphorous acid. It doubtlefs is conftituted by 2 atoms of phofphorus to 1 of oxygen, or $2 \times 9 + 7 = 25$. See PHOSPHOROUS and PHOSPHORIC *Acids*.

The action of the acids upon phofphorus is treated under the refpective acids, but what has been omitted under OXYMURIATIC *Acid*, we fhall introduce here.

The muriatic acid does not act upon phofphorus when the acid is in the gafeous form, but when prefented in combination with fome other bodies, it forms very curious combinations, which have been little noticed. We are indebted

indebted to sir Humphry Davy for our knowledge of these facts.

When phosphorus is immersed in oxymuriatic acid gas, it burns with a pale flame, producing a white substance, which adheres to the sides of the vessel. The above chemist found that one grain absorbed nine cubic inches of the gas, and hence concludes that 1 of phosphorus combines with 6.8 of oxymuriatic acid, or, agreeably to the nomenclature of this philosopher, who considers the latter a simple body, *chlorine*. The number he gives to represent one proportion of chlorine is 67, that of oxygen being 15 and phosphorus 20; so that he concludes the compound formed by burning phosphorus in chlorine gas to consist of two proportions of chlorine equal 134, to one proportion of phosphorus equal to 20, or $134 + 20 = 154$, the number representing the compound. To this substance he has given the name of phosphorana. The advocates of the old hypothesis consider this compound as constituted by two atoms of muriatic acid, free from water, united to one atom of phosphoric acid, and agreeably to the common nomenclature it will be called a supermuriat of phosphorus. Dalton's number for muriatic acid is 22, for oxygen 7, and for phosphorus 9. Hence this substance will be constituted by $2 \times 22 + 2 \times 7 + 9$, or 58 oxymuriatic acid to 9 of phosphorus, but in fact 44 muriatic acid to 23 phosphoric acid.

The compound in question is described by its discoverer as being a snowy white substance. It is volatile at a temperature less than that of boiling water. It is capable of being fused under pressure, and then crystallizes in the shape of prisms which are transparent.

He states that "it acts violently upon water, which it decomposes." Its phosphorus combines with the oxygen, producing phosphoric acid, and its chlorine with the hydrogen, forming muriatic acid. The advocates for the old opinion equally well explained the action of water upon this substance, by supposing the same quantity of water to combine with the muriatic acid, which sir Humphry would state to be decomposed.

Another compound of this kind has been discovered by the same chemist, by distilling phosphorus through the powder of corrosive sublimate in a glass tube. A limpid fluid is obtained, which he states to be a compound of one proportion of chlorine with one proportion of phosphorus, or $67 + 20 = 87$. The properties of this compound are stated by sir Humphry as follows: it emits and fumes when exposed to the air, decomposing the aqueous vapour, and is converted into acid in the air without inflammation. In its pure state it does not redden dry litmus paper. The vapour from it burns in the flame of a candle. When poured into water, it is converted into muriatic and phosphorous acid, the hydrogen combining with the chlorine to form muriatic acid, and the oxygen with phosphorus forming phosphorous acid. This solution, being evaporated to the consistence of syrup, affords a very pure phosphorous acid combined with water, the muriatic acid having escaped. It becomes solid on cooling.

Sir H. Davy has called the above compound phosphorana.

By those of the common opinion, this substance is considered as a compound of pure muriatic acid and phosphorous acid. The phosphorus, on passing through the superoxymuriat of mercury, took an atom of phosphorus from the mercury forming phosphorous acid, which, combining with an atom of muriatic acid, formed the compound in question, leaving behind an atom of muriat of mercury (calomel), which consists of an atom of muriatic acid, with an atom of the first oxyd of mercury. By Dalton's numbers this substance is constituted by one atom of muriatic acid, 22 added to one of phosphorous acid, equal to $9 + 7$ or 16, the whole being equal to $22 + 16 = 38$. All the phenomena stated above, which have been explained by sir Humphry's hypothesis, will be equally well explained by the old theory. The above ingenious chemist has pointed out a third compound of chlorine with phosphorus, which he supposes to consist of one proportion of chlorine with two of phosphorus, or $67 + 2 \times 20 = 107$. This, by the old doctrine, would be considered as composed of 1 of muriatic acid, 22 to 2 of phosphoric oxyd, equal 32, the whole being 52.

This substance was first obtained by Guy Lussac and Thenard, by distilling phosphorus and calomel. If its constitution be as above stated, 9 of phosphorus should be distilled with 196 of calomel.

Phosphorus combines with hydrogen, forming a gaseous compound called by some phosphoretted hydrogen, and by others more properly phosphoret of hydrogen. Several circumstances shew the affinity between phosphorus and hydrogen to be very slight, particularly its liability to be decomposed even by agitation with water. The following is the process recommended by Dalton for procuring it. To two ounces of dry hydrat of lime, or lime which has just taken as much water as is required to slack it, add 50 grains of phosphorus in small bits. Let these be put into a glass retort, which has been previously filled with nitrogen gas. Without the latter precaution the presence of oxygen would decompose the gas intended to be obtained. Let the neck of the retort be connected with an hydromuriatic trough, and apply the heat of a lamp, which brings over the gas. The lime is here more than is necessary, which is no inconvenience. The absolute quantities which are engaged in the process are, 1 atom of hydrat of lime $= 8 + 24$, and 2 atoms of phosphorus $= 2 \times 9 = 18$. The water of the hydrat of lime is decomposed. The oxygen combines with one atom of phosphorus, forming phosphorous acid, which afterwards combines with the lime. The hydrogen combines with the other atom of phosphorus, forming phosphoret of hydrogen, which comes over in the form of gas. In this state it takes fire spontaneously in the open air, or in contact with oxygen. The phosphorus is easily separated by the electric spark, and even by standing over water, leaving the hydrogen pure, and occupying the original volume of the gas. This latter effect taking place partially, has given rise to the opinion of phosphorus combining with hydrogen in different proportions. We can hence explain the assertion made by sir H. Davy, in which he says he has obtained phosphoretted hydrogen gases of different specific gravities, from 4 to 7; hydrogen being 1.

The composition of this gas is easily inferred from its specific gravity, which Dalton states to be 10.5, hydrogen being 1. Hence if 1 of hydrogen takes up 9.5 of phosphorus without any change of volume, it will make the specific gravity as above. By theory, 9 of phosphorus should combine with 1 of hydrogen, when 1 atom of the former combines with 1 of the latter. We may hence conclude that an atom of this gas in a state of purity is $1 + 9 = 10$.

To confirm this, Mr. Dalton found that 1 measure of this gas to 1.5 oxygen produced phosphoric acid; and 1 measure to 1 produces phosphorous acid. We are indebted to sir Humphry Davy for the discovery of a new compound of phosphorus and hydrogen, which he obtained by exposing the solid hydrat of phosphorous acid to heat in a retort. An elastic fluid is produced, having a less disagreeable smell than the phosphoret of hydrogen, already described. It does not, like the latter, explode spontaneously. When heated to 300° Fahrenheit with oxygen, it detonates with violence,

violence. It alfo explodes in oxymuriatic gas with a white flame. This chemift fuppofes its fpecific gravity to be about 12, hydrogen being 1.

When heated in potaffium, its volume is doubled, and the gas produced is pure hydrogen. When fulphur is fublimed in it, the volume is doubled, and fulphuretted hydrogen gas produced.

He found that 3 in volume of this gas took up more than 5 of oxygen. He concludes its compofition to be nearly 2 of hydrogen to 10 of phofphorus, by weight. According to Dalton's numbers it will confift of an atom of phofphorus to 2 of hydrogen, or $9 + 2 = 11$. If its volume be doubled by taking away its phofphorus, which is the cafe in the experiment with potaffium, its fpecific gravity will be increafed by 1 compreffed into $\frac{1}{2}$, which will give a fpecific gravity equal to 2: this added to 9, the weight of the phofphorus, will give $9 + 2 = 11$, which is very near to fir Humphry's experiment. In the experiment where it combines with the fublimed fulphur, the volume is doubled, and two atoms of fulphuretted hydrogen are formed, one of which being equal to the original volume, will make the fpecific gravity of this gas equal to that of fulphuretted hydrogen, which is about 14, hydrogen being 1. The mean of thefe will be $\frac{11 + 14}{2} = 12.5$, which comes very near to fir Humphry's ftatement of the fpecific gravity, and ftrongly confirms the reft of the facts relative to it.

The oxygen required for its total abforption will be 28 to 11 by weight, and $\frac{28}{11} \times \frac{12}{14} = \frac{24}{11}$, or 2 to 1 by meafure nearly. This is obtained by multiplying their ratios of weight by the inverted ratio of their fpecific gravities.

Phofphorus combines with fulphur by melting them together in a glafs tube, from which oxygen is excluded. The compound is more fufible than either of the elements. Sir Humphry Davy found that a compound of thefe bodies in the proportion of 3 of fulphur to 4 of phofphorus, is fufible at 40° Fahrenheit. When folid, its colour was of a yellowifh-white. Thefe bodies, like all others, muft produce moft complete compounds in certain definite proportions dependent on the ratio of the weight of their ultimate atoms. Atom to atom, their proportions will be 9 to 13. The compound above alluded to will be 2 atoms of phofphorus to 1 of fulphur, or $18 + 13 = 31$. The moft remarkable properties poffeffed by thefe compounds are their increafed fufibility, and their taking fire at a lower temperature than phofphorus. This latter property has been taken advantage of in making the common fire-bottles. Their proportions for this purpofe are generally about 2 phofphorus and 1 fulphur. This is nearly 3 atoms of phofphorus to 1 of fulphur, which would be 3×9 to $13 = 27$ to 13.

Dr. Prieftley has made many experiments with phofphorus, in different kinds of air; and has found, that it fmoked and gave light in the acid air, juft as it would have done in common air confined, without being fenfibly wafted for twelve hours, and with a very inconfiderable diminution of the bulk of the air; in alkaline air it gave no light and made no lafting change in its dimenfions; in nitrous air, it gave no light, nor did it leffen its power by diminifhing common air, and the phofphorus remained unchanged; and after having remained a day and two nights in vitriolic acid air, it produced no fenfible effect, and gave no light.

Dr. Fordyce has fuggefted the following eafy method of reducing phofphorus to powder: take phofphorus of urine two drachms; put it into a four-ounce phial; pour upon it three ounces of water; heat it gently by immerfion in warm water, till the phofphorus melts; fhut the phial with a cork; take it out of the water, and fhake it brifkly till it be cold; and the phofphorus will be found in powder. A receiver may be lined with this powder by adding a very fmall quantity of water to it, and then making the powder to adhere to its internal furface, by gently inclining and turning the receiver round. Macquer's Chem. Dict. art. *Phofphorus*, and Prieftley's Experiments and Obfervations on Air, &c. Phil. Tranf. vol. lxi. part ii. p. 504, &c.

Phosphorus, *Properties of Solid.* 1. With this phofphorus one may write on paper as with a pencil, and the letters will appear like flame in the dark; yet, in the light, nothing will appear but a dim fmoke. This is occafioned by the oxygen of the atmofphere combining flowly with the phofphorus.

If the letters written with this phofphorus are warmed by the fire, they prefently become dark lines, which continue upon the paper like ink.

2. A little piece, rubbed between two papers, takes fire inftantaneoufly, and if care be not taken in the management of it, there is danger of burning the fingers, the phofphorus being exceedingly inflammable.

3. Its burning is very vehement, and penetrates deeper into the flefh than common fire; and it is very difficult to be extinguifhed.

Dr. Slare, in order to determine whether air contains the pabulum of flame, as fome have fuppofed, placed a large piece of phofphorus in a receiver; but upon exhaufting it, he found that it became more luminous, and that upon admitting the air it returned to its former ftate. This property was alfo afcertained by feveral experiments of Mr. Haukfbee.

M. Caffini happening to prefs a piece in a cloth between his fingers, the cloth immediately took fire; he endeavoured to put it out with his foot; but his fhoe caught the flame, and he was obliged to extinguifh it with a brafs ruler, which caft forth rays in the dark for two months after.

The folid phofphorus ceafes to fhine and never fpoils, provided it be kept in a phial full of water; but if any part of it emerge, it will fhine, though the glafs be hermetically fealed; and will continue fhining in a large glafs without water for feveral days, with very little diminution of its light or weight; and even when immerfed in water, it will fometimes make very bright and vigorous corrufcations in the air; that in form of an unguent, does not keep fo well; and the liquid phofphorus worft of all.

The liquid phofphorus is beft made by digefting in horfedung, a little bit, or fome fcrapings of the folid kind, for two days, in oil or effence of cloves, oil of turpentine, or the like. After the diffolution, the oil will be fo impregnated with it, that, upon opening the bottle, the matter will appear on a flame.

Phosphorus, *Experiments with Liquid.* By wafhing the face, hands, or the like, with liquid phofphorus, Dr. Slare tells us they will be made to fhine very confiderably in the dark, and the luftre thereof will be communicated to adjacent objects, yet without any offence to the fkin.

As foon as the candle is brought in, the fhining difappears, and no change is perceiveable.

This phofphorus emits frequent flafhes like lightning, even when clofe ftopped, efpecially in warm water. Hence Mr. Boyle takes occafion to draw a parallel between lightning and phofphorus. Phil. Tranf. Abr. vol. iii. p. 348, &c. Haukfbee's Phyfico Mech. Exper. p. 122. In fome cafes animal fweat, which is fimilar to urine, has been obferved to be phofphoraceous, without any preparation. An inftance of this kind is related of a perfon who ufed to eat great quantities of falt, and who was a little fubject to the gout, after fweating with violent exercife. Stripping himfelf in the

the dark, his ſhirt ſeemed to be on fire, and a urinous ſmell was perceived, ſimilar to that which iſſues from cabbage much ſalted and ſtrongly fermenting. Act. Cæſarienſia, vol. v. p. 334.

Phosphorus, *Bolognian*, or *Bononian*. The ſecond kind of artificial phoſphorus, is a preparation of ſtone called the Bononian ſtone, from Bologna, a city in Italy, near which it is found.

The firſt who undertook to make this ſtone luminous, was a chemiſt of that city, called Vicenzo Caſciarolo. Poterus, Licetus, &c. have deſcribed the proceſs; but miſtakenly. M. Homberg, who made a journey to Italy, expreſsly to learn the preparation, firſt communicated the ſame to M. Lemery, who publiſhed it in the ſeventh edition of his chemiſtry. (See Bononian *Stone*.) Under that article, the reader will find ſome account of the diſcovery of this ſtone, and of the method of preparing it. We ſhall here ſubjoin ſome farther particulars on this ſubject, chiefly extracted from the diſſertations of M. Margraaf. The Bolognian ſtone, he ſays, is ſoft, friable, heavy, cryſtallized, and incapable of effervefcing with acids, before it has been calcined in contact with fuel, and with a free acceſs of air. Theſe qualities have induced him to claſs it among the heavy fuſible ſpars, which, by a preparation ſimilar to that for the Bolognian ſtone, are rendered phoſphoric. After analyſing theſe ſubſtances, he concludes that all contain a vitriolic acid, united to an alkaline or calcareous earth. In order to render theſe ſtones phoſphoric, ſuch of them ought to be choſen as are the cleareſt, but cryſtallized, moſt friable, moſt heavy, which exfoliate when broken, and which contain no heterogeneous parts. They are to be made red-hot in a crucible, and reduced to a very fine powder in a glaſs mortar, or upon a porphyry, and not in a copper mortar, which will obſtruct the ſucceſs of the operation. The powder thus obtained, is to be formed into a paſte with gum tragacanth, and divided into cakes as thin as a knife. Theſe are to be dried by a gradual heat. An ordinary reverberatory furnace is to be filled to three quarters of its height with charcoal, and the fire to be kindled; upon this charcoal the flat ſurfaces of the cakes are to reſt; and more charcoal is to be placed above them, ſo as to fill the furnace, which is then to be covered with its dome, the tube remaining open: all the coal is to be conſumed, and the furnace left to cool. The cakes are then calcined, and are to be cleanſed from the aſhes by blowing upon them with bellows. He farther obſerves, that after this calcination through the coals, if the ſtones be expoſed to a ſtronger calcination during a full half hour under a muffle, their phoſphoric quality will be rendered ſtronger. Ac. Berlin, 1749, and 1750.

This phoſphorus has not any ſenſible heat, and only becomes luminous after being expoſed to the ſun, or the daylight; in which ſtate it reſembles a burning coal, and preſerves its light five or ſix minutes in the dark, eſpecially if the perſon obſerving it has been ſome time in the dark, or has ſhut his eyes, that the pupils may be ſufficiently expanded; during which time the light gradually dwindles; and, to recover the ſhining, it muſt be expoſed afreſh to the light.

Phosphorus, *the Hermetic*, or *Phoſphorus Balduini*, which makes the third kind, and properly belonging to the ſame claſs with the former, is a preparation of Engliſh chalk, with aquafortis, or ſpirit of nitre, by the fire. See Baldwin's *Phoſphorus*.

This makes a body conſiderably ſofter than the Bolognian ſtone; but it has all the qualities of it. It has its name from its inventor Baldwin, a German chemiſt, called *Hermes*, in the ſociety of the Naturæ Curioſorum; whence its other name *Hermetic*. It was diſcovered a little before the year 1677.

This phoſphorus of Baldwin is exactly ſimilar to thoſe made with Bolognian ſtone and phoſphoric ſpars, differing only in the kind of acid which it contains. It is evidently a nitre with a calcareous baſis, and in calcination acquires its phlogiſton from the nitrous acid, the chalk alſo containing ſome of this inflammable principle. It is obſerved, however, that this is not ſo good a phoſphorus as the Bolognian; it is not ſo luminous, it does not retain the light ſo long, it ſoon loſes its virtue, and never recovers it again. Acad. Par. 1693, p. 271.

The proceſs for making this phoſphorus, though Baldwin gave no direction for it, nor ſo much as mentioned the materials, was communicated to the Royal Society, in 1679, by Dr. Slare, and publiſhed by Grew, in his Muſ. Reg. Soc. p. 353; and is as follows: Take good firm chalk, ignite it in a crucible, and then powder it; put into a pint, or half a pint of ſtrong ſpirit of nitre, *cochleatim*, as much of the powdered chalk as will ſerve well to ſatiate it, *i. e.* till it becomes ſweetiſh, and makes no efferveſcence upon the injection of the chalk. Then dilute this liquor with fair water, filtre it through a paper, and ſo evaporate it in a large glaſs, or glazed veſſel, or good Heſſian crucible, to a dry ſalt. The preparation may be performed in four hours.

To this claſs we may alſo refer ſome other phoſphori, enumerated in the ſequel of this article. As the

Phosphorus, *Ammoniacal*, compoſed of ſal ammoniac and lime, which Mr. Homberg firſt diſcovered.

The method of preparing it is this: Take one part of ſal ammoniac in powder, and two parts of lime extinguiſhed by lying in the air: mix them exactly together and fill a crucible with the mixture; ſet it in a ſmall melting heat. As ſoon as the crucible grows red-hot, the matter in it will melt, and it muſt be ſtirred with an iron rod, leſt it ſwell over the edges of the crucible: as ſoon as the whole is melted, pour it into a copper baſon; it will appear of a greyiſh colour and vitrified, and if it be ſtruck upon with any hard body, there will be ſeen a fire all over the place where the blow was given. As this matter is brittle, however, and the ſame maſs will not ſerve often for the experiment, the beſt method is to dip iron rods in it while melting, and theſe will be covered with the matter, and will anſwer the purpoſe eaſily and often. Mem. Acad. Par. 1693.

This is a combination of quick-lime with the acid of ſal ammoniac.

Phosphorus, *Antimonial*, is the name of a ſubſtance having the qualities of the phoſphorus diſcovered by Mr. Geoffroy, in his experiments on antimony. This gentleman had prepared a ſoap from pot-aſhes, quick-lime, and oil, with which he made ſeveral experiments on antimony; among others, he was deſirous, by means of this, to reduce ſome diaphoretic antimony, which he had before made from two parts of the regulus of antimony, and three parts of nitre; but, inſtead of the reduction which he was labouring after, his operation afforded him a much more ſingular phenomenon: the reſult of them being a phoſphorus, which he had never thought of; a matter which, after having remained perfectly quiet while cloſe ſtopt down, took fire as ſoon as ever it was expoſed to the air; and that with a violent detonation, and darting every where a ſhower of fire.

It is eaſy to ſee, that there are in the preparation all the requiſites for ſuch an effect; nitre, charcoal furniſhed by the burnt ſoap, and ſulphur both from the ſoap and from the regulus of antimony; and to all theſe a ſort of calx, either

either from the ſoap, or from ſome earthy parts of the antimony. It is eaſy to conceive, that all theſe ſubſtances, coming into a mixture together, ſhould be ready to catch fire and blaze, upon a proper application; but it is not leſs difficult to account for the effects being produced merely by the air, after the whole had been for a long time in a ſtate of reſt.

The method of preparing this new ſpecies of phoſphorus is this: Mr. Geoffroy mixed two ounces of his ſoap with one ounce of this diaphoretic antimony; this mixture, being put by little and little into a red-hot crucible, took fire, and ſwelled very much; after it had done flaming, the maſs ſubſided, and became a red or fire-coloured ſubſtance, of an even ſurface, but ſtill throwing up a vaſt quantity of blueiſh-green luminous vapours; and all this regularly happened on every freſh throwing in of the matter, without the leaſt variety. When the whole quantity was thrown in, and had ceaſed to give any flame or luminous vapour, it remained in the crucible in the form of an inverted muſhroom, being hollow, very porous, and of a black colour. When the crucible was taken out of the fire, the edges of this ſubſtance were beaten down into the middle, and the whole covered with an ounce of freſh ſoap; when this laſt ſoap was burnt, and a ſmall blueiſh flame appeared upon the ſurface of the maſs, the crucible was covered with a lid, and a large quantity of charcoal laid upon it, and the fire blowed up very briſkly by an hundred blaſts of the bellows, or thereabouts; but, notwithſtanding the fierceneſs of the fire, there was no fluid ſcoria formed, but the whole maſs remained ſpungy and porous; the fire was then ſuffered to go out, and the crucible placed in the corner of the elaboratory at reſt for five hours. In the evening, when the crucible was perfectly cold, Mr. Geoffroy went to examine the matter, and a ſervant went to uncover the maſs, by removing its ſurface with an iron inſtrument; but the moment the air was admitted, the whole maſs took fire, burning with a very conſiderable noiſe, and darting its flames every way to a great diſtance.

Mr. Geoffroy repeated the proceſs ſeveral times, and always with the ſame ſucceſs, whether he uſed his own diaphoretic antimony, or that made in the common manner. The great caution to inſure the ſucceſs, ſeems to be taking care of not carrying the fire too far before the addition of the laſt quantity of ſoap. Mem. Acad. Scien. Par. 1736.

Phosphorus *of the Bern-ſtone*, is a name given to ſtone (which, when heated, becomes a ſort of phoſphorus) from Bern, in Switzerland, the place where it is found.

This ſubſtance was ſent to the members of the Royal Academy at Paris, by M. Bourguet, and referred by them to the examination of M. du Fay, whoſe account of it is publiſhed in Mem. Acad. Paris, 1724.

The Bern-ſtone is of a moderate hardneſs, conſiderably pellucid, and uſually colourleſs, or whitiſh, though ſometimes with a tinge of green, yellow, or ſome other colours: it is compoſed of a number of plates or flakes, laid over one another in the manner of the iſland cryſtal; and, therefore, like that body is plainly a ſpar. It breaks into ſeveral faces, and has different angles; but of a ſomewhat determinate meaſure, the acute ones being of ſixty degrees, and the obtuſe ones of one hundred and twenty.

This ſtone, when heated at one of its angles with the flame of a lamp or candle, ſplits by means of the flame's inſinuating itſelf into the interſtices of the plates that are leſs firmly united; and theſe ſeparate, and ſome fragments uſually fly off with conſiderable violence. One of theſe pieces, carried into an obſcure place, appears ſurrounded with a blue flame, which laſts about a minute. And it is to be obſerved, that theſe pieces which fly off have all the ſhape of an irregular pyramid, with an uneven baſe. If this ſtone be put into a crucible and ſurrounded with coals, it becomes a very beautiful phoſphorus. The whole bottom of the crucible is ſeen, even though it be in broad daylight, ſhining with a bright and beautiful blueiſh white; and if it be carried into a dark place, the light is ſeen much more beautifully. If, after it is cold, it be again heated in a crucible, in the ſame manner, it ſhews the ſame bright appearance. After this, if it be tried a third time, it does not ſhine at all. According to all theſe phenomena, the effects of fire upon this ſtone ſeem to depend on a ſulphur contained in it, probably of the ſame nature with that which enters the compoſition of the metals. This may, by means of a heat, ſuch as that given by the candle or in the crucible, diſengage itſelf ſo far from the body of the ſtone as to take fire; and when it has burnt ſo long as to conſume itſelf, the luminous property of the ſtone ſeems to ceaſe.

The coloured gems are cryſtals of a peculiar kind, tinged with what has been called the ſulphur or phlogiſton of metals: this ſulphur gives them their colour, and conſequently it ought to give them the properties of the Bern-ſtone, if it were not too fixed to be diſſipated in the ſame eaſy manner, and to take fire in the diſſipation. And it appears, on trial, that the baſtard emeralds of Auvergne and other places, the matrix of the amethyſt, the fragments of ſome of the accidental jaſpers, the hyacinths, and ſome ſort of rubies, are all phoſphoruſes of the nature of the Bern-ſtone, but with different degrees of brightneſs. The mother of the emerald, the yellow jaſper, the water ſapphire, the malachite, the opal, and the garnet, have none of them any of this property.

Since the ſame ſulphurs, which take fire in the Bern-ſtone, are what give colour to theſe other ſtones, it ſhould ſeem, that thoſe, which are not of this phoſphorus kind, nor give a light after being heated, ſhould not loſe their colours in the fire; and this is found to be true in the garnet, which does not loſe any part of its colour, nor is it at all luminous; whereas the hyacinth, and ſome of the jaſpers and other ſtones, which loſe a part of their colour, not the whole, in the fire, become alſo in part luminous, or more ſo, in degree, according to the quantity of colour which they loſe. This, however, is no certain rule, ſince the mother of the emerald, the topaz, and ſome other ſtones, loſe all their colour, and yet are not at all luminous. The reaſon of this ſeems to be, that the ſulphurs are driven out of theſe ſtones ſo ſlowly, and in ſuch minute quantities, that they are not at any time collected into body enough to be capable of flame. There is nothing to be objected as to the Bern-ſtone ſhining; though they are uſually white, they may poſſeſs no ſmaller portion of ſulphurs than the coloured ſtones; only in thoſe the ſulphurs may be colourleſs, or white in themſelves. It may be poſſible alſo, that the ſulphurs in a ſtone of this kind may be diſperſed in ſuch ſmall molecules, as not to form a body ſufficient to give any colour; but when collected, in order to be driven off in the fire, they may then be ſufficient in quantity to give a blue tinge to the flame.

The iſland cryſtal, which is alſo a ſpecies of ſpar, and which greatly reſembles this Bern-ſtone in many particulars, flies to pieces alſo in the ſame manner, on being heated; and when carried into the dark, this alſo gives ſome ſparks of light, but they are few in number, and looſely ſcattered over the ſurface: when this ſtone is burnt a little in the crucible, there is ſome ſmall appearance of flame, with a ſmell fmell of fulphur, and the matter in the bottom of the crucible is found fhattered to pieces; but all the pieces are regular parallelopipeds, as was the original mafs.

It is to be obferved, that the Bern-ftone, and others of the fame kind, which only fhine in the dark, and that only for a few minutes, when firft taken out of the fire, are, properly fpeaking, endued with no other luminous quality than that of a burning coal; but their light, having been generally unobferved, and requiring darknefs to fhew it, has obtained for them the fpecious title of *phofphori*.

PHOSPHORUS, *Canton's*, is an artificial phofphorus, the method of preparing which was difcovered by the late ingenious Mr. Canton, and publifhed in the Phil. Tranf. for 1768, vol. lviii. p. 337, &c.

This is much fuperior to any fingle natural fubftance, and has the advantage of being very eafily and cheaply prepared. The procefs is as follows: calcine fome common oyfter-fhells, by keeping them in a good coal fire for half an hour; let the pureft part of the calx be pulverized, and fifted; mix with three parts of this powder one part of the flowers of fulphur; let this mixture be rammed into a crucible of about an inch and a half in depth, till it be almoft full; and let it be placed in the middle of the fire, where it muft be kept red-hot for one hour at leaft, and then fet by to cool: when cold, turn it out of the crucible, and cutting, or breaking it to pieces, fcrape off, upon trial, the brighteft parts; which, if good phofphorus, will be a white powder, and may be preferved by keeping it in a dry phial with a ground ftopple. The quantity of light which a little of this phofphorus gives, when firft brought into a dark room, after it has been expofed for a few feconds, on the outfide of a window to the common light of the day, is fufficient to difcover the time by a watch, if the eyes have been fhut, or in the dark, for two or three minutes before. By this phofphorus celeftial objects may be very well reprefented; as Saturn and his ring, the phafes of the moon, &c. if the figures of them, made of wood, be wetted with the white of an egg, and then covered with the phofphorus. And thefe figures appear to be as ftrongly illuminated in the night, by the flafh from a near difcharge of an electrified bottle, as by the light of the day. This phofphorus receives no injury from being expofed to the direct rays of the fun, which is the cafe of fome of the more delicate kinds, as Beccarius has remarked, and Lemery fuppofed with all. However, it cannot be expofed to moifture without lofing its property of imbibing and emitting light, and alfo its whitenefs. Mr. Canton found, that it was more affected by mixture with fpirit of wine than with ether. It had been long known, that heat promotes the expulfion of the light, which has been formerly imbibed by thefe phofphori. Mentzel, who wrote foon after the difcovery of Baldwin's phofphorus, afferted, that it had the property of becoming luminous by heat only; the fame fact was obferved by M. du Fay; but the principle on which it depended was difcovered by Beccarius, M. Margraaf, and Mr. Canton, independently of one another. Beccarius was firft of opinion with Mentzel, that the light was produced by heat; but finding by repeated trials, that, without previous expofing to the light, heat had no effect, he relinquifhed that opinion. M. Margraaf fell at firft into the fame miftake with Beccarius; but he afterwards obferved, that the phofphorus would not fhine by being placed upon a hot furnace, unlefs it had been expofed to the light two or three days before. Upon the whole, he concludes, that the light is held in this fubftance by attraction, and afterwards expelled by heat. Mr. Canton alfo, without any knowledge of the obfervations of Beccarius and Margraaf, found by a variety of experiments, that, when his phofphorus had imbibed light, and had emitted all that it could in the common ftate of the atmofphere, it would emit more upon the application of heat, but that a continuance of the fame degree of heat would only make it luminous for a certain time. Whence he infers, that there is a ftrong attraction between light and the particles of natural bodies: and that the ftrong vibrations into which heat throws them, compels them, as it were, to quit their hold of each other; and the light, which this phofphorus gives, by being heated to a certain degree, appears to be caufed by its throwing off adventitious particles, and not by any of its own; fince its light will decreafe, and be entirely gone, before the phofphorus be hot enough to fhine of itfelf, or to emit particles of light from its own body. Lemery and Mufchenbroeck have obferved, that the Bolognian phofphorus imbibes lefs light when hot than cold; becaufe it appears lefs bright when carried into a dark room; but this circumftance is accounted for by Mr. Canton, by its parting with its light fafter when hot than when cold, and, therefore, parting with more in the time of the conveyance from one place to another: and this, he alfo fays, feems to be the caufe why the Bolognian phofphorus never appears fo bright after it has been illuminated, and, confequently, in fome meafure heated, by the direct rays of the fun, as after it has been only expofed in the fhaded open air to the common light of the day. However, there is reafon to imagine, that the fame degree of heat, which difpofes the phofphorus to throw off the light after it has been imbibed, muft likewife render it indifpofed to receive it. For an account of the refult of Mr. Canton's experiments on this fubftance in favour of the materiality of light, fee LIGHT.

PHOSPHORUS, *Wilfon's*, a fubftance belonging to the clafs of folar phofphori, which Mr. B. Wilfon difcovered, and which is one of the fimpleft and moft powerful of all the phofphori belonging to this clafs. The method of preparing it is as follows: Select twenty oyfter-fhells, the thicker the better; then take from a fire that is brifkly burning, moft of the flaming coals, but not all of them; ftrew the fhells over the furface, and replace the coals that have been taken off. In about an hour's time take out the calcined fhells, breaking them as little as poffible; and after expofing them for a few minutes to the light, they will be found to have acquired a high degree of phofphorefcence, glowing in the dark, in a very beautiful manner, with moft of the prifmatic colours. If the fhells are fufficiently heated in a clofe crucible, they will exhibit prifmatic colours, chiefly blue and green, though not fo bright as by the former method. If the calcination is effected in an iron crucible, all thofe parts of the fhells that are in contact with the fides of the crucible will glow with a red light. The contact of inflammable matter, and particularly charcoal, with the fhells during calcination, appears very much to contribute to the brilliancy of the phofphorus: hence it is, that if the fhells are calcined in a crucible in contact with thin plates of fteel, the phofphorus thus produced will be much more bright, and of more various colours, than where plates of iron are employed; and, on the other hand, if flat pieces of charcoal are made ufe of, the intenfity of the colours, efpecially the blue, green, and red, is far greater than in thofe produced by fteel.

The colour of the light, in moft phofphori that have been prefented to the light, and that are then carried into the dark, is white or reddifh-white; but in Wilfon's phofphorus, not only white colours, but all thofe of the prifm make their appearance, fometimes being all united in a fingle fpecimen, at other times each piece exhibiting only one or two colours. In every fpecies of folar phofphorus, the light, after having been extinguifhed, may be increafed for any number of times, without the fmalleft apparent diminution of brilliancy, by fimple expofure for a few feconds to the light. If the phofphorus be moderately heated, when it is prefented to the light, its luminoufnefs will be very fenfibly augmented. If a common box fmoothing-iron, heated as ufual, be placed for half a minute on a fheet of dry white paper, and the paper be then expofed to the light, and afterwards examined in a very dark clofet, the whole paper will be luminous, and the part on which the iron box had ftood will be much more fhining than the reft. It is obferved that the variation of the temperature produces remarkable effects on phofphori, *after* having been expofed to the light. If a thin glafs tube be filled with Canton's or Wilfon's phofphorus, and as foon as it is brought into a clofet made very dark, be plunged half way into a freezing mixture for a few minutes, it will be found, on again withdrawing the tube, that the cold portion is much lefs luminous than the other; and if the freezing mixture has been fufficiently powerful, it will be entirely extinguifhed. The luminous property in this cafe is fufpended, and not exhaufted: for as the dark part of the tube begins to acquire the temperature of the furrounding air, its light will revive, and it will remain longer than that of the other part of the tube, in proportion to the time of its being kept in the freezing mixture. From hence it would feem to follow, that at a very low temperature the prefent clafs of folar phofphori would ceafe to exift. As cold retards, heat quickens the emiffion of light from phofphoric fubftances. If the tube juft mentioned be dipped half way into boiling water, the immerfed part will exhibit a great increafe of luftre, which in a minute or lefs time will be fucceeded by total darknefs; while the unheated part will fhine for a much longer time, though with lefs fplendour. If any one of thefe phofphori, kept in the dark till it is totally extinguifhed, be placed, without being again expofed to the light, in the warm hand, its luminoufnefs will for a fhort time be renewed; and if, when the hand fails to produce the effect, it be placed in boiling water, a further emiffion of light will take place; and, finally, it may be entirely exhaufted of its light, by being placed on a metallic plate, heated nearly to rednefs. Hence it appears, that there are two caufes of the extraordinary brightnefs exhibited by folar phofphorus, when ftrongly heated immediately on being introduced into the dark room: in the firft place, there is a greater quantity of light actually given out; and, fecondly, the whole is difcharged in perhaps a twentieth of the time in which even a part would be exhaufted at the common temperature.

Two theories have been propofed, in order to account for the origin of light in thefe fubftances. One theory afcribes it fimply to the folar light, which they had previoufly imbibed; and the other attributes it to the inherent light of the phofphorefcent fubftance itfelf. The advocates of the firft theory allege, that previous expofure to the light is neceffary to the phofphorefcence of thefe fubftances, and that the period of its greateft brilliance is the moment of its being placed in the dark, where it regularly and rapidly diminifhes till it becomes extinct. Beccaria's experiment is alfo urged in favour of this theory: he found that thofe phofphori, which in the ufual circumftances emit a white light, give out coloured rays in the dark, correfponding to thofe which they receive from the fun, with the interpofition of a plate of coloured glafs. The accuracy of this fact has been doubted. Du Fay's experiments, made before thofe of Beccaria, tend to a directly oppofite refult; the light emitted by the phofphorus being of the fame tint, whatever was the colour of the glafs through which the rays paffed to the phofphorus. Others have failed in repeating Beccaria's experiments. Mr. Wilfon, in particular, had made many experiments in reference to this point, which, with their refults, he has detailed in his Treatife on Phofphorus. His facts would lead us to conclude, that the phofphorefcent light is not merely that which was previoufly imbibed from the fun; and yet they do not prove that it is properly inherent in the phofphoric fubftance itfelf.

The folar phofphori may be excited not only by the rays of the fun, but by any other light that is fufficiently powerful; and thofe phofphorefcent fubftances which are moft brilliant, in confequence of expofure to the light of day, are moft eafily excited, as we might naturally expect, by other luminous bodies. However, the rays of the moon, even when concentrated in a lens, appear to be incapable of illuminating even the moft fenfible kinds of phofphori. The light of a fingle candle, or the momentary flafh from the explofion of a little gunpowder, or from an electrical difcharge, are fufficient to render Wilfon's phofphorus, when well prepared, very vifibly luminous. It is not very certainly known what is the effect of the different gafes on the luminous property of thefe bodies. Aikin's Dict. of Chem. and Min., art. PHOSPHORUS. See LIGHT.

PHOSPHORUS, *Fæcalis*, a very fine kind of phofphorus, exhibiting many wonderful phenomena, and prepared from human dung mixed with alum.

Mr. Homberg, who was the inventor of it, gives the method of preparing it in the following manner: take four ounces of human dung newly made, mix it with the fame quantity of roach alum grofsly powdered; put the mixture into a fmall iron ladle, capable of holding about a pint; fet it over the fire in a chimney, and it will melt together, and become as fluid as water; let it boil gently over a fmall fire, continually ftirring it with an iron fpatula till it is dry; it will then be difficult to ftir, but it muft be kept ftirring about, and all the lumps it runs into muft be broken, and what adheres to the fides of the ladle ftirred in and blended with the reft; this muft be continued till it is perfectly dry, and the ladle muft be now and then taken from the fire, and the matter ftirred about in it, that it may now grow red-hot. When the whole is thus perfectly dried, it will ftill be in little lumps, and when cold it muft be rubbed to powder in a metal mortar; it muft then be put into the ladle, and fet over the fire again; it will then become a little moift again, and run into clods and grumes, but it muft be again ftirred till dry; when cold it is to be powdered again, and a third time put into the ladle; and when perfectly dried this time, it is to be laid by in a paper in a dry place: thus is the firft or preparatory operation finifhed.

Take two or three drams of this powder, put it into a fmall matrafs, capable of holding an ounce and a half of water, and which has a neck fix or feven inches long; put a paper ftopper lightly into the neck of the matrafs; then take a fmall crucible of three or four fingers breadth high, put two or three fpoonfuls of fand into it, then fet the bottom of the matrafs on the fand, and take care that no part of it touches the fides of the crucible; fill up the reft of the crucible with fand, and let the whole body of the matrafs be covered with it; then fet the crucible in one of the common little earthen furnaces, and make a charcoal fire about it; for the firft half hour let the coals only reach up to the middle of the crucible, but afterwards lay them up to the rim in it; continue this fire about half an hour, or till the powder within the matrafs is red-hot; then pile up more charcoal

charcoal above the rim of the crucible, and continue this fire an hour, after which let the whole cool. There will ariſe a large quantity of fumes during the operation, and they will often throw out the ſtopper of the matraſs; but this muſt be replaced, and the fire a little abated in that caſe; when theſe fumes ceaſe, the fire may be raiſed without hurting the proceſs, when the crucible is ſo cool that it may be taken out of the furnace without burning the hands. This is to be done, and the matraſs is to be half raiſed out of the ſand, to make it bear the cold by degrees, and its mouth muſt then be ſtopped cloſely with a cork, inſtead of its paper ſtopper. If, on ſhaking the matraſs about, the matter falls into powder, it is a proof that the operation has been well performed; but if it hang together in form of a cake, it is a ſign that the matter was not well roaſted in the ladle before the putting it into the matraſs.

When the operation has been well performed, and the matter is in powder in the matraſs, pour out a ſmall quantity of it on a piece of paper, and immediately ſtop the matraſs again; the powder upon the paper will immediately fume and take fire, burning the paper, and any other combuſtible matter that is in the way. If there has been too much of the powder poured out of the matraſs, it muſt not be returned in again; for though that ſhould be done before it begin to ſmoke, yet it will certainly ſet fire to all that is in the matraſs: from this it may be eaſily ſeen alſo, that the matter cannot be emptied out of the matraſs into a phial, but muſt always be in the veſſel in which the calcination was made.

If too much alum be uſed, the powder will not take fire at all: it will be of different colours, according to the veſſel the firſt calcination was made in, and according to the degree of fire that was uſed; hence it is ſometimes black, ſometimes brown, ſometimes red, green, yellow, or white.

It takes fire equally well in the day-time and in the night, and that without the mixture of any other ſubſtance, or without the leaſt rubbing, or any other circumſtance beſide the mere expoſure to the air. In this it differs from all the other known artificial phoſphori; for that of urine requires a ſmall degree of heat, in order to its burning; the ſmaragdine phoſphorus requires a conſiderable degree; the Bononian ſtone does not ſhine, except after having been expoſed to the day-light; and all the others require violent rubbing, or a ſmart blow, to produce their light.

If it be deſired to keep this powder good for any time, it muſt be put in a dry place where there is not too much heat; the mouth of the matraſs muſt be kept cloſe ſtopped, and its body covered with paper; and the place where it ſtands muſt not be in too ſtrong a light; for the open day-light has been often known to weaken its power, and, in fine, wholly to ſpoil it through the glaſs. Mem. Acad. Par. 1711. See PYROPHORUS.

PHOSPHORUS, *Fulgurating*. See FULGURATING.

PHOSPHORUS *Metallorum*, a name given by ſome chemiſts to a preparation of a certain mineral ſpar, which is found in the mines of Saxony, and other places, where there is copper. The ſpar to be uſed on this occaſion is that kind which is tinged green, and from its, in ſome degree, reſembling the colour of the emerald, is called by ſome *pſeudoſmaragdus*, and by others *lapis ſmaragdi mineralis*. This is to be powdered very fine, and this powder is to be laid on a flat plate of copper, iron, or any other metal: this plate is then to be ſet over ſome lighted charcoal, and the whole placed in a dark place. The ſpar will receive its neceſſary degree of heat for ſhining long before the metal will, and, conſequently, as ſoon as it begins to ſhine, the fire is not to be made any briſker. While the plate of metal is held in this degree of heat, and does not appear at all red, the powder upon it will ſhine like a lighted coal, and will continue ſo for ſome time. If it be removed away, and ſuffered to cool, it will be fit to repeat the experiment a ſecond time with, but its light will not be ſo ſtrong as before. Phil. Tranſ. N° 244. p. 365.

PHOSPHORUS *of Sulphur*, the name given by the French academicians to a new-diſcovered ſpecies of phoſphorus, which readily takes fire on being expoſed to the open air. See PYROPHORUS.

The invention was M. Le Fevre's, and the proceſs is this: the ingredients are two drams of common ſulphur, half an ounce of ſteel filings, ten grains of colophony, and ſix drams of common water. Theſe things being all weighed and ſet apart, powder about half a dram of the ſulphur in a ſmall mortar, then add the colophony, and afterwards the remainder of the ſulphur. When this is all reduced to a fine powder, put in the filings of ſteel, and rub the whole together till it is ſo thoroughly mixed, that the ſteel does not appear, but the colour of the whole looks every where uniform and regular; then add about twenty drops of the water; and after beating the whole together add as much more, and continue to do ſo till the maſs is of the ſubſtance of a paſte, but not too moiſt. Put this paſte into a ſmall matraſs that will contain about three ounces, and pour on it more of the water till it ſwim above the ſurface of the paſte near a quarter of an inch. The matter of the paſte will then break, and appear in form of a granulated powder under the water; put the matraſs on a ſand-furnace, but give it no greater heat than that the hand can bear to lie upon the matraſs. When it begins to heat, the mixture will ferment and ſwell, and become black; it is then to be ſtirred with an iron rod, and a little more water muſt be added every quarter of an hour, till the whole is uſed. The matter will then be very black and liquid; and it is to be then taken from the fire, and ſet by for the whole night. This is the firſt and moſt eſſential part of the operation, and in this great care is to be taken that the fire be not too violent; for if the ſulphur be burnt the operation will be ſpoiled; and the matter would ferment ſo high as to run over at the mouth of the veſſel.

To finiſh the operation, a little water muſt be added to the matter, ſo as to ſwim over it, and the veſſel muſt be again ſet in the ſand, and a ſtronger fire given than before; this is known to be ſtrong enough when there is any humid vapour obſerved to ariſe out of the mouth of the veſſel. This fire is to be continued about two hours, that the greater part of the humidity may be evaporated; which is known by the iron rod finding ſome reſiſtance when put into the veſſel, and the matter it brings up being granulated and ſolid, or no longer moiſt, it muſt then be immediately taken from the fire, and the whole is then finiſhed. It is neceſſary to be very exact in this laſt and critical minute; for a very little longer ſtanding on the fire will burn the ſulphur, and render all the former care of no effect. The black matter remaining in the matraſs is to be taken out, and the ſides ſcraped clean with an iron rod; any piece of this that happens to fall upon a paper takes fire in a very little time, and burns away like the other phoſphorus. The proceſs is a very nice one, but, by obſerving all the rules here laid down, ſeveral perſons have ſucceeded in making the phoſphorus to perfection: the whole intent of the operation ſeems to be to join together the minute particles of ſteel and ſulphur, which when thus joined cannot fail to be very inflammable, and to take

fire

fire on receiving the ſmalleſt humidity from the air to make them ferment.

It cannot but be obſerved, that this phoſphorus is founded on Lemery's experiments of ſteel and ſulphur taking fire together; but this is a much more nice and accurate operation, and a fine improvement on the original plan, which was only by mixing large quantities of ſteel filings and ſulphur together into a paſte with water, and burying this in the earth to make it take fire of itſelf, and thus repreſent the natural phenomena of volcanos, thunder, lightning, &c. Mem. Acad. Par. 1728.

John Baptiſt Beccaria has ſhewn, Phil. Tranſ. vol. lxi. part i. art. 25. that the phoſphorus compoſed of ſulphur and calcareous earth, imbibed the peculiar coloured rays to which it had been expoſed. Thus, having expoſed different phoſphoric pieces to rays of the ſun tranſmitted through green, yellow, and red cryſtals, he obſerved, that each of them, when afterwards viewed in the dark, exhibited that colour to which it had been expoſed. This obſervation is deciſive in favour of the opinion, that phoſphorus of this kind emits the ſame light that it receives, and no other; and that the light is not produced, but expelled by heat.

This experiment, which has often failed, for want of employing good glaſſes, or on account of the weakneſs of the ſolar rays, has been repeated by profeſſor Allamand of Leyden; who ſays, that having expoſed a prepared (probably by calcining it with ſome ſulphureous ſubſtance) piece of the Bononian calcareous phoſphorus to the coloured rays of the ſun, after their being ſeparated by one of his priſms, and looking to it in the dark, he found the phoſphorus gave the colour of the ſeparated rays to which it had been expoſed.

Phosphorus, *Aquatic*, a name given by Dr. Leigh, in his Hiſtory of Lancaſhire, to a water found near Wigan in that county, which takes fire on holding a lighted candle to it. It is not properly the water, however, that takes fire in this caſe, but a ſteam which burſts out of the ground with it. The author alſo calls it a ſulphurated water; but that very improperly, for it contains no ſulphur, but only iſſues out with this bituminous vapour.

Phosphorus, in *Aſtronomy*, is the morning ſtar, or the planet Venus, when ſhe goes before the ſun.

The Latins call it *Lucifer;* the French *etoile de berger;* the Greeks *phoſphorus*, from φως, *light*, and φερω, *I bear*, or *bring*.

PHOSSA, in *Ornithology*, a name underſtood by ſome to expreſs the whole genus of pigeons, but more properly it is the name of one ſpecies only, the *palumbus torquatus*, or ring-dove. See Columba *Palumbus*.

PHOTIÆ, in *Ancient Geography*, an epiſcopal town of Aſia, in Phrygia Salutaris.

PHOTINIANS, in *Eccleſiaſtical Hiſtory*, a ſect of ancient heretics, in the fourth century, who denied the divinity of Jeſus Chriſt.

They took their name from Photinus their chief, who was biſhop of Sirmium, and a diſciple of Marcellus. This prelate publiſhed, in 343, his opinions concerning the Deity, which were equally repugnant to the orthodox and Arian ſyſtems. He maintained, that Jeſus Chriſt was born of the Holy Ghoſt and the Virgin Mary; that a certain divine emanation (which he called the Word) deſcended upon this extraordinary man; that on account of the union of the divine word with his human nature, Jeſus was called the ſon of God, and even God himſelf; and that the Holy Ghoſt was not a diſtinct perſon, but a celeſtial virtue proceeding from the Deity. He was condemned by both parties in the councils of Antioch and Milan, held in the years 345 and 347, and by the council of Sirmium in 351. He was afterwards degraded from the epiſcopal dignity, and died in exile, in the year 372 or 375. His opinion was afterwards revived by Socinus.

PHOTINUS, in *Biography*. See the preceding article.

PHOTINX, or crooked flute: an Egyptian inſtrument. Its ſhape was that of a bull's horn, as may be ſeen in many gems, medals, and remains of ancient ſculpture. Not only the form of this inſtrument, but the manner of holding it, is deſcribed by Apuleius, in ſpeaking of the myſteries of Iſis: "Afterwards," ſays this author, "came the flute players, conſecrated to the great Serapis, often repeating upon the crooked flute turned towards the right ear, the airs commonly uſed in the temple." All the repreſentations in ſculpture which we have ſeen of this inſtrument, have ſo much the appearance of real horns, that they encourage a belief of its great antiquity; and that the firſt inſtruments in uſe of this kind, were not only ſuggeſted by the horns of dead animals, but that the horns themſelves were long uſed as muſical inſtruments, at leaſt thoſe ſounded by the Hebrew prieſts at the ſiege of Jericho, we are repeatedly told, were trumpets made of ram's horns.

PHOTIUS, in *Biography*, a patriarch of Conſtantinople in the ninth century, was of a noble Conſtantinopolitan family. His wealth and intereſt raiſed him to the higheſt offices of the ſtate, while he enjoyed the reputation of being the moſt learned and accompliſhed man of his age. When he was a captain of the guards he was ſent on an embaſſy to the caliph of Bagdad, and he employed his leiſure in reading and literary compoſition. He afterwards became ſecretary of ſtate under the emperor Michael III. In this ſituation he contracted an intimacy with the emperor's uncle, who, after he had procured the exile of the patriarch Ignatius, perſuaded the emperor to raiſe Photius to that dignity. At this time he was a layman, but in the ſpace of ſix days he went through the gradations requiſite for prieſt's orders, and on Chriſtmas day, 858, he was conſecrated patriarch of Syracuſe. Photius was recognized by the metropolitans of his patriarchate, and proceeded to the ſolemn depoſition of Ignatius. The elevation of Photius cauſed a great ſchiſm, and he exerciſed ſeverities on thoſe who adhered to his rival. The emperor Baſil expelled him in 869, an act that was confirmed by a council ſummoned for the purpoſe, who pronounced an anathema, as well as depoſition, againſt the fallen patriarch. Afterwards he obtained the emperor's favour, and on the death of Ignatius he reſumed his dignity with a ſtrong hand. Baſil obtained from pope John VIII. his conſent to the meaſure, which was ratified at a council holden in preſence of the pope's legates in 879. In 886 Leo cauſed him again to be deprived, and confined in a monaſtery, where he died in 891. His principal works are; 1. "Myriobiblon or Bibliotheca," compoſed on his embaſſy to Bagdad, conſiſting of an abſtract and critical judgment of 280 different writers in the departments of hiſtory, oratory, grammar, philoſophy, theology, &c. of many of whom no other relic remains: this was printed by Heſchelius in 1601, but the beſt edition is that of Rouen, Gr. and Lat. 1653. The book which at preſent bears that name, is not the real production of Photius; and it has been ſuppoſed that not more than half of it can be ſafely attributed to this learned and turbulent biſhop. 2. "Nomocanon," or a collection of the canons of the church, printed with the commentaries of Balſamon at Paris in 1615. 3. "Epiſtolæ," or a collection or Letters, printed by R. Mountagu in 1651. 4. His celebrated

celebrated Lexicon, which, imperfect and mutilated as it is, is more valuable to the critical scholar than ten myrobibla. The various MSS. of this Lexicon, in different libraries on the continent, are mere transcripts from each other, and originally from one, venerable for its antiquity, which was formerly in the possession of the celebrated Thomas Gale, and which is now deposited in the library of Trinity college, Cambridge. This MS., which is on parchment, bears such evident marks of antiquity, that it may not unreasonably be supposed to have been a transcript from the author's copy. It is written in various hands. The compendia, which are used in some parts of it, are extremely difficult to decipher, though, on the whole, they are less so than the contractions which occur in many MSS., and particularly those in the library of St. Germain. A copy of this Lexicon, at Florence, was transcribed about the end of the 16th century, by Richard Thomson, of Oxford, who probably intended to publish it. (See Scaliger Epist. p. 503. printed 1715.) Professor Porson had transcribed and corrected this valuable Lexicon for the press, and after it had been consumed by fire, he began the task afresh, and such were his incredible industry and patience, that he completed another transcript in his own exquisite hand-writing. Mr. Porson's copy of the Codex Galeanus is said to be among the papers of that incomparable scholar, which are preserved by the learned society of which he was long a distinguished ornament. But whilst the publication of it was anxiously expected and delayed, an edition appeared at Leipsic in 1808, by Godfrey Hermann, from two MSS., both of them extremely inaccurate.

PHOTOMETER, or *Measurer of Light*, as the name, derived from φως, *light*, and μετρω, *I measure*, imports, in *Optics*, an instrument contrived for measuring the different intensities of light. That some luminous bodies give a stronger and others a weaker light, and that some reflect more light than others, are facts that have been always known, and that are sufficiently obvious. But it is not easy to estimate with accuracy the comparative intensity of light afforded by any two, or more, luminous objects. For this purpose, it is necessary to assume as a principle, that the same quantity of light, diverging in all directions from a luminous body, remains undiminished at all distances from the centre of divergence. Thus, we must suppose, that the quantity of light falling on every body is the same as would have fallen on the place occupied by its shadow; and if there were any doubt of the truth of the supposition, it might be confirmed by some simple experiment. It follows that, since the shadow of a square inch of any surface occupies, at twice the distance of the surface from the luminous point, the space of four square inches, the intensity of the light diminishes as the square of the distance increases. We can judge with tolerable accuracy of the equality of two lights by the estimation of the eye; but we cannot form any idea of the proportions of light of different intensities. If, however, we remove two sources of light to such distances from an object, that they may illuminate it in equal degrees, we may conclude that their original intensities are inversely as the squares of their distances. To this subject Mr. Bouguer seems to have first directed his attention. The methods which he used for measuring the proportion of different lights, are described by Dr. Priestley in his "History of Light, &c." as follow. He took two pieces of wood or pasteboard, in which he made two equal holes, over which he drew pieces of oiled or white paper. Upon these holes he contrived that the light of the different bodies he was comparing should fall, while he placed a third piece of pasteboard, to prevent the two lights from mixing with one another. Then placing himself sometimes on one side and sometimes on the other, but generally on the opposite side of this instrument, with respect to the light, he altered their position, till the papers in the two holes appeared to be equally enlightened. This being done, he computed the proportion of their light by the squares of the distances at which the luminous bodies were placed from the objects. If, for instance, the distances were as 3 and 9, he concluded the light they gave were as 9 and 81.

When any light was very faint, he sometimes made use of lenses, in order to condense it, and he enclosed them in tubes or not, as his particular application of them required. To measure the intensity of light proceeding from the heavenly bodies, or reflected from any part of the sky, he contrived an instrument resembling a kind of portable camera obscura. He had two tubes, of which the inner was black, fastened at their lower extremities by a hinge. At the bottom of these tubes were two holes, three or four lines in diameter, covered with two pieces of fine white paper. The two other extremities had each of them a circular aperture, an inch in diameter; and one of the tubes consisted of two, one of them sliding into the other, which produced the same effect as varying the aperture at the end. When this instrument is used, the observer has his head, and one end of the instrument so covered, that no light can fall upon his eye, besides that which comes through the two holes above mentioned, while an assistant manages the instrument, and draws out or straightens one tube, as the observer directs. When the two holes appear equally illuminated, the intensity of the lights is judged to be inversely as the squares of the lengths of the tubes. In using this instrument, it is necessary that the object should subtend an angle larger than the aperture of the tube from its other end; for, otherwise, the lengthening of the tube has no effect. To avoid, in this case, making the instrument of an inconvenient length, or making the aperture too narrow, he has recourse to another expedient. He constructs an instrument, consisting of two object-glasses, fixed in the ends of two tubes, six or seven feet, or, in some cases, ten or twelve feet long, and having their foci at the other ends. At the bottom of these tubes are two holes, three or four lines in diameter, covered with a piece of white paper; and this instrument is used exactly like the former. If the two objects to be observed by this instrument be not equally luminous, the light that issues from them must be reduced to an equality, by diminishing the aperture of one of the object-glasses; and then the remaining surface of the two glasses will give the proportion of their lights. But, for this purpose, the central parts of the glass must be covered, in the same proportion with the parts near the circumference; because the middle part of the glass is thicker, and less transparent than the rest. If all the objects to be observed lie nearly in the same direction, our author observes, that the two long tubes may be reduced into one, the two object-glasses being placed close together, and one eye-glass sufficing for them both. The instrument will then be the same with that of which he published an account in 1748, and which he called a heliometer, or astrometer. (See HELIOMETER.) For some results of the application of these methods for determining the comparative intensities of the light proceeding from different luminous bodies in different circumstances, see LIGHT. Count Rumford has used the first of Bouguer's methods, and contrived an instrument for this purpose, called the "Photometer," of which he has given a description and drawing in the Philosophical Transactions for 1794, vol. lxxxiv. art. 9. The principle upon which it is grounded is, that if two lights shine upon the same surface, at equal obliquities, and an opaque body be interpofed, the two fhadows it will produce muft differ in blacknefs or intenfity in the fame degree. For the fhadow formed by intercepting the greater light will be illuminated by the fmaller light only, and reverfely, the other fhadow will be illuminated by the greater light: that is, the ftronger light will be attended with the deeper fhadow. But it is eafy, by removing the greater light to a greater diftance, to render the illumination it produces at the common furface equal to that afforded by the lefs. Experiments of this kind may be conveniently made by faftening a fheet of white paper againft the wall of a room; and placing the two candles or lights intended to be compared, fo that the ray of light from each fhall fall with nearly the fame angle of incidence upon the middle of the paper. In this fituation, if a book or other object be held to intercept part of the light which would have fallen on the paper, the two fhadows may be made to appear, on feparate furfaces, and alfo a third or perfect fhadow, from which both lights are excluded, may be exhibited. If one or both of the lights be removed directly towards or from the paper, as the appearances may require, until the two fhadows near the upper angular point of the perfect fhadow have the fame intenfity, the quantities of light emitted by each will be as the fquares of the diftances from the paper. By fome experiments made in this way, in the year 1785, Mr. Nicholfon (fee his Journal, vol. i.) was fatisfied that the degree of illumination could be thus afcertained, to an 80th or 90th part of the whole.

Count Rumford, in his " Account of a Method of meafuring the comparative Intenfities of Light," directs two burning candles, lamps, or other lights that are to be compared, to be placed at equal heights upon two light tables, or moveable ftands in a darkened room; let a fheet of clean white paper be equally fpread out, and faftened upon the wainfcot or fide of the room, at the fame height from the floor with the lights, and let the lights be placed over-againft this fheet of paper, at the diftance of fix or eight feet from it, and fix or eight feet from each other, in fuch a manner, that a line drawn from the centre of the paper, perpendicular to its furface, fhall bifect the angle formed by lines drawn from the lights to that centre; in which cafe, confidering the fheet of paper as a plane fpeculum, the one light will be precifely in the line of reflection of the other.

This may be eafily performed, by actually placing a piece of a looking-glafs, fix or eight inches fquare, flat upon the paper, in the middle of it, and obferving by means of it the real lines of reflection of the lights from that plane, removing it afterwards as foon as the lights are properly arranged.

When this is done, a fmall cylinder of wood, about a quarter of an inch in diameter, and fix inches long, muft be held in a vertical pofition, about two or three inches before the centre of the fheet of paper, and in fuch a manner, that the two fhadows of the cylinder correfponding to the two lights may be diftinctly feen upon the paper.

If thefe fhadows fhould be found to be of unequal denfities, which will almoft always be the cafe, then that light whofe correfponding fhadow is the denfeft, muft be removed farther off, or the other muft be brought nearer to the paper, till the denfities of the fhadows appear to be exactly equal; or in other words, till the denfities of the rays from the two lights are equal *at the furface of the paper*; when, the diftances of the lights from the centre of the paper being meafured, the fquares of thofe diftances will be to each other as the real intenfities of the lights in queftion at their fources.

If, for example, the weaker light being placed at the diftance of four feet from the centre of the paper, it fhould be found neceffary, in order that the fhadows may be of the fame denfity, to remove the ftronger light to the diftance of eight feet from that centre, in that cafe, the real intenfity of the ftronger light will be to that of the weaker as 8^2 to 4^2; or as 64 to 16; or 4 to 1; and fo for any other diftances.

It is well known, that the intenfity of any quality proceeding from a centre in ftraight lines in all directions, like the light emitted by a luminous body, at any given diftance from that centre will be as the fquare of that diftance inverfely; and hence it is clear, that the intenfities of the lights in queftion at their fources, muft be to each other as the fquares of their diftances from that given point *where their rays uniting, are found to be of equal denfity*. For putting $x =$ the intenfity of B; if P reprefents the point where the rays from A and from B meeting, are found to be of equal denfity or ftrength, and if the diftance of A from P be $= m$, and the diftance of B from the fame point $P = n$; then, as the intenfity of the light of A at P is $= \frac{x}{m^2}$, and the intenfity of the light of B at the fame place $= \frac{y}{n^2}$, and as it is $\frac{x}{m^2} = \frac{y}{n^2}$ by the fuppofition, it will be $x : y :: m^2 : n^2$.

That the fhadows being of equal denfity at any given point, the intenfities of the illuminating rays muft of neceffity be equal at that point alfo, is evident from hence, that the total abfence of light being perfect blacknefs, and the fhadow correfponding to one of the lights in queftion being deeper or fainter, according as it is more or lefs enlightened by the other, when the fhadows are equal, the intenfities of the illuminating rays muft be equal likewife.

In removing the lights, in order to bring the fhadows to be of the fame denfity, care muft be taken to recede from, or advance towards the centre of the paper in a ftraight line, fo that the one light may always be found exactly in the line of reflection of the other; otherwife the rays from the different lights falling upon the paper, and confequently upon the fhadows, at different angles, will render the experiment fallacious.

When the intenfity of one ftrong light is compared with the intenfities of feveral fmaller lights taken together, the fmaller lights fhould be placed in a line perpendicular to a line drawn to the centre of the paper, and as near to each other as poffible; and it is likewife neceffary to place them at a greater diftance from the paper than when only fingle lights are compared.

In all cafes, it is abfolutely neceffary to take the greateft care that the lights compared be properly trimmed, and that they burn clear and equally, otherwife the refults of the experiments will be extremely irregular and inconclufive.

To afcertain by this method the comparative denfities, or intenfities of the light of the moon, and of that of a candle, the moon's direct rays muft be received upon a plane white furface, at an angle of incidence of about 60°, and the candle placed in the line of the reflection of the moon's rays from this furface; when the fhadows of the cylinder correfponding to the moon's light, and to that of the candle, being brought to be of equal denfity, by removing the candle farther off, or bringing it nearer to the centre of the white plane, as the occafion may require, the intenfity of the moon's light will be equal to that of the candle *at the given diftance of the candle from the plane.*

To afcertain the intenfity of the light of the heavens by day or by night, this light muft be let into a darkened room through a long tube, blackened on the infide, when its intenfity tenſity may be compared with that of a candle or lamp, by the method above deſcribed.

To determine the intenſity of the direct rays of the ſun, compared to the light emitted by any of our artificial illuminators, it may perhaps be neceſſary, conſidering the almoſt inconceivable intenſity of the ſun's light, to make uſe of ſome further contrivances and precautions, but I am convinced, however, (ſays the author,) that it may be done, and that even with a very conſiderable degree of preciſion. And when the relative intenſity of the ſun's light at the ſurface of the earth, compared with the intenſity of the light of a given lamp, placed at a given diſtance, and burning with a flame of given dimenſions, ſhall be known; it will then be eaſy, from the known ſize and diſtance of the ſun, to compute the relative denſity of his light at *his* ſurface, compared to the denſity of the light of the flame of the lamp at the ſurface of that flame.

The intenſity of the light emitted in the combuſtion of iron or of phoſphorus in dephlogiſticated air, as alſo that of all other burning, or red-hot bodies, may be compared and determined by this method with the greateſt facility and exactneſs.

Count Rumford afterwards found it expedient to make ſome alterations in the inſtruments with which he conducted his experiments: and he thus deſcribes them in their finiſhed ſtate, when he denominated the whole apparatus combined a "photometer." For an account of the conſtruction of this inſtrument, of the purpoſes to which it is capable of being applied, and of the author's experiments with it, we refer to the Phil. Tranſ. *ubi ſupra.*

Profeſſor Leſley has invented an inſtrument for the ſame purpoſe, and under the ſame name, which he deſcribes as being conſtructed in the ſame manner with his *hygrometer*, only that the upper ball is blown of black glaſs, or is blackened, and the lower one is quite diaphanous, and free of ſpecks. The former detains the incident light, while the latter tranſmits it freely. But light, in proportion to its abſorption, cauſes heat, whether uniting with bodies it really conſtitutes the matter of heat, or only excites heat in the act of combination. But though the black ball acquires conſtant additions of heat, its temperature will not uniformly and perpetually increaſe; for the accumulated heat will at laſt be conducted off by the ſurrounding air exactly as it is received. The depreſſion of the liquor, therefore, will meaſure the momentary afflux of light. To prevent the irregular effects of winds, which might accelerate that diſperſion, the inſtrument is incloſed within a glaſs caſe. But this caſe ſerves alſo an important purpoſe, for, by confining the circulation of the ambient air, which alone transfers the continual augmentation of heat, it doubles the performance of the inſtrument. The cylindrical caſe ſhould be made of clear glaſs neatly rounded over, and hermetically ſealed at the end. Its width is not of much importance, only it ſhould leave a free ſpace not leſs than $\frac{1}{10}$th of an inch round the balls, and at leaſt half an inch at the top. Indeed both the ſize and form may be regulated by convenience, for I found (ſays the profeſſor) a receiver of 2200 inches to afford quantities ſcarcely one-tenth leſs than thoſe given by a caſe of the ordinary dimenſions.

Since this inſtrument was firſt conſtructed, in the autumn of 1797, Mr. Leſley has been delighted with the nicety of its performance. It not only meaſures the direct rays of the ſun, but the reflected light of the ſky, for which it is principally deſigned. It is ſenſible to every fluctuation of the atmoſphere, marks the progreſs and decline of the light of day, and the periodic increaſe and diminution of the brightneſs of the year. It enables us likewiſe to eſtimate other lights, ſuch as the flame of a candle. By comparing two photometers, it is eaſy to determine the relative properties of different coloured ſubſtances, in reflecting, abſorbing, and tranſmitting light. In the ſame manner, they will determine the queſtion, whether the particles of light are ſpread over the priſmatic ſpectrum with equal intenſity. By help of this inſtrument, too, we can meaſure the quantity of light tranſmitted through various diaphanous bodies, and that reflected or abſorbed at different angles of incidence from poliſhed or rough ſurfaces; in ſhort, perform with the utmoſt facility all thoſe ingenious experiments which have exerciſed the ſagacity of Bouguer and Lambert. Another ſet of inquiries, for which the photometer is nicely calculated, is to diſcover the conducting powers of different fluids for heat. If the glaſs caſe, for inſtance, be filled with a gas of higher conducting power than common air, the inſtrument will be proportionally leſs affected by the ſame afflux of light, ſince thoſe are the two balancing conditions. With air, too, of different denſities, the effects are materially different. In that way the author has examined various liquids and gaſes, nay jellies and ice. His experiments on theſe and other points are completed, and afford reſults which are ſatisfactory and important. For a farther account of this inſtrument, and of a curious and vabluable collection of facts eſtabliſhed by means of it, we refer to Leſlie's "Short Account of Experiments and Inſtruments on the Relation of Heat to Air and Moiſture," 8vo. See *Differential* THERMOMETER.

PHOTOSCIATERICA, a term which ſome authors uſe for the art of dialling.

The name is derived hence, that the art not only ſhews the hours by the ſhadow of a gnomon, whence it is called *ſciaterica*, from σκια, *ſhadow;* but ſometimes alſo by means of the ſun's light, as in ſpot dials, reflecting dials, &c. from φως, *lux*, *light.*

PHOVIBAGINA, in *Ancient Geography*, a town of Aſia, in Galatia, belonging to the Trocmi. It is called by Ptolemy Cariſſa and Duduſa.

PHOXINUS, in *Ichthyology*, a ſpecies of *Cyprinus;* which ſee.

PHOXOS, Φοξος, one with an acuminated or faſtigiated head, that is, ſharpened toward the top; the eminences of the forehead or occiput, or both, being depreſſed, or one or both of thoſe parts beyond meaſure prominent. But phoxoi are properly thoſe who have the top of their head very much faſtigiated and turbinated, and conſequently deformed. Therſites is deſcribed in Homer with ſuch a head.

PHRAATA, in *Ancient Geography*, a town of Aſia, which belonged to the Medes, according to Appian.

PHRAATIS GAZA, an iſland of Aſia, in the courſe of the Euphrates, which was of great extent, and fortified by a wall; ſituated W.N.W. of Anatho.

PHRADRA, a town of Drangiana, called alſo Prophthaſia. Steph. Byz.

PHRÆNIAN, in the *Botanical Writings of the Ancients*, a name given to a kind of anemone, uſed in making garlands and other ornaments.

PHRAGANDÆ, in *Ancient Geography*, a people of Thrace, on the confines of Macedonia.

PHRAGONIS, an epiſcopal town of Egypt, according to the acts of the council held at Alexandria in the year 562.

PHRANGI, a people of Italy, in the vicinity of the Alps. Steph. Byz.

PHRANZA, PHRANZES, GEORGE, in *Biography*, a modern Greek hiſtorian, was from his youth employed in the ſervice of the Byzantine court, and was the favourite chamberlain of the emperor Manuel Palæologus, who died A.D. 1427, when Phranza was 24 years of age. He was mafter of the wardrobe to his fucceffor John, and alfo to Conftantine, the laft emperor of the Eaft, by whom he was fent ambaffador to the courts of Georgia and Trebifond, for the purpofe of negociating a marriage for the young fovereign. When the Turks took Conftantinople, Phranza with his family were made flaves. In a few months, he and his wife were ranfomed; but his two children, a fon and a daughter, were feized for the feraglio, and loft to their unhappy parents. After this, Phranza became domeftic to prince Thomas, brother of the deceafed Conftantine, who employed him in various embaffies. He affumed the monaftic habit before his death, which took place at an advanced age. At the requeft of fome noble Corcyreans, he drew up a chronicle of the affairs relating to Conftantinople and the Morea, to moft of which he had been an eye-witnefs. This work is brought down to 1461; but though there are many MSS. of the Greek original extant in libraries, it has been publifhed only in the Latin verfion, or abftract of Pontanus, which, according to Gibbon, is very deficient in accuracy and elegance.

PHRASE, Phrasis, Φρασις, of φραζω, *I fpeak*, in *Grammar*, an elegant turn or manner of fpeech, peculiarly belonging to this or that occafion, this or that art, or this or that language.

Thus we fay, an Italian phrafe, an eaftern phrafe, a poetical phrafe, or a rhetorical phrafe.

A few elegant phrafes, pertinently applied, are an ornament of difcourfe; but, if they come too thick, they have an ill effect, and make the ftyle favour of affectation.

Phrase is fometimes alfo ufed for a fhort fentence, or fmall fet or circuit of words, conftructed together.

In this fenfe, father Buffier divides phrafes into *complete* and *incomplete*.

Phrafes are *complete*, where there are a noun and verb, each in its proper function; *i. e.* where the noun expreffes a fubject, and the verb the thing affirmed of it. They are *incomplete*, where the noun and the verb, together, only do the office of a noun, as confifting of feveral words, without affuming any thing, and which might be expreffed in a fingle word.

Thus, *that which is true* is an incomplete phrafe, which might be expreffed in one word, *truth*: as, that which is true fatisfies the mind, *i. e.* truth fatisfies the mind.

Phrase, *Phrafe*, Fr., in *Mufic*, denotes the continuance of an air or harmony, which forms, without interruption, a fenfe more or lefs complete, and which is terminated by a cadence more or lefs perfect. In melody the phrafe is conftituted by the air; but in harmony, it is a regular feries of concords, united together by diffonances expreffed or underftood.

Phrafe is frequently ufed as fynonimous with *paffage*, in mufic. It is in the invention of mufical phrafes, in their proportion and texture, that the true beauties of mufic confift. A compofer who accents and phrafes his paffages well, is, according to Rouffeau, a man of wit. Upon this principle, Haydn's mufic is full of *bons mots*. A finger who feels, who marks and accents his phrafes well, is a man of tafte; but he who only fees crotchets and quavers, keys, meafure, and intervals in mufic,—in fhort, who only fings in time and tune, however ready and certain he may be, if he feels not the accents and phrafeology of what he executes, is nothing more than a vulgar ballad-finger.

PHRASEOLOGY, Phraseologia, Φρασεολογια, a collection of the phrafes, or elegant expreffions, in any language.

PHRAT, the name anciently given to the river *Euphrates*; which fee. Phrat is mentioned in fcripture, and is faid to have two derivations from the Hebrew, *phar* or *pharatz*, to fpread, and *pharah*, to produce fruit or flowers. Vincent.

PHRATRIARCHUS, Φρατριαρχος, among the Athenians, a magiftrate that prefided over the *phratria*, or third part of a tribe. He had the fame power over the phratria, that the phylarchus had over the tribe.

PHREATA, in *Ancient Geography*, a town of Cappadocia, in Garfauria. Ptolemy.

PHREATIS, or Phreattium, in *Greek Antiquity*, a court pertaining to the civil government of Athens, which was fituated upon the fea-fhore in the Piræus, and derived its name απο τȣ φρεατος, becaufe it ftood in a *pit*, or, as others fuppofe, from the hero Phreatus. The caufes heard in this court were fuch as concerned perfons that had fled out of their own country for murder, or thofe that fled for involuntary murder, and had afterwards committed a deliberate and wilful murder. The firft perfon that was tried in this place was Teucer, upon a groundlefs fufpicion, that he had been acceffory to the death of Ajax. The criminal was not permitted to come to land, or fo much as to caft anchor, but pleaded his caufe in his bark; and, if found guilty, was committed to the mercy of the winds and waves, or, as fome fay, fuffered there condign punifhment; if innocent, he was only cleared of the fecond fact, and, according to cuftom, underwent a twelvemonth's banifhment for the former. Potter's Gr. Antiq. vol. i. p. 111.

PHRENES, Φρενες, in *Anatomy*, the diaphragm.

It was thus called by the ancients, from φρην, *mind*; becaufe they imagined this to be the feat of the rational foul. Hence,

PHRENESIS, Phrensy, or *Diftraction*. See Phrenitis and Paraphrenitis.

PHRENETIC Nerves, called alfo *diaphragmmatic* and *ftomachic nerves*, in *Anatomy*, are nervous branches derived from the cervical nerves, which, joining in a trunk, run through the mediaftinum undivided, till, arriving near the diaphragm, they again divide, and fend off divers branches, fome into the mufcular, others into the tendinous part thereof.

PHRENIC, an epithet applied to parts belonging to the diaphragm, as the nerve, artery, &c. See Nerve and Artery.

PHRENITIS, in *Medicine*, from φρην, *the mind*, fometimes written *phrenefis*, *a phrenfy*, or a diforder of the underftanding, (*fapientiæ ægritudo*, as Pliny denominates it, Hift. Nat. lib. vii. cap. 51.) has been underftood, however, in a limited fenfe from the time of Hippocrates; namely, as a continued ferocious delirium, accompanied by an acute fever, and arifing from inflammation of the brain, or its membranes. In the language of modern nofologifts, *phrenitis* fignifies literally *inflammation of the brain*; the termination *itis* implying inflammation of the organ alluded to, as in *hepatitis*, *enteritis*, &c.

Some writers derive the word from φρενες, *the diaphragm*, in which organ the mind was anciently fuppofed to be feated. See Paraphrenitis.

The fymptoms which characterife acute inflammation of the brain are a vehement fever, a violent deep-feated pain in the head, a rednefs and turgefcence of the face and eyes, intolerance of light and noife, continued watchfulnefs, and an impetuous and fierce delirium. (Cullen, Firft Lines, § 293.) Some writers, indeed, have attempted to eftablifh a diftinction, as in the inflammations of other vifcera, between the affections of the invefting membranes, and of the fubftance of the brain; and have maintained that the fymptoms juft enumerated were peculiar to inflammation of the membranes, whilft fome degree of coma, inftead of wakefulnefs,

fulnefs, characterifed the inflammation of the cerebrum itfelf. The fact is, in this, as in other vifceral inflammations, that both parts of the organ are commonly involved in the difeafe; but it is probable that the fymptoms are more violent, in proportion to the predominant affection of the membranes; and more obtufe and chronic, as the malady prevails more extenfively in the parenchyma or fubftance.

But, in truth, the fymptoms of inflammation of the common fenforium, the centre of fenfation and voluntary motion, are not always fo fimple and uniform as the figns of a fimilar affection of other organs. The other parts of the body, which are fo intimately connected with the fource of the nervous power, and fome of which are linked to it by direct and particular fympathies, are neceffarily more or lefs involved in the derangements of the brain. Inftead of a mere local difeafe, therefore, this inflammation becomes more peculiarly a general affection of the fyftem. Hence it is juftly remarked by moft writers on the fubject, that pure idiopathic phrenitis is a very rare difeafe, at leaft in this climate; in other words, that the congeries of fymptoms, conftituting the nofological character of the local inflammation above laid down, very feldom occur without great modifications. It fometimes puts on merely the ordinary character of common continued fever, when diffection has demonftrated not only the exiftence of inflammation, but of fuppuration in the brain. Indeed fo common is its occurrence in this form, though to a lefs degree than is followed by the fuppurative procefs, that an ingenious writer has attempted to prove, that all idiopathic fevers are, in fact, cafes of inflammation of the brain (fee Clutterbuck on Fever); an opinion which we have difcuffed at length under its proper head. (See FEVER.) It is univerfally admitted, however, that, except where external mechanical violence has been fuffered, a pure idiopathic phrenitis is rarely obferved; but that a fecondary or fymptomatic inflammation of the brain, of a lefs determined character, is frequently the refult of other difeafes, and then partakes more of an atonic or paffive form; arifing, for inftance, during the progrefs of general fever from any caufe, or from metaftafis in gout, rheumatifm, eryfipelas, and other acute diforders. It is juftly remarked, indeed, by an intelligent writer, that whenever the velocity of the circulation is much increafed, there muft always be, from the nature of the circulation in the head, a tendency to this complaint, or to congeftion in the larger veffels: hence headache, fuffufion of face, inflammation of the eyes, bleeding from the nofe, and other fymptoms denoting preternatural diftenfion of the veffels of the head, are among the moft frequent fymptoms of continued fever of the more acute kind. Wilfon on Febrile Difeafes, vol. iii. chap. 6.

Hiftory of the Symptoms.—Phrenitis often makes its attack with a fenfe of fullnefs in the head, flufhing of the countenance, and rednefs of the eyes, the pulfe being full, but in other refpects natural. As thefe fymptoms increafe, the patient becomes reftlefs, his fleep is difturbed, or wholly forfakes him. Sometimes it comes on with tremors of the limbs, and intolerable pains of the hands, feet, and legs; fometimes with ftupor and rigidity of the whole body; and fometimes with anxiety, and a fenfe of tenfion in the breaft, which is often accompanied with palpitation of the heart. Sometimes, again, the ftomach is early affected, (by its clofe fympathy with the brain,) and naufea, and a painful fenfe of weight in that vifcus, fometimes heart-burn and vomiting, are among the earlieft fymptoms.

The pain in the head foon becomes confiderable, and fometimes very acute. The feat of it is various: fometimes it feems to occupy the whole head; fometimes, although more circumfcribed, it is deep-feated and ill defined; and, in other cafes, it is felt principally in the forehead or occiput. The rednefs of the face and eyes generally increafes with the pain, and there is often a fenfe of heat and throbbing in the head, the countenance acquiring a peculiar fiercenefs.

Thefe fymptoms, for the moft part, do not laft long, before the patient begins to talk incoherently, and to fhew other marks of delirium: fometimes, however, delirium does not come on till the fifth, fixth, or feventh day. It gradually increafes till it often arrives at a ftate of phrenfy. The face becomes turgid, the eyes ftare, and feem as if ftarting from their fockets, tears, and fometimes even blood, flowing from them; and the patient fometimes refembles a furious maniac, from whom he is principally to be diftinguifhed by the fhorter duration of his complaint.

We fhould, *à priori*, expect in phrenitis confiderable derangement in the different organs of fenfe, which fo immediately depend upon the ftate of the brain; and fuch is the fact. The eyes are incapable of bearing the light, and falfe vifion, particularly that termed *mufcæ volitantes*, or floating motes and flafhes of light feeming to dart before the eyes, are frequent fymptoms. The hearing is often fo acute, that the leaft noife is intolerable: fometimes, on the other hand, the patient becomes deaf; and it has been even obferved, that the deafnefs and morbid acutenefs of hearing fometimes alternate. Affections of the fmell, tafte, and touch, are lefs obfervable.

The pulfe is not always fo much difturbed at an early period, as might be expected from the violence of the other fymptoms, compared with what is obferved in idiopathic fevers. In many cafes, however, the fever runs as high as the delirium, and the pulfe is harder than in common fever; indeed the hard and fmall pulfe is often one of the beft diagnoftics of the complaint: it is fometimes, though rarely, intermitting. The refpiration is generally deep and flow, fometimes difficult, now and then interrupted with hiccup, feldom humid and frequent, which laft is a very unfavourable fymptom. The deglutition is often difficult, fometimes convulfive. The ftomach is frequently oppreffed with bile, which is an unfavourable fymptom; and complete jaundice, the urine and fkin being tinged yellow, fometimes fupervenes. Inftead of a fuperabundance of bile, however, there is fometimes a deficiency of it, which feems to afford even a worfe prognofis. The fæces being of a white colour, and a black cloud in the urine, have been regarded as fatal fymptoms. The black cloud in the urine is owing to an admixture of blood; when unmixed with blood, the urine is generally pale.

Among the moft unfavourable fymptoms of phrenitis the following may be enumerated; namely, tremors of the joints, convulfions of the mufcles of the face, grinding of the teeth, fudden changes of the colour of the face from florid to pale, involuntary tears, a mucous difcharge from the nofe, the urine being of a dark red colour, or yellow, or black, or covered with a pellicle, the fæces being either bilious or white and very fetid, profufe fweat of the head, neck, and fhoulders, paralyfis of the tongue, general convulfions, much derangement of the internal functions, and the fupervention of the fymptoms of other vifceral inflammations, particularly of peripneumony. If the delirium changes to coma, and the pulfe at the fame time becomes weak and the deglutition difficult, the approach of death may be generally expected.

With refpect to the *caufes of phrenitis*, we have already obferved that it is a rare difeafe in our temperate climate, but is more frequently obferved in warm latitudes. The

predif-

predifpofition feems to confift in the irritability of youth, and of the fanguine temperament, as well as in a paffionate temper of mind. The exciting caufes are fuch circumftances, internal and external, as tend to produce an accumulation of blood in the head; among which are the direct influence of a vertical fun in tropical climates, or long expofure to it in hot weather in more moderate heats, efpecially under great bodily exertions; violent fits of anger; intoxication; concuffion, fracture of the fkull, or other mechanical violence; long and intenfe exertion of the mind; certain narcotic poifons, miafmata, and perhaps contagion.

The appearances which are obferved on diffection after death vary confiderably in different inftances, according to the actual feat of the inflammation, and to the duration and violence of the difeafe. Sometimes the *dura mater* is found reddened by a number of extremely fine veffels, filled with florid blood, which pafs between it and the cranium; but this membrane, when inflamed, exhibits lefs of this crowded ftate of veffels than many other membranous parts, which are naturally more vafcular. Sometimes a layer of coagulable lymph is found adhering upon its under furface, like an adventitious membrane; and fometimes adhefions are formed to a confiderable extent between it and the other membranes of the brain. It is not unufual, when the dura mater has been inflamed, efpecially in confequence of fome external violence, for fuppuration to take place, and pus to be found covering a portion of the membrane. Inflammation of the *pia mater* is more difficult to diftinguifh for a contrary reafon; namely, that in its natural ftate it is crowded with a great number of minute veffels: when inflamed, however, thefe fmall veffels are much more numerous, are filled with a florid blood, and form by their anaftomofis a beautiful network: at the fame time, there is a ftronger adhefion between the under furface of the membrane and the brain than ufual. It very rarely happens, that any layer of coagulable lymph is formed in the inflammation of the *pia mater*, which is fo very common in that of the *pleura* and the *peritonæum*. When the *pia mater* is inflamed to a high degree, pus is formed, and is fometimes found diffufed over the whole furface of the brain. When inflammation has exifted in the fubftance of the brain, it is rarely found extended over any large portion of it, but is rather confined to one or more diftinct fpots. In this ftate of difeafe the inflamed portion becomes of a red colour, although this is feldom very intenfe. When cut into, the colour is found to arife from a great many fmall veffels, which are filled with blood; and the part inflamed has no peculiar hardinefs, but yields nearly the fame fenfation to the touch, as it would do in a healthy ftate. If the inflamed portion be upon the furface of the brain, the membranes in the neighbourhood are alfo commonly inflamed. Inflammation of the brain frequently advances to fuppuration, and abfceffes are formed in it. When thefe are of a large fize, the weight of the pus breaks down the ftructure of the neighbouring parts, and they look fimply as if they had been deftroyed, or very much injured by the preffure. When the abfceffes are fmall, there is an ulcerated appearance of the cavities in which the pus is contained. Portions of the brain become gangrenous occafionally, efpecially after violent injuries of the head; but this appearance is extremely rare, where inflammation of the brain has originated from any other caufe. See Baillie's Morbid Anatomy, chap. xxiv.

The cure of phrenitis muft be conducted upon the fame general principles as that of other acute vifceral inflammations; and from the particular importance of the organ inflamed, the antiphlogiftic and evacuant plan muft be purfued with the utmoft vigour and expedition.

Blood-letting is to be confidered as the principal dependence of the practitioner, and the more early it is employed, the more efficacious in general it will prove. It fortunately happens, that, in this complaint, the advantages of general and local blood-letting may be combined; inafmuch as a large quantity of blood can ufually be procured from the veffels immediately connected with the inflamed organ. When this advantage can be obtained, it fhould never be overlooked. It is advifable, therefore, to open the temporal artery, or the jugular vein, and to take a large quantity of blood, according to the violence of the fymptoms, and to the age and ftrength of the patient. Some authors recommend the opening of the artery, and fome (efpecially Dr. Cullen and Hoffmann) prefer the fection of the jugular vein. The frantic ftate of the patient fometimes renders either of thefe operations difficult, otherwife perhaps the choice is of little importance. We have feen a few inftances, in which a free bleeding from the temporal artery was followed by the moft fpeedy and permanent relief, where the phrenitis had followed intoxication and a metallic poifon. Dr. M'Bride recommends that the blood-letting be carried to the extent of producing fyncope or fainting; and when that effect follows, the relief is perhaps more generally complete; it is, however, rather a precarious rule of practice, and moft practitioners prefer the fafer mode of repeating the blood-letting at a fhort interval, than pufhing it fo far.

The effects of the blood-letting, in diminifhing the morbid determination of blood to the head, fhould be feconded by all other means in our power. The application of *cold* to the fcalp, fuch as wafhing it, after fhaving, with cold water, vinegar and water, or with æther and fpirits, (which laft produce a great degree of cold by their rapid evaporation) is often exceedingly beneficial. To affift in leffening the flow of blood to the head, the patient fhould be kept as near the erect pofture as can be borne. At the fame time, every irritation, efpecially thofe of light and noife, of which the inflamed fenforium becomes peculiarly fufceptible, fhould be carefully withdrawn. Some writers, efpecially of the old fchool, have recommended warm bathing to the lower extremities, and the application of blifters and rubefacients to them, for the purpofes of revulfion. But Dr. Cullen juftly regards them as very ambiguous remedies, which are likely to be productive of injury by increafing the general excitement of the circulation. It has been propofed to immerfe the trunk and limbs in the warm bath, while cold applications are made to the head; a practice of which the theory is ambiguous, and a fufficient experience has fcarcely been obtained to warrant the recommendation. *Blifters* have been generally applied over the fhaven fcalp, after the excitement has been fomewhat reduced by blood-letting; but, on the whole, the active abftraction of heat, by means of the cold and evaporating fluids, above-mentioned, feems to afford a more decided relief.

In addition to thefe direct means of diminifhing the inflammatory action in the head, the indirect effect, which is produced by copious evacuations from the bowels, obtained by the ufe of *purgatives*, is of great importance, and fhould be carefully attended to. Even fyncope itfelf has been produced by profufe evacuations from the inteftines, which implies the complete influence over the circulation in the brain, which fuch operations produce. The free ufe of cathartic medicines, therefore, fhould be reforted to in all cafes of phrenitis; and if a fpontaneous diarrhœa fhould fupervene, the practitioner will be careful not to check it.

As in all other cafes of inflammatory fever, every external fource of excitement fhould be carefully excluded; the apartment fhould be cool and well ventilated; the bed-clothes light; the food liquid and chiefly of milk and farinaceous matters; the drink aqueous, cold, and acidulated. Antimonial and neutral diaphoretics may be exhibited as medicine, with the view of keeping a foft and moift ftate of fkin, and diminifhing febrile action.

When phrenitis occurs as a fecondary affection in common fever, or by metaftafis, it feldom affumes that violent character which idiopathic phrenfy puts on; and confequently it demands a lefs vigorous treatment. Neverthelefs the principles of the treatment muft be the fame. The removal of the determination of blood to the head muft be attempted by the fame meafures, ufed in a more moderate degree. Thus the more local evacuants, fuch as bleeding by leeches applied to the temples, by cupping and fcarifying the neck, and the application of cold, and of blifters to the fhaven fcalp, muft be reforted to, and repeated according to the violence of the fymptoms. The bowels fhould be evacuated by moderate cathartics, and fimilar diet and regimen fhould be adhered to as in the more acute fpecies. And it fhould be cautioufly obferved, that, even fhould fymptoms of typhoid fever fupervene, yet while there is evident congeftion in the brain, with flufhed face, ferrety eyes, delirium, or coma, wine and all other ftimulants muft be withheld, as having a direct tendency to aggravate the fymptoms, and to accelerate the fatal termination of the difeafe. See Fever. See Wilfon on Febrile Difeafes, vol. iii. chap. 6. Cullen's Firft Lines.

PHRENSY, a violent delirium, originating from inflammation of the brain. See Phrenitis.

PHRETOMANORUM Urbs, in *Ancient Geography*, a town of Italy, in Samnium, of which Q. Fabius took poffeffion, according to Diodorus Siculus.

PHRICODES, from φρικη, *horror*, *fhivering*, in *Medicine*, a fever defcribed by the ancients, of a remittent, femitertian form, in which the paroxyfms are not only ufhered in by fhiverings, but accompanied by them through the greater part of their duration. See Galen, Comment i. in lib. i. Epidem.

PHRIDIESGAM, in *Geography*, a town of Ruffia, in the government of Viborg, on the N. coaft of the gulf of Finland; 60 miles W. of Viborg. N. lat. 60° 35′. E. long. 26° 34′.

PHRIXIUM, in *Ancient Geography*, a town of Afia, on the confines of the Colchide and Iberia, according to Strabo; who fays that, in his time, it was called Ideeffa, and that it was well fortified.

PHRIXUS, a town of Afia Minor, in Lycia. Steph. Byz.—Alfo, a port of Afia, in the Thracian Bofphorus, near its mouth in the Euxine fea. Steph. Byz.—Alfo, a river of the Peloponnefus, in Arcadia, which received the waters of the Erafinus, and ran into the fea between Temenium and Lerna, according to Paufanias.

PHROLICHINO, in *Geography*, a lake of Ruffia, in the government of Irkutfk; 60 miles N. of Bargazinfk.

PHRONTIS, a word ufed by Hippocrates as the name of a peculiar diforder of the general nature of the melancholy affections. In this cafe the patient, he fays, feels, as it were, a thorn pricking the abdominal vifcera; he is extremely reftlefs and uneafy, and always avoids light and company. He dreads being touched, and becomes timorous and afraid of every thing; he is molefted with troublefome dreams, and imagines that he frequently fees fpectres and frightful objects.

PHRUGUNDIONES, in *Ancient Geography*, a people of European Sarmatia, near the fource of the Viftula, between the Sulones and the Avarini. Ptolemy.

PHRURÆSUM, mountains of Africa, in the interior of Mauritania Cæfarienfis, S.E. of the mountains Malæthubolus. Ptolemy.

PHRURI, a people of Scythia, in the vicinity of the Cafpian fea.

PHRURIUM, a promontory on the S. coaft of the ifle of Cyprus, near Curtum, and N.E. of the promontory Curias. The term denotes a fortrefs.—Alfo, a town of India, on this fide of the Ganges, placed by Ptolemy in the interior of the territory belonging to the Arvarni.

PHRYGANEA, in *Entomology*, a genus of infects of the order Neuroptera. The generic character is, mouth with a horny fhort curved mandible; four feelers; three ftemmata; the antennæ are fetaceous, longer than the thorax; wings equal, incumbent, the lower ones folded. There are fifty-five fpecies, divided into two fections. The genus Phryganea confifts of infects, which, in point of habit or general appearance, bear a confiderable refemblance to fome of the Phalænæ, (which fee,) and particularly to thofe belonging to the divifion entitled Tineæ. They may be diftinguifhed from moths by their feelers, as well as by the ftemmata fituated at the top of the head. The Phryganeæ proceed from fix-footed aquatic larvæ of a lengthened fhape, refiding in tubular cafes, which they form by agglutinating various fragments of vegetable fubftances, particles of gravel, &c. Thefe cafes are lined within by a tiffue of filken fibres, and are open at each extremity. The included larvæ, when feeding, protrude the head and fore-part of the body, creeping along the bottom of the waters which they inhabit by means of fix fhort and flender legs; on the upper part of the back, in moft fpecies, is fituated an upright papilla or procefs, ferving as a kind of prop or ftay, preventing the cafe from flipping too forward during the time the animal is feeding. The perfect infects are feen in a fummer's evening floating in the air in large maffes, and are eagerly devoured by fwallows. The Phryganeæ are eafily diftinguifhed from the fmaller moths by their wanting the fpiral tongue.

A. *Tail with two truncate Briftles.*

Species.

Marginata. Wings immaculate; body brown, with yellowifh fpots on the head, fides of the abdomen yellowifh. It is a large infect, and found in Germany. The thorax is grooved on the back; briftles of the tail yellowifh, annulate with brown, and as long as the abdomen.

* Bicaudata. Wings reticulate; body brown, with a yellowifh line on the head and thorax. It inhabits this country and other parts of Europe.

* Nebulosa. Wings pale cinereous; body brown. It inhabits alfo this and other countries in Europe.

Viridis. Wings greenifh-hyaline, immaculate; body greenifh. This is a fmall infect, and inhabits Germany. The antennæ are green tipt with black; the head and thorax are green, the latter faintly margined with black; the abdomen and legs are greenifh.

B. *Tail without Briftles.*

Species.

* Reticulosa. Wings fub-ferruginous, reticulate with black; body black. An inhabitant of Europe, as is alfo the next.

* Striata. Wings teftaceous, with darker nerves.

Analis. Wings brown, with a white spot near the tail; the nape is covered with golden hair. Found in Sweden.

* Fusca. Upper wings brown, immaculate; legs yellow. An inhabitant of this and other countries in Europe.

Discoides. Wings brown, with a pale margin, and spots on the disk; the body is grey. It is found in Germany.

Pilosa. Wings testaceous, immaculate; the head and thorax hairy. This is a Swedish insect.

Pallipes. All the wings black, immaculate; the legs are pale. A native of Italy, and is very small.

Signata. Wings grey, spotted with yellow, the hind margin is striate with yellow.

* Grandis. Wings brown-testaceous, with cinereous spots. This is one of the largest of the European phryganeæ, usually measuring an inch or more in length, and having very much the general aspect of a phalæna; the upper wings are grey, marked by various darker and lighter streaks and specks, and the under wings are yellowish-brown and semi-transparent. The larva, which measures nearly an inch and three-quarters in length, is of a flesh-coloured grey, with brown head and legs, and inhabits a tube composed of pieces of bark, small fragments of grass-stalks, or other substances. Like other larvæ of this genus, it is known by the name of *Cadew-worm*, and is frequently used by anglers as a bait. When arrived at its full growth it fastens the case or tube to the stem of some water-plant, or other convenient substance, in such a manner as to project a little above the surface of the water, and casting its skin, changes to a chrysalis of a lengthened shape, and displaying the immature limbs of the future phryganea, which in the space of a fortnight emerges from its confinement.

* Varia. Wings varied with dark-grey and black, and spotted with white in the middle. This has been described and figured by Mr. Donovan. The legs are testaceous, and annulate with black.

Irrorata. Wings grey-brown, with numerous whitish spots and specks. It is found in South America. A specimen of it is in sir Joseph Banks's museum.

* Phalænoides. Wings white, with scattered black spots; the body is black. It inhabits the northern parts of Europe.

Flavicornis. Wings grey; abdomen greenish; antennæ and legs yellowish. It inhabits Kiel.

* Rhombica. Wings grey-brown, with rhombic whitish spots. This is a much smaller species than the *grandis*, and is of a yellowish-brown colour, with two obliquely transverse rhomboidic semi-transparent white spots on each upper wing; the lower wings being whitish, with a tinge of yellow-brown towards the upper edge. The larva is of a greenish-brown colour, and like that of the *grandis* is found in rivulets and stagnant waters. The larvæ of the phryganeæ in general feed not only on the smaller water insects, but on the spawn of fishes, and even on the young fry itself.

* Grisea. Upper wings clouded, with a black marginal spot. This is found in England and other European countries.

Atomaria. Wings pale-grey, with numerous black dots. This is a native of Kiel; is rather a large insect; the antennæ are yellowish; the head and thorax hairy; the body cinereous.

Fennica. Wings striate, cinereous, with a testaceous dot near the tail; the body is black; the antennæ are white at the base. It inhabits Denmark. The antennæ of this species are black at the tip.

Atrata. Black; wings immaculate; antennæ short. It inhabits France. The body is villous.

Notata. Upper wings yellowish-grey, with a brown marginal spot. It inhabits North America. A specimen is in the museum of sir Joseph Banks.

* Bimaculata. Wings brown, with a double yellow lateral spot. It inhabits Europe. The larva is found in a tapering cylinder, composed of sand and mud.

* Nigra. Wings black; antennæ twice as long as the body. It is found in the northern parts of Europe, as is the next.

* Azurea. Wings black; the hinder part violet. The lower wings are likewise obliquely violet.

Variegata. Wings brown, speckled with testaceous. It is found in divers parts of Germany.

* Bilineata. Wings brown, with two transverse white lines on each margin. It inhabits northern Europe.

* Interrupta. Wings black, with four white bands, the anterior ones are interrupted, the hind one is marginal and composed of dots. This is a native of our own country, as is the next. The body is black.

* Hirta. Brown; upper wings hairy; antennæ as long as the body. The antennæ are white, annulate with brown.

* Longicornis. Wings brown, with two darker waved streaks; antennæ are very long. It is found, as well as the next, in this country and other parts of Europe.

* Quatuor-fasciata. Black; wings testaceous, with four black bands; antennæ very long.

Punctata. Wings fringed, pale-yellowish, dotted with white; the abdomen is green. It is a native of Paris, and very much resembles a moth.

* Filosa. Wings rounded, brown, immaculate; antennæ thrice as long as the body. This is a native of England.

Tri-punctata. Wings fringed, cinereous, with three brown dots. It inhabits Saxony. The antennæ are longer than the body.

* Minuta. Variegated with brown and cinereous; feelers villous. It inhabits Europe.

Pusilla. Wings fringed, brown-testaceous; antennæ moderately long, annulate with white and black. It is a native of Italy.

Atrata. Black; wings whitish, with numerous black spots, and two bands. It inhabits Siberia.

Ciliaris. Black; abdomen with a white line on each side; the hind shanks paler; antennæ moderate. It is found in various parts of Europe, but not in England.

Wæneri. Cinereous; lower wings paler, the inner margin whitish and hairy. It inhabits Sweden, as does the next.

Albifrons. Black; wings with four white linear streaks on the outer part.

Flava. Wings reticulate with yellow; antennæ moderately long. This and all the following are found in some or other of the countries of Europe.

Umbrosa. Black; upper wings with yellowish clouds.

Saltatrix. Wings hyaline, with a green and white spot; the antennæ are longer than the body.

Virescens. Wings white, with ferruginous spots at the suture, and inflected margin; abdomen greenish; legs yellowish.

Argentata. Wings varied with brown and silvery, with a brown dot behind the middle at the anterior margin, and three at the posterior; the lower ones tipt with brown.

Fasciata. Wings pale-yellow, with four white bands, one entire, the others composed of spots.

STRIGOSA. Teftaceous; lower wings with a long white ftreak towards the tip.

MACULOSA. Wings brown, hairy, fpotted with white, two of the fpots folitary towards the tip at the outer margin.

LACINIOSA. Teftaceous; wings with three white bands united at the bafe, and each divided at the tip, with an oblique fpot in the middle.

ATOMARIA. Teftaceous; wings grey, with numerous whitifh folitary and confluent dots.

TESTACEA. Wings and body brown-teftaceous; lower ones whitifh.

INCONSPICUA. Brown; antennæ and fore-feelers long; wings grey, glabrous at the tip; legs yellowifh.

CILIATA. Black; wings fubteftaceous, fringed, the veins at the margin very much branched, the four fore-legs teftaceous.

ANNULATA. Brown; antennæ long, annulate with white; wings fringed at the inner and hind margins.

PHRYGANICUS, in *Botany*, a term ufed by Diofcorides, and many other of the ancient Greeks, to exprefs fuch herbaceous plants as have hard and woody ftalks; fuch are the garden-thyme, and feveral others of that kind. They alfo call thefe plants *xylodes*, ξυλωδες, and ξυλωιδεα ϖα.

PHRYGES, or PHRYX, in *Ancient Geography*, a river of Afia Minor. It difcharged itfelf into the Hermus, gave its name to Phrygia, and feparated this province from Caria, according to Pliny.

PHRYGI, a people of Illyria, in the vicinity of the Ceraunian mountains. Strabo.

PHRYGIA, a country of Proconfular Afia, concerning the name of which there are two different opinions: the one afcribing it to the country, whence it paffed to the people; and the other attributing it to the people, who gave it to the country. According to the former opinion fome have derived it from the river Phryges or Phryx (now Sarabat;) others from Phrygia, the daughter of Afopus and Europa, an etymology which is founded in mere fable. Bochart fuppofes, that this tract was called Phrygia from the Greek verb φρυγειν, to burn or parch, which, according to him, is a tranflation of its Hebrew name, derived from a verb of the fame fignification. This etymology bears relation to the nature of its foil, which was dry in many parts of it, and which, in its mountains, exhibited traces of volcanos. Another opinion afcribes the name of Phrygia to Phryges, the people who inhabited it; and it is faid that they had at a former period borne the name of Bryges or Breges; and thefe, according to Strabo, were the fame people: Herodotus fays, that whilft they remained in Europe they were called Breges, but after their paffage to Afia, their name was changed into Phryges.

With regard to the boundaries of Phrygia, Strabo informs us, that thofe of the Phrygians and Myfians were diftinct; but that it was fcarcely poffible to afcertain them. He adds, that the Trojans, Myfians, and Lydians, are all, by the poets, blended under the common name of Phrygians, which Claudian extends to the Pifidians, Bithynians, and Ionians.

Phrygia Proper, according to Ptolemy, was bounded on the north by Pontus and Bithynia; on the weft by Myfia, Troas, the Ægean fea, Lydia, Mæonia, and Caria; on the fouth by Lycia; and on the eaft by Pamphylia and Galatia. It lies between the 37th and 41ft degrees of N. lat., extending in longitude from 56 to 62 degrees. Phrygia is commonly divided into the *Greater* and *Leffer*, called alfo Troas; but this divifion did not take place till Troas was fubdued by the Phrygians; and hence it is more confidered by fome Roman writers as a part of Phrygia, than Bithynia, Cappadocia, or any other of the adjacent provinces. In fubfequent ages, the Greater Phrygia was divided into two diftricts or governments, one called Phrygia Pacatiana, from Pacatianus, who, under Conftantine, bore the great office of the præfectus prætorio of the eaft: the other Phrygia Salutaris, from fome miraculous cures faid to have been performed there by the archangel Michael.

This country, as well as the whole of Afia Minor lying in the 5th and 6th northern climates, was, in ancient times, highly celebrated for its fertility. It abounded in all forts of grain, being, for the moft part, a plain country covered with a deep rich foil, and plentifully watered by fmall rivers. In fome parts it furnifhed bitumen and other combuftible fubftances. Having large plains and pafture grounds, it was well ftocked with cattle. The air was anciently deemed very pure and falubrious, though it is now, in fome parts, thought to be extremely grofs, as a great part of the country lies in an uncultivated ftate. The moft remarkable cities in Phrygia Major were the following, *viz.* Apamea or Apamia, the metropolis of all Phrygia, till the above-mentioned divifion of Conftantine took place: this is commonly called Apamea Cibotos.—Laodicea, now Efkihiffar, feated on the banks of the river Lycus, not far from Apamea; the inhabitants of which carried on a very confiderable trade in wool, which was much admired for its foftnefs, and who were reckoned the moft wealthy people in Afia Minor. Laodicea was one of the feven churches mentioned in the Apocalypfe; but at prefent only its ruins are to be feen. At Efkihiffar, as it is now called, there are ftill to be feen four theatres of white marble, as entire as if they had been lately built; near one of them is an infcription in honour of the emperor Titus.—Hierapolis, famous for its mineral waters, which, according to Strabo, when expofed to the air, petrified in the fpace of a year, and yet poffefs fuch a virtue as to render the fields watered by them to be exceeding fruitful, and to afford a prefent remedy againft innumerable diftempers. Near this city was a deep cavern, which was always overfpread with a thick fog, and which exhaled fuch a peftilential ftream, that it ftifled any living creature who approached it. Strabo and Pliny except the Galli or eunuchs of Cybele; Ammianus and Dio Nicæus except all eunuchs. Hierapolis is now called Bambuk-kalafi, and fome veftiges of its ancient magnificence may be ftill feen in heaps of ruins and fine pillars.—Gordium, fituated on the borders of Phrygia towards Cappadocia.—Coloffe, now Chonos, on the S. fide of the Meander.—Sipylus, the refidence of king Tantalus, and hence called Tantalis.—Synnada, noted for its marble quarries; built by Conftantine the Great, and declared the metropolis of Phrygia Salutaris, after his divifion took place. Befides thefe, and other cities of lefs note, there were fome in later times of no fmall account; fuch as Saqua, Chara-Chifar, Cillexuga, Einegiol, &c. taken by the Ottomans from the Chriftian princes, at the firft rife of the Ottoman empire.

The rivers of this country are the Mæander, now Madre or Mendre, which rifes in the hill Celænæ, paffes through Phrygia, divides Caria from Lydia, and after, as it is faid, 600 windings, by which it feems to flow back to its fountain-head, empties itfelf into the Archipelago between Priene and Miletus.—Marfyas, rifing near or at the fpring of the Mæander, and rufhing down from a confiderable height between rugged rocks, and after flowing through the town of Celænæ, in the fame channel with the

the Mæander, feparating into two branches, which form thefe two rivers; Marfyas purfuing a direct courfe with an incredible rapidity, and near Apamea being again received into the Mæander. Sangarius or Sangaris, fpringing from the hill Dindymus, wafhing Phrygia and Bithynia, and difcharging itfelf into the Black fea.—Phryx or Phryges, (which fee.)—Hermus, celebrated by the poets for its gold fands, which rifes near Dorylæum, and falls into the Archipelago near Smyrna.—Myfias, Orga, Olrima, &c.

The Phrygians claim high antiquity; but their origin is uncertain. Jofephus and St. Jerom fuppofe that they are defcended from Togarmah, one of the fons of Gomer. Herodotus, Strabo, Pliny, and Euftathius deduce their origin from the Brygians, a people of Macedonia, who, paffing into Afia Minor, were called Phrygians. Bochart agrees with thofe who trace their origin to Gomer, the eldeft fon of Japhet. Whatever was their origin, they were fuperftitious, voluptuous, and effeminate, without prudence, and fo fervile in their temper, that they could be induced to comply with their duty only by ftripes and ill ufage. This character, under which they are defcribed, gave rife to feveral trite and well-known proverbs: "Phryges feró fapiunt;" "Phryx verberatus melior;" &c. Their mufic was fuited to their effeminate temper, and tended, as fome have faid, to enervate the mind. The Phrygians are faid to have been the firft inventors of divination by the finging, flying, and feeding of birds. Their government was monarchical, and they were for fome time under one fovereign. But fome time before the Trojan war, this country was divided into feveral petty kingdoms, and feveral princes reigned at the fame period. Apollodorus mentions a king of Phrygia, who was contemporary with Ilus, king of Troy. Cedrenus and others fpeak of Teuthrans, king of a fmall part of Phrygia, whofe territories were ravaged by Ajax, and his daughter Tecmaffa carried away captive by the conqueror. Homer mentions Phorcys and Afcaneus, both princes and leaders of the Phrygian auxiliaries, that came to the relief of Troy. Tantalus was king of Sipylus, and he is faid to have been no lefs famous for his great wealth, than infamous for his avarice, and other deteftable vices. It is alfo reported, that with a view of appeafing internal difcords, the Phrygians confulted an oracle, which directed them to commit the government to a king; upon which they placed Gordius on the throne.

As to their commerce, we merely know, that Apamea was the chief emporium of all Afia Minor, which was the place of refort for merchants and traders from all parts of Greece, Italy, and the neighbouring iflands. From Syncellus we alfo learn that the Phrygians were for fome time mafters of the fea, and none but trading nations ever prevailed in that element. The country produced many rare and ufeful commodities, which afforded confiderable exports. They had a fafe coaft, convenient harbours, and other advantages which warrant our concluding that they carried on a confiderable trade. Of their laws we have no knowledge; and in favour of their learning it may be alleged, that, as they enjoyed the fovereignty of the fea, they muft have had a competent fkill in geography, geometry, and aftronomy; to which we may add that they had a more than ordinary knowledge of mufic.

It has been the opinion of fome writers, that the Phrygian language bore a great refemblance to the Greek, but others have alleged to the contrary. The few Phrygian words which have been tranfmitted to us, are carefully collected by Bochart and Rudbeckius. Strabo alfo fays, that it is difficult to difcover any fimilitude between the barbarous words of the Phrygian language and the Greek. The Egyptians looked upon the Phrygian tongue as the moft ancient language of the world: but other nations, and particularly the Scythians, will not admit this fact.

The ancient Phrygians were much addicted to fuperftition. They had many idols: but their principal deity feems to have been Cybele. (See CYBELE.) They alfo worfhipped feveral other idols, *viz.* Bacchus, Adagyus, and the Cabiri. In folemnizing the feftivals of their gods, and on other occafions, they had dances and fongs, which they called "lityerfes," from Lityerfes, fon of Midas, king of Phrygia. Hefychius mentions certain Phrygian dances, called by him "bricigmata," derived without doubt from the word Bryges, the ancient name of the Phrygians.

The kings of Phrygia whofe names are recorded were, Nannacus, Annacus, or Cannacas, who is the firft king mentioned in hiftory, Midas, Marcis, Gordius, Gordius II., Otreus, Lityerfes, Midas II., Gordius III., Midas III., and Midas IV., with whom ended the royal family of Phrygia, which became a province of the Lydian monarchy, and continued in that ftate till Crœfus was conquered, and all Lydia was reduced by Cyrus.

PHRYGIA *Minor*, or *Leffer Phrygia*, was divided into two parts, the maritime, called "Hellefpontiaca," and the Mediterranean, termed "Epictetus." The former borrowed its namo from the Hellefpont, and extended along the coaft from the town of Percote to the promontory Lectum or Lecton, oppofite to the N. fide of the ifland of Lefbos. This part was properly called Troas, or Troia, though the Trojan kingdom extended from the river Afopus, to the banks of the Caicus, including not only Troas, but alfo the greater and leffer Myfia. Epictetus, or the inland part of Phrygia Minor, extended to the neighbourhood of mount Olympus, in the greater Myfia. This part at firft belonged to Prufias, king of Bithynia, who yielded it, by agreement, to Eumenes, king of Pergamus, whence it was called Epictetus, that is, acquired. However, thefe appellations are frequently confounded, and both attributed to Phrygia Minor.

Phrygia Minor lay between the 40th and 42d degrees of N. lat., and in longitude was of fmall extent. In general it may be faid, that Phrygia Minor, as comprehending both the Hellefpontiaca and Epictetus, was bounded by the Propontis on the N., by the Ægean fea on the S., by Myfia Minor on the E., and the Hellefpont on the W. On the fea-coaft were the cities of Percote, Abydus, Arifba, Dardanum, Rhetum, Sigeum, Troy or Ilium, Lariffa, Colonæ, Alexandria, and Troas.

Of the rivers that watered Troas, or Phrygia Minor, we need only mention the Scamander and Simois, which fee refpectively. The only mountain of this country that deferves notice was mount Ida, being a ridge of hills extending from the city of Zeleia, near the borders of Myfia Minor, to the promontory Lectum.

The foil of this diftrict was anciently reckoned extremely fertile; and it has even now figns of fertility, though in a great meafure neglected and uncultivated. Modern travellers defcribe the Afiatic coaft of the Hellefpont, as a moft beautiful and fertile tract of land; the hills being covered with vineyards and olive plantations, and the vales productive of all forts of grain.

The inhabitants of Leffer Phrygia, or Trojans, fo called from Troy, the metropolis of that country, were undoubtedly a very ancient people; but authors are not agreed about their origin. Some reprefent them as by defcent Samothracians; others fay they were Greeks; fome again derive them from the ifland of Crete, whence they fuppofe Phrygia Minor

Minor to have been peopled; others fay, that they were defcended from the Arcadians, and there are writers who maintain that they originally came from Italy, in which opinion Virgil concurs.

Bochart thinks that Leffer Phrygia was planted by Afhkenaz, Gomer's eldeft fon, becaufe fome appellatives of lakes, rivers, iflands, cities, and men of that country, bear a refemblance to this name. But the blood of the firft inhabitants of this country, whoever they were, was mixed in procefs of time with that of foreigners, namely, of Myfians, Samothracians, Greeks, and Cretans, who fettled among them, and were reckoned of the fame defcent with the ancient proprietors.

As to their government, it was unqueftionably monarchical and hereditary; for from Dardanus to Priam, the father was conftantly fucceeded by the fon, or the elder brother by the younger. Their country was at firft parcelled out into feveral fmall kingdoms: but the fovereigns of all thefe were, in length of time, either expelled or made tributary by the Trojan kings; infomuch that Strabo enumerates nine fmall kingdoms, or principalities, fubject to Troy, befides the ifland of Lefbos. On this account the Trojan war was fo protracted; becaufe all thefe countries were to be fubdued before Troy could be invefted. Of their laws no particular fyftem remains. Their religion was fubftantially the fame with that of the inhabitants of Greater Phrygia. Their principal deities were Cybele, "the grand-mother of the gods," as they ftyled her, Apollo, Minerva, and Pallas, (fee PALLADIUM,) Venus, and Apollo Sminthius. The Trojans are celebrated as one of the moft polite and civilized nations of thofe days; and in the reigns of their later kings they rofe to a very confiderable pitch of fplendour and magnificence. Their language was probably the fame that was fpoken by the inhabitants of Greater Phrygia. Their trade can only be gueffed at from their fituation, which probably drew merchants from all the neighbouring parts to traffic in their country, as well for their own growth as for foreign productions. Their country abounded with the neceffaries of life, as we may conclude from their having fupported two very confiderable armies for many years. Their fettlements in Thrace, Peloponnefus, Sicily, Italy, Egypt, and Africa, afford fufficient proof, that they applied themfelves at an early period to trade and navigation, which, moft probably, were the fources of the riches, fplendour, and power, in which they far excelled all the neighbouring ftates.

Troas, or Phrygia Minor, was, in all probability, governed by kings before the reigns of Teucer and Dardanus; but the Trojan hiftory of that period is either fabulous or uncertain. Teucer, as fome fay, was the firft fovereign; he was the fon of Scamander and Ida, that is, born in Phrygia, near the river Scamander and mount Ida, and ruled over all Troas, or Phrygia Minor. From him the country was called Teucria; and the inhabitants were denominated Teucri. He was fucceeded by Dardanus, who extended the boundaries of his kingdom by confiderable acquifitions, and built two cities, one called Dardana, or Dardania, from his own name, and the other Thymbra, from Thymbræus, one of his intimates. Having reigned in Phrygia 64 or 65 years, he was fucceeded by his fon Erichthonius, who after a long, honourable, and profperous reign of 46, as fome fay, or according to others, 75 years, left the kingdom of Phrygia in a flourifhing condition. Tros, the founder of Troy, was his fucceffor, from whom Phrygia Minor borrowed the name of Troas, as its metropolis did that of Troy. He was fucceeded by his fon Ilus, who drove Tantalus out of Afia, and annexed his kingdom to the crown of Phrygia; and having enacted many ufeful laws for the regulation of public affairs, he died in the 40th year of his reign. On the death of Ilus, his fon Laomedon was placed on the throne; he built the citadel of Troy, but having treated Jafon and the Argonauts, who had landed on the coafts of Troy, in an inhofpitable manner, Hercules, who was one of them, avenged their caufe by taking Troy, and afterwards killing Laomedon. Podazers, his only furviving fon, was his fucceffor. In his reign happened the war which terminated in the capture of *Troy*, which fee; the city of Troy being utterly ruined, and moft of the inhabitants of Troas put to the fword. Some writers fay, that the neighbouring Phrygians and Lydians poffeffing themfelves of that country, fettled there; and that Troas from that time began to be called Phrygia; others are of opinion, that Æneas, having gathered together the fcattered remains of the Trojans, rebuilt the city; and that his defcendants, and the defcendants of Hector, reigned there till the country was fubdued by the Lydians, who became fo powerful as to over-run all Afia Minor. If the Trojans had any kings of their own, after their city was deftroyed by the Greeks, they probably made but an indifferent figure, fince they are not even named in hiftory. Anc. Un. Hift. vol. iii.

PHRYGIAN MODE, in *Mufic*. See *Grecian* MODE. This mode and its effects are fo frequently mentioned in ancient authors, that we muft collect into a point its pretended properties. The Phrygian mode is one of the principal and moft ancient modes of the Greek mufic. Its character was ardent, fierce, impetuous, vehement, and terrible. So that, according to Athenæus, trumpets and other military inftruments, founded in the Phrygian mode. All this, however, might be faid of our trumpets in founding the charge, fignals of battle, and even in playing marches; and that our kettle-drums and fide-drums are beaten in the Phrygian mode; in which all mufic feems at prefent tranfpofed by the eternal din of double drums and trumbone.

PHRYGIAN *Stone*, *Phrygius Lapis*, in *Natural Hiftory*, the name of a ftone defcribed by the ancients, and ufed in their time in dyeing; probably from fome vitriolic or aluminous falt contained in it, which ferved to enliven or fix the colours ufed by the dyers.

It was a light fpungy mafs, refembling a pumice, and the whiteft and lighteft were efteemed the beft. Pliny gives us an account of their preparing it for ufe for dyeing, which was by moiftening it with urine, and then heating it red-hot, and fuffering it to cool again: this calcination was repeated three times, and the ftone was then fit for ufe; and Diofcorides recommends it in medicine after burning; he fays it was drying and aftringent.

PHRYGIANS, PHRYGES, or PHRYGASTES, as St. Epiphanius calls them, in *Church Hiftory*, were a branch of the Montanifts; fo called from Phrygia, a country where they abounded.

They efteemed Montanus their prophet; and looked on Maximilla and Prifcilla as great propheteffes.

This fpirit of prophecy, or rather enthufiafm, was their diftinguifhing character. See CATAPHRYGIANS.

PHRYMA, in *Botany*, a Linnæan name, whofe meaning or derivation nobody has ventured to guefs, nor can we throw any light upon the fubject. Linn. Gen. 303. Schreb. 399. Willd. Sp. Pl. v. 3. 179. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 431. Juff. 117. Lamarck Illuftr. t. 516. Gærtn. t. 75. (Leptoftachia; Mitchell Eph. Nat. Cur. v. 8. 212.)—Clafs and order, *Didynamia Gymnofpermia*. Nat. Ord. *Perfonatæ*, Linn. *Labiatæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cylindrical,

drical, ftriated, gibbous at the bafe on the upper fide, two-lipped; its upper lip narrow, and longeft, with three awl-fhaped converging teeth; the lower obtufe, cloven. *Cor.* of one petal, ringent: tube the length of the calyx; upper lip fhorteft, nearly ovate, emarginate, ftraight; lower larger and more fpreading, three-cleft, the middle fegment moft prominent. *Stam.* Filaments four, two at each fide, the upper ones fhorteft; anthers roundifh, approximated, in the throat of the corolla. *Pift.* Germen oblong; ftyle thread-fhaped, the length of the ftamens; ftigma obtufe. *Peric.* none, except the permanent, furrowed, clofed calyx. *Seed* folitary, oblong, nearly cylindrical, with a furrow at one fide.

Eff. Ch. Calyx two-lipped, five-toothed. Seed folitary.

1. Ph. *leptoftachya.* Slender-fpiked Phryma. Linn. Sp. Pl. 838. Suppl. 277. Amoen. Acad. v. 3. 19. (Circææ foliis, amaranthi ficuli Boccone fpicâ, floribus parvis purpureis propendentibus, herba Floridana; Pluk. Amalth. 59. t. 380. f. 5.)—Leaves ovate, ferrated. Calyx of the fruit deflexed.—Native of clofe woods in North America; "from Canada to Carolina." *Michaux.* It is faid to have been fent to Kew in 1802, by the late Mr. Maffon, and is marked as a hardy perennial, flowering in July and Auguft. The herbage refembles a *Verbena* or *Veronica*, and the *flowers*, difpofed in long flender terminal fpikes, are too fmall and unattractive to obtain much favour. It is to be wifhed however that a good figure of fo little known a plant and genus might be given to the public.

2. Ph. *dehifcens.* Splitting Phryma. Linn. Suppl. 277. Willd. n. 2. (Buchnera cuneifolia; Linn. Suppl. 288. Willd. Sp. Pl. v. 3. 335. Thunb. Prodr. 100.)—Leaves wedge-fhaped, fharply toothed at the fummit. Calyx of the fruit erect, fplitting lengthwife. - Gathered by Thunberg at the Cape of Good Hope. (See BUCHNERA.) The younger Linnæus was not aware of having mentioned this plant under two different names, in his *Supplementum*, nor did Willdenow detect the miftake, though he juftly objected to its being a *Phryma.* We muft rely on Thunberg's authority in fuppofing it a *Buchnera.* The *ftem* is fhrubby, much branched, of humble growth. *Leaves* oppofite, ftalked, wedge or fan-fhaped, flefhy, rough with minute points or briftles; terminating in about feven ftrong fharp teeth. *Clufters* terminal, folitary, fimple, three or four inches long, of numerous *flowers*, which Linnæus the elder has very carefully defcribed on his fpecimen before us, as follows. "*Calyx* of one leaf, cylindrical, with five angles; abrupt, with five teeth; finally fplitting along one fide. *Corolla* of one petal; tube cylindrical; limb in five, nearly equal, fmall, rounded fegments. *Stamens* two long and two fhort. *Germen* fuperior, oblong; ftyle fhort; ftigma fimple. *Seed* (rather *capfule*) almoft as long as the calyx, obfcurely quadrangular, compreffed, fmooth, rugged in the upper part; abrupt at the bafe; of two cells. *Seeds* folitary, fomewhat club-fhaped." The fewnefs of the *feeds* is the chief objection to our confidering this plant as an indubitable *Buchnera.* Perhaps it ought to conftitute a new genus, but its habit clofely agrees with the Linnæan *Buchnera cernua*, an imperfect fpecimen of which is actually laid into the Linnæan herbarium as a nondefcript *Phryma.* We are unacquainted with the number of its *feeds.*

PHRYNICUS, furnamed *Arrhafius*, in *Biography*, a Greek fophift or orator, was a native of Bithynia, and flourifhed in the reigns of Marcus Antoninus and Commodus. Two works are attributed to him, *viz.* "Apparatus Sophifticus," and "Dictiones Atticæ." There is extant an abridgment of the latter, which was printed at Rome, with the title of "Eclogæ Nominum et Verborum Atticorum," Gr. et Lat. 1517. The beft edition of this work is that of Pauw in 1739. Of the fame name were a compofer of a tragedy, the difciple of Thefpis, and a comic poet, who flourifhed about a century later.

PHRYNIUM, in *Botany*, a name borrowed by Willdenow from the ancient Greeks, whofe φρυνιον was fo called from φρυνη, *a red kind of land toad*, reputed venomous, to which the plant in queftion, being armed with fpines, was thought to be hoftile. Our *Phrynium* is a fmooth herb, growing in damp fhady places, and rather affording fhelter to various reptiles, than dangerous to any. Willd. Sp. Pl. v. 1. 17. Rofcoe Tr. of Linn. Soc. v. 8. 341. (Phyllodes; Loureir. Cochinch. 13.)—Clafs and order, *Monandria Monogynia.* Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Brown Prodr. Nov. Holl. v. 1. 307.

Gen. Ch. *Cal.* Perianth fuperior, of three awl-fhaped, erect, equal leaves. *Cor.* of one petal, tubular; its limb in feven fegments; the three outermoft acute, nearly equal, reflexed; the four innermoft obtufe, erect, unequal. Nectary a long, channelled, upright lip. *Stam.* Filament folitary, awl-fhaped, fhort, united to the bafe of the nectary at one fide; anther oblong, irregular, fimple. *Pift.* Germen inferior, ovate, triangular; ftyle thick, fhort, fcarcely exceeding the ftamen; ftigma concave, bent towards the anther. *Peric.* Capfule bluntly triangular, of three cells. *Seed* folitary, ovate, fmooth.

Eff. Ch. Calyx of three leaves. Inner fegments of the corolla four, obtufe, unequal. Stamen awl-fhaped. Anther fimple. Style thick, fhort, inclined towards the anther. Capfule with one feed.

Obf. It appears by the defcriptions of authors, for we have not feen the fruit or germen, that the latter is of three cells, with the rudiments of three feeds, only one of which comes to maturity. Yet Willdenow mentions "three *nuts.*"

1. Ph. *capitatum.* Willd. as above. (Phyllodes placentaria; Loureir. Cochinch. 13. Naru kila; Rheede Malab. v. 11. 67. t. 34.)—Native of moift fhady places in Cochinchina China, and the coaft of Malabar. *Root* perennial, knotty, creeping horizontally. *Stem* none. *Leaves* radical, on long, fimple, upright fmooth *ftalks* four feet high, ovate-oblong, acute, entire, flat, fmooth, coriaceous, a foot long, obliquely furrowed. *Flowers* white, in a large feffile hemifpherical *cyme*, from a lateral cleft below the middle of the *leaf-ftalk*, accompanied by two large *bracteas*, embracing feveral fmaller ones, each common to many *flowers.* Loureiro obferves that the *germen* is generally abortive, and that the *leaves* are ufed for wrapping up cakes, in the oven, to give them an agreeable tafte as well as colour. The young unfolded *leaves* are infufed in rum or arrac, with thrice as much water, to make vinegar.

This may perhaps not be the only fpecies of its genus. We have two nondefcript plants gathered at Sierra Leone, by Dr. Afzelius, which that excellent botanift judged to belong to *Phrynium.* Their *inflorefcence* however feems to be terminal, and we are rather more inclined to refer them to *Thalia*, or perhaps *Maranta.*

PHRYNUM, in *Zoology.* See RANA *Bufo.*

PHTHALEON, in *Ancient Geography*, a town of Greece, upon the Pegafean gulf.

PHTHAS, in *Mythology*, a name given among the Egyptians to the Greek Vulcan, whom they confidered as the Supreme Divinity, or at leaft as an attribute of that active principle, or intelligent power, eternally united, in their opinion, with the chaotic mafs, by whofe energy the elements were feparated, and bodies were formed, and who continually prefides over the univerfe, and is the efficient caufe of all effects. For this we have not only the autho-

rity

rity of Plutarch (Isis et Osiris), who may be suspected of having exhibited the Egyptian philosophy in a Grecian dress, but the united testimony of many writers, who give such accounts of the Egyptian gods, Phthas or Vulcan, and Cneph or Agathodæmus, as render it probable that these were only different names expressing different attributes of the Supreme Divinity. The Egyptians, says Eusebius, call the maker of the universe by the name of Cneph, and relate, that he sent forth an egg from his mouth; which in their symbolical language denotes that he produced the universe. (See Cneph.) Diodorus Siculus (l. i.) speaks of the Egyptian Vulcan as the first king among the gods, and Manetho ascribes to him unlimited duration, and perpetual splendour. The name itself, Phthas, signifies, according to Jablonski, in the Coptic language, one by whom events are ordained, or the disposer of things. When the Egyptians mean to represent the ruler of the world as good, they called him by the appellation Cneph, denoting a good genius; and they represented him under the symbol of a serpent. Upon a temple dedicated to Neithas at Sais, the chief town in Lower Egypt, was this inscription; "I am whatever is, or has been, or will be, and no mortal has hitherto drawn aside my veil; my offspring is the sun." Plutarch and Proclus mention this inscription, though with some difference of language; and it is so consonant to the mythological spirit of the Egyptians, that notwithstanding the silence of more ancient writers, who treat of this theology, its authenticity may be easily admitted. If this be allowed, and if, at the same time, it be granted, as the learned Jablonski maintains (Pantheon Egypt.), that Neithas and Phthas were only different names for the same divinity, this inscription will be a strong confirmation of the opinion, that the Egyptians acknowledged the existence of an active intelligence, the cause of all things, whose nature is incomprehensible. On the obelisk of granite, transported from Egypt to Rome, amongst the hieroglyphics of which Hermaphion has given the interpretation, is the following remarkable passage, on the subject of Ramestas, king of Heliopolis: "This is he, whom Phtha, the father of the gods, has elected." These words, the father of the gods, point out the stars, which the Egyptian sages regarded as the most striking emblems of the divinity, and which the people really adored.

Upon the whole we may conclude, that Phtha was regarded, in remote antiquity, as the ordaining spirit, and the great architect of the universe. The inhabitants of Memphis raised a temple to him where he was principally worshipped. Herodotus and Diodorus Siculus have described this temple; and Suidas adds, the inhabitants of Memphis adore Vulcan under the name of Phtha. From Phtha we ought not to separate the god whom the Egyptians adopted under the name of Neith, since he also is the creating spirit. Neith, in fact, signifies, according to Jablonski, him who disposeth all things. By the first of these attributes, God was understood to be taken in a general sense, and by the second, his wisdom was particularly characterised. He had a temple at Sais; and Plato, who frequented it says, Neith, to whom the Greeks have given the name of Minerva, is its tributary deity. Neith and Phtha are therefore the same divinity. The Phœnicians, who received their religion and their knowledge from their brethren the Egyptians, likewise acknowledged Minerva, or Neith, for the artist of nature. Cadmus, the Phœnician, who carried this worship into Greece, gave the name of Neith to one of the seven gates of Thebes, in Bœotia; and there the Egyptian theology was taught. The Egyptians adoring the power of the creator under the name of Phtha, and his wisdom under that of Neith, honoured his beneficence, by calling him Cneph, or good, by way of excellence.

In fine we may conclude, notwithstanding what has been advanced to the contrary by Porphyry, and others, that it appears highly probable, that the ancient Egyptians acknowledged an active as well as a passive principle in nature, and as Plutarch asserts, worshipped τω πρωτω Θεω, the supreme deity. Brucker's Phil. by Enfield, vol. i. Savary's Travels in Egypt, vol. i.

PHTHEMBUTI, in *Ancient Geography*, a nome of Egypt, the capital of which was called "Tava" by Ptolemy.

PHTHENOTES, a nome of Egypt, the capital of which was Butos. Ptolemy.

PHTHIA, a port of Africa, in Marmarica, between the great Chersonesus and Paliurus.—Also, a town of Asia, in the vicinity of the Euxine sea.

PHTHINTHIA, a town situated in the interior of Sicily. Ptolemy.

PHTHIOTIS, a country of Greece, in Thessaly; it lay to the S.E. near Magnesia.

PHTHIRA, or Phthiro, a mountain of Asia Minor, in Caria. Steph. Byz. and Suidas.

PHTHIRIASIS, φθειρίασις, in *Medicine*, from φθειρ, *a louse*, signifies the lousy disease, *morbus pedicularis*, and *pediculatio*, of authors.

Of these well-known insects, which infest the human body, there are two species; the one more commonly affecting the hairy scalp, and the other the pubes. Of the former species, however, (the pediculus humanus,) there is a variety usually termed body-lice, concerning which Linnæus remarks, "Varietas capitis durior, coloratior, vestimentorum laxior, magis cinerea." These pediculi are bred abundantly among the inhabitants of sordid dwellings, of gaols, and work-houses, &c. and in such situations prey upon persons of all ages indiscriminately. There is, however, also a peculiar state of skin in people advanced in years, and connected with the disease, which has been denominated Prurigo senilis by Dr. Willan, in which they are generated, notwithstanding every attention to cleanliness or regimen, and multiply so rapidly, that the patient endures extreme distress from their perpetual irritation. The nits or eggs are deposited on the small hairs of the skin; and the pediculi are only found on the skin or on the linen, and not under the cuticle, as some of the old authors have represented. Many marvellous stories, indeed, are related by Forestus, Schenckius, and others, respecting lice bred under the skin, and discharged in swarms from abscesses, strumous ulcers, and vesications: and many individuals of great note are stated to have died, in ancient times, from the multitude of these devouring pediculi. Thus Plutarch relates of Sylla: "It was long before he perceived that he had an ulcer within his body; but at last the flesh putrefied, and produced such a quantity of lice, that though many persons were employed day and night in destroying them, yet they increased much faster than they could be removed; and to such a degree did the distemper prevail, that his clothes, baths, basins, and food, were polluted with that perpetual flux of corruption and vermin. He went many times in the day into the water, to scower and cleanse his body, but all in vain; the vermin multiplied so fast as to baffle every attempt to destroy them." The biographer adds, "it is said, that among the ancients, there died of this disease Acastus the son of Pelias, and nearer our own times Alcmæon the poet, Pherecydes the philosopher, Callisthenes the Olynthian, during the time of his imprisonment, and

Mutius

Mutius the lawyer: and if it be proper to add to thefe a perfon not diftinguifhed by any merit or virtue, Eunus, a fugitive flave, who was author of the war in Sicily, called the "fervile war," and who was taken and carried prifoner to Rome, died likewife of this ficknefs." (See Plutarch's Life of Sylla; alfo, Plin. Hift. Nat. lib. xxvi. cap. 13, who, fpeaking of phthiriafis, obferves, "quà Sylla dictator confumptus eft.) Herod, Ennius, and by fome Plato is faid alfo to have been deftroyed by the loufy difeafe.—In more recent times, Amatus Lufitanus has affirmed, that he was witnefs to the cafe of a gentleman, who perifhed miferably in this difeafe: "for fo univerfally did thefe infects fwarm over his body, that two negro fervants were entirely employed in collecting bafkets full from his perfon, and carrying them to the fea." Amat. Lufit. Contur. iii. Cur. 58. See alfo Foreft. Obf. Med. lib. viii. obf. 14. Johan. Schenck. Obf. Med. lib. v. obf. 2.

The mode in which pediculi are generated being now well afcertained, and fuch fatal fwarms of them being altogether unknown in modern experience, we can fcarcely give credit to thefe accounts. They are not only in all probability much exaggerated, but have actually originated in miftake. We have fhewn in a former article (fee INSECTS *infefting the human body*), that the *larvæ* or grubs of feveral winged infects, efpecially thofe of the common fly (Mufca domeftica, Linn.), and of the black beetle (Tenebrio molitor), not unfrequently breed, both in the internal paffages, and in external wounds, of the human body. And in warm climates, the flies are fo numerous about the perfons of the fick, that the utmoft care is requifite to prevent the generation of larvæ from the eggs which they depofit, not only in fuperficial wounds, but in the noftrils, mouth, gums, &c. fometimes even penetrating to the brain itfelf, and producing death. (See Dr. Lempriere's Obfervat. on the Difeafes of the Army in Jamaica, vol. ii. p. 182.) In the fame way maggots are fometimes generated in the patches of cutaneous eruptions, as defcribed by profeffor Murray of Göttingen in the cafe of leprofy. (See his Obf. de Vermibus in Lepra obviis. p. 25.—See alfo Bateman's Pract. Synopfis of Cutaneous Difeafes, p. 21. and Edin. Medical and Surg. Journal, for January 1811, p. 41.) From this view of the fubject, therefore, little doubt can remain, that the fatal cafes of antiquity, above alluded to, occurring in the warmer regions of Europe, were in reality cafes of ulceration, arifing from fcurvy or fome other cachectic condition, which afforded a nidus for the breeding of the maggots of flies, and were not true inftances of the morbus pedicularis.

The generation of lice, however, in connection with the prurigo of elderly people, though not fatal, is frequently a very troublefome and obftinate malady, and many external applications have been reforted to from ancient times to deftroy thefe loathfome and irritating parafites. But the deftruction of them is commonly a mere alleviation; fince their reproduction is extremely rapid. A decoction of the feeds of ftavefacre, or of the cocculus indicus, or the powder of either of thefe fubftances, alone or mixed with lard in the form of an ointment, are very effectual deftroyers of the pediculi of the head, and even of the body-lice. The mercurial ointments, fuch as that of the white precipitated oxyd, are alfo very efficacious in the fame inftances. For the *morpiones*, or crab-lice, as they are called from their round and flattened form, which fix themfelves firmly in the fkin, about the pubes, axillæ, and in fact on every part of the trunk and extremities where there is hair, are inftantly and completely deftroyed by inunction with the common blue mercurial ointment. The fpike-oil, as it has been called, which is the effential oil of lavender, mixed with oil of turpentine, has been deemed the moft efficacious poifon for thefe morpiones: its virtue depends perhaps principally upon the oil of turpentine, which is doubtlefs the moft ready inftrument of deftruction to all the infect tribe. Sir Edward Wilmot is faid by Dr. Heberden to have ufed, with complete fuccefs, in a cafe of morbus pedicularis, a compofition fomewhat fimilar to the fpike-oil; *viz.* of rectified oil of turpentine, and fpirit of wine, each four ounces, camphor fix drachms. A folution of the corrofive muriate of mercury in fpirit is alfo often efficacious in the pedicular prurigo of the body, and tends to remove the pruriginous affection of the fkin, which feems to give rife to the tendency to generate lice. It is to be obferved, however, as a matter of caution, that none of thefe pungent ftimulating fubftances can be applied to the fkin, without inflicting extreme pain, unlefs its furface be unbroken: for where the cuticle is abraded by fcratching, or by the breaking of puftules and veficles, or by the formation of rhagades or chaps, the irritation and fmarting excited by them is intolerable, and is followed by confiderable inflammation.

PHTHIRION, in *Botany*, a name ufed by fome authors for the *pedicularis*, or red rattle.

PHTHIROPHAGI, in *Ancient Geography*, the name of a people who inhabited the coafts of the Euxine fea. Mela.

PHTHISIS, in *Medicine*, from φθιω, *to corrupt*, fignifying corruption or *emaciation* in general, is commonly limited to that fpecies of emaciation, which arifes from a difeafe of the lungs; whence the epithet *pulmonalis* is ufually conjoined with it, denoting *pulmonary confumption*. See CONSUMPTION.

PHTHUTH, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana. Ptolemy.

PHU, in *Botany*, a name by which fome authors call the great garden valerian.

PHUCAGROSTIS, φυκαγρωστις, from φυκος, *a fea-weed*, and αγρωστις, *grafs*, a name which has been applied to the *Zoftera*, or Grafs-wrack. Cavolini, an eminent Neapolitan naturalift, has given it a temporary adoption, to diftinguifh one of the genera, of which he has found feveral confounded under *Zoftera*. His *Phucagroftis* is, however, well fhewn by Mr. Konig, in Ann. of Bot. v. 2. 92, to be itfelf the true Linnæan *Zoftera*; and the name is, moreover, inadmiffible, as being compounded of two already eftablifhed, *Agroftis* and *Fucus*; in which refpect it is no lefs faulty than the *Calamagroftis* of fome writers.

PHUMANA, in *Ancient Geography*, a town of Afia, in Babylonia, in the vicinity of Arabia deferta, according to Ptolemy, who marks it between Chuduca and Coefa.

PHUPHAGENA, a town of Afia, in Leffer Armenia, in the interior of the country towards the mountains between Arana and Mardara, according to Ptolemy.

PHUPHENA, a town of Afia, in the interior and near the mountains of the Leffer Armenia, between Ifpa and Arana, according to Ptolemy.

PHUSIANA, a town of Afia, in the interior of Affyria, between Gomara and Ifone, according to Ptolemy.

PHUSIPARA, a town of Afia, in Leffer Armenia, between Cienica and Eufimara. Ptolemy.

PHUT, a country and river of Africa, in Mauritania Tingitana. Pliny.

PHYCIS, in *Ichthyology*, the name of a fpecies of blennius, called *tinca marina*, or fea-tench: the leffer hake of the Britifh zoology.

PHYCIS is alfo a name given by Artedi, after Ariftotle, Pliny, and the reft of the ancients, to a fifh nearly allied to to the genus of the *blenni*, and called by fome *trebius* and *fuca;* and, according to Rondeletius, the *tinca marina* of the Italians. Salvian, however, denies that it is the tinca marina, and the matter is yet undecided among the writers on this fubject.

PHYCITES, in *Natural Hiftory*, the name given by the ancients to a ftone which had the impreffion of a fea-plant of the fucus or alga kind; probably in the manner in which our black coal flate is frequently found to contain the impreffions of fern and other vegetables.

PHYCTEUM, in *Ancient Geography*, a town of Greece, in the Peloponnefus.

PHYCUS, a promontory and fortrefs of Africa, in Cyrenaica, between Aptuchi Fanum and Apollonia. Ptolemy.

PHYCUSSÆ, iflands of Libya. Steph. Byz.

PHYGELA, a town of Afia Minor, in Ionia. Mela and Pliny.

PHYGETHLON, in *Surgery*, a carbuncle, or a phlegmon attended with confiderable heat, pain, rednefs, &c.

PHYLA, in *Botany*, a genus of Loureiro's, named by him from φυλη, *a tribe*, or *company*, becaufe a confiderable number of flowers are produced from one common calyx. Loureir. Cochinch. 66.—Clafs and order, *Tetrandria Monogynia*.

Gen. Ch. *Common Calyx* ovate, imbricated, of numerous, crowded, fpatulate, pointed leaves, containing many flowers. Perianth inferior, of two lanceolate, concave, erect leaves. *Cor.* of one petal, tubular, irregular; limb fhort, fpreading, in four nearly equal fegments, the uppermoft emarginate. *Stam.* Filaments four, fhort, in two rows below the mouth of the tube; anthers roundifh, two-lobed. *Pift.* Germen fuperior, roundifh; ftyle fhort; ftigma thickifh. *Peric.* none. *Seeds* folitary, naked, covering a thread-fhaped, naked, common receptacle.

Eff. Ch. Common calyx imbricated; proper of two leaves, inferior. Corolla four-cleft, irregular. Anthers roundifh, within the tube. Seed folitary.

1. Ph. *chinenfis*.—Native of China, where it is called *Lien fuen*. The *ftem* is herbaceous, annual, creeping, with afcending branches. *Leaves* oppofite, ovato-lanceolate, pointed, fmooth, ferrated towards the point only. *Flower* pale violet, lateral, on a long folitary ftalk. The author fufpected an affinity between this plant and *Protea*, guided, as it feems, by the artificial characters only, by which many an honeft man, fetting a falfe ftep in the beginning, has, like Gulliver's Laputian mathematicians, been led widely aftray. Nothing indeed can lefs accord with *Protea*, than the plant indicated by the above defcription, which we ftrongly fufpect to be no other than *Verbena nodiflora!* In that cafe however the *feeds* fhould have been defcribed two to each *flower*.

PHYLACA, in *Ancient Geography*, a place in the Peloponnefus, where is the fource of the river Alpheus. Paufanias.—Alfo, a town of Epirus, in the Moloffide. Livy. —Alfo, a town of Macedonia, in Pieria. Ptolemy.

PHYLACISTÆ, among the *Ancients*, officers to whofe keeping the flaves in prifons and work-houfes were committed.

PHYLACTERY, φυλακτηριον, fignifying a *memorial* or *prefervative*, in *Ecclefiaftical Hiftory*, a flip of parchment, wherein was written fome text of holy fcripture, particularly of the Decalogue; which the more devout people among the Jews inclofed in leather cafes, and bound with thongs on the forehead, and on the left arm. (See FRONTAL.) On thefe phylacteries were written thirty paffages out of Exodus and Deuteronomy. The phylacteries for the head had four cavities, into each of which was put one of the four following fections of the laws, *viz.* Exod. xiii. 1—10. Exod. xiii. 11—16. Deut. vi. 4—9. Deut. xi. 12—13. The other has but one cavity, and into that four fections are put.

They derived their name from φυλαττω, *I keep*, either becaufe they were fuppofed to preferve the law in memory, or rather, becaufe they were looked upon as a kind of amulets or charms to keep them from danger. They were called תפלין, *tephillin*, by the Jews. The Pharifees, in order to maintain an appearance of greater fanctity, or to attract notice by their oftentation, wore broader phylacteries, and larger fringes to their garments than the reft of the Jews. (Matt. xxiii. 5.) Some authors have inferred from Exod. xiii. 9. and Deut. vi. 8. that thefe phylacteries were of divine inftitution. But thefe paffages may be taken in a figurative fenfe, as they are by the Caraites, who wear no phylacteries at all. In our Saviour's time, however, they were worn by the Jews in general, by the Sadducees, who received only the law, as well as by the Pharifees, but with this difference, that thofe of the latter were larger than the others.

PHYLACTERY, in the general, was the name given by the ancients to all kinds of charms, fpells, or characters, which they wore about them, as amulets, to preferve them from dangers or difeafes.

The primitive Chriftians alfo gave the name phylacteries to the cafes wherein they inclofed the relics of their dead.

PHYLARCHUS, φυλαρχος, among the Athenians. The phylarchi were magiftrates, who had each of them the government of a tribe committed to his charge; and their bufinefs was to take care of the public treafures belonging to each tribe, to manage all their concerns, and call them together as oft as any thing happened that required the prefence of the whole body.

PHYLATERIA, a name given by fome botanical authors to the *polium*, or poly-mountain.

PHYLICA, in *Botany*, an ancient Greek name, occafionally written either φυλικη or φιλυκη; but to what it properly belongs, commentators have not determined. Theodore Gaza fuppofed it our Holly, *Ilex Aquifolium*. It is acknowledged to have been a tree or fhrub with evergreen leaves, and poffibly the name may have originated from φυλλικος, *leafy;* in which fenfe it is well applied to the prefent Linnæan genus, confifting of fhrubs with very copious evergreen foliage.—Linn. Gen. 105. Schreb. 142. Willd. Sp. Pl. v. 1. 1108. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 19. Thunb. Prodr. 44. Juff. 381. Lamarck Illuftr. t. 127. Gærtn. t. 24.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Dumofæ*, Linn. *Rhamni*, Juff.

Gen. Ch. *Cal.* Common receptacle of the fructification fcaly, collecting the flowers into a difk. Perianth fuperior, of one leaf, in five deep fegments, turbinate, villous internally, permanent. *Cor.* none, except five minute, pointed, vaulted, converging fcales, one at the bafe of each fegment of the calyx. *Stam.* Filaments five, minute, under the five fcales; anthers fimple. *Pift.* Germen inferior, roundifh; ftyle fimple; ftigma obtufe. *Peric.* Capfule roundifh, three-lobed, with three cells and three valves. *Seeds* folitary, roundifh, gibbous at one fide, angular at the other.

Eff. Ch. Perianth in five deep fegments, turbinate. Scales five, covering the ftamens. Capfule inferior, of three cells. Seeds folitary.

All the known fpecies of *Phylica* are natives of fouthern Africa, chiefly about the Cape of Good Hope. Linnæus defines fix only in *Sp. Pl.* ed. 2, but the 14th ed. of *Syft.* *Veg.*

Veg. contains twelve. Willdenow has nineteen; Thunberg's Prodromus seventeen. The new edition of the Hortus Kewensis mentions twelve as cultivated in the gardens about London, most of them introduced by the late Mr. Masson. They are greenhouse shrubs, flowering for the most part in the winter or early spring, distinguished by a bushy heath-like habit; copious, minute, terminal, white or woolly *blossoms*; and small, simple, numerous, scattered, linear or ovate *leaves*, whose upper surface is of a dark or shining green, the under pale, hoary, or woolly. Their *footstalks* are short, and in one instance at least accompanied by a pair of awlshaped *stipulas*. As the species require no critical illustration, the following will be sufficient examples.

Ph. *ericoides*. Heath-leaved Phylica. Linn. Sp. Pl. 283. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 224. (Alaternoides africana, ericæ foliis, floribus albicantibus et muscosis; Comm. Hort. v. 2. 1. t. 1.)—Leaves linear, revolute, imperfectly whorled. Flowers woolly.—Miller, and Curtis after him, erroneously assert this species to be a native of Portugal, covering extensive tracts of ground about Lisbon, as heath does in England. It is not mentioned by Brotero, in his Flora Lusitanica, nor does any other writer speak of it but as a Cape plant, brought into England above seventy years ago, and still common in every greenhouse. The *stem* is very much and determinately branched. *Leaves* rather above half an inch long, crowded, spreading in every direction, bright green, somewhat hairy, linear-lanceolate, revolute, with a narrow hairy furrow beneath. *Flowers* in small terminal heads, conspicuous for the snow-white tufted woolliness which crowns their *calyx*, like what is seen on the *corolla* of a Leucopogon; see that article.

Ph. *bicolor*. White and yellow Phylica. Linn. Mant. 208. Willd. n. 3. (Ph. strigosa; Thunb. Prodr. 44?)—Leaves linear, revolute, hairy, scattered; woolly beneath. Flowers hairy, longer than the floral leaves.—Found in sandy ground at the Cape, but a stranger to our gardens. Twice as large in every part as the former, with which its habit and *foliage* otherwise nearly agree; but the pubescence of the *calyx* consists in long straight silky hairs, not opaque white woolliness, and the *flowers* are accompanied by numerous crowded floral leaves, densely clothed with similar, but tawny, hairs. We have seen no specimen of Thunberg's *strigosa*, and therefore follow Willdenow in citing him with a mark of doubt, though his specific character leaves scarcely any room for hesitation.

Ph. *stipularis*. Horned Phylica. Linn. Mant. 208. Willd. n. 9. Ait. n. 7. (Chamælea foliis angustis subtùs incanis, floribus capitatis muscosis; Burm. Afr. 117. t. 43. f. 2.)—Leaves linear, revolute. Stipulas acute. Segments of the calyx elongated, awl-shaped, externally woolly.—Introduced by Mr. Masson in 1786, but has not yet blossomed. This is distinguished by a pair of minute, awl-shaped, acute, brownish *stipulas*, situated rather within the insertion of the *footstalk*, as in the genus *Pultenæa*; and by the remarkably long woolly points of the *calyx*, which had induced Linnæus, at one period, to call the species *cornuta*.

Ph. *pinifolia*. Pine-leaved Phylica. Linn. Suppl. 153. Willd. n. 10. Ait. n. 8.—Leaves linear, flat on both sides, very smooth. Spikes panicled. Flowers smooth; each about as long as its solitary ovate bractea.—Native of lofty mountains. Remarkable for its great smoothness, and flat fir-like *leaves*. The smoothness and form of the minute *flowers* are such, that Burmann mistook it for a species of *Bæckea*, nor is its habit dissimilar from that otherwise very remote genus.

Ph. *buxifolia*. Box-leaved Phylica. Linn. Sp. Pl. 283. Willd. n. 13. Ait. n. 10. (Chamælea folio subrotundo subtùs incano, floribus in capitulum collectis; Burm. Afric. 119. t. 44. f. 1.)—Leaves ovate, scattered or ternate; downy beneath.—Common in collections, flowering most part of the year. The *leaves* are rather elliptical, pointed, almost an inch long, and half an inch wide; rough with points, and of a dark shining green, above; covered beneath with dense white wool. *Flowers* numerous, in little round terminal white heads.

Ph. *racemosa*. Racemose Smooth Phylica. Linn. Mant. 209. Willd. n. 18.—Leaves ovate, dotted, smooth, or slightly fringed. Spikes panicled. Flowers smooth; each about as long as its solitary heart-shaped bractea.—Found about ditches at the Cape, but not yet brought to England. The *flowers* and *inflorescence* nearly resemble *pinifolia*, insomuch that this species was likewise made a *Bæckea* by Burmann in his Prodromus. The short, broad ovate *leaves*, rough with minute dots, and often fringed with hairs, abundantly distinguish it from *pinifolia* and every other. The *branches* are hairy.

Phylica, in *Gardening*, contains plants of the shrubby, evergreen, exotic kind,—bastard alaternus,—of which the species cultivated are; the heath-leaved phylica (P. ericoides); the woolly-leaved phylica (P. plumosa); and the box-leaved phylica (P. buxifolia).

Method of Culture.—They are chiefly increased by cuttings and slips of the young shoots. In spring, as about March or April, a quantity of young cuttings, or slips of the small shoots, should be taken off, planting them in pots of rich earth, plunging them in a hot-bed, or in the bark-bed in the stove; giving frequent waterings, and occasional shade from the sun, when they will soon emit roots, and become proper plants fit for potting off separately in autumn: or the young cuttings or slips may be planted any time in summer, particularly in June and July, in pots as above, and placed under a hot-bed frame, or covered close with hand-glasses, being watered and shaded; when they will also grow, but not to be so forward as those of the spring planting.

These are somewhat tender plants, requiring shelter in winter in this climate: of course they must always be kept in pots, and placed among the greenhouse exotics, where they will effect a very agreeable variety at all seasons, and flower annually a great part of the autumn and winter, but do not produce seed in this climate.

PHYLITÆ, in *Ancient Geography*, a people of India, on this side of the Ganges; placed by Ptolemy with the Bittigi, near the river Nanaguna.

PHYLLACHNE, in *Botany*, received that appellation from Forster, in allusion to the slender chaffy aspect of its foliage and calyx, the word being derived from φυλλον, *a leaf*, and αχνη, *a husk*. Forst. Gen. t. 58. Linn. Suppl. 62. Schreb. 672. Mart. Mill. Dict. v. 3. Swartz in Sims and Konig's Ann. of Bot. v. 1. 286. t. 5. Juss. 422. Lamarck Illustr. t. 741. - Class and order, *Gynandria Diandria*. Nat. Ord. akin, at least, to the *Campanaceæ* of Linn. and Juss. See Forstera, with which genus Swartz has united the above-mentioned.

PHYLLAMPHORA, from αμφορευς, *a wine jar*, and φυλλον, *a leaf*, a name given by Loureiro, in his Cochinch. 606, to the Linnæan Nepenthes, see that article, in allusion to the pitcher-like appendage to the leaf. The author had a suspicion that his plant might be that of Linnæus, but he could not make it tally with the description. There is, however, no doubt of their identity.

PHYLLANTHUS, from φυλλον, *a leaf*, and ανθος, *a flower*, because the flowers, in one of the original species,

 grow

grow out of the leaves; but that fpecies is now a *Xylophylla.* Pliny has a *Phyllanthes*, of which we know enough only to prove that it is different from our's. Linn. Gen. 484. Schreb. 628. Willd. Sp. Pl. v. 4. 573. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 5. 333. Juff. 386. Lamarck Illuftr. t. 756. Gærtn. t. 108. Clafs and order, *Monoecia Monadelphia.* Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juff.

Gen. Ch. Male, *Cal.* Perianth of one leaf, bell-fhaped, coloured, in fix deep, ovate, obtufe, fpreading, permanent fegments. *Cor.* none, except the calyx be taken for fuch. *Stam.* Filaments united into a column; anthers three, two-lobed.

Female, on the fame plant, and in the fame fituation, as the male, *Cal.* Perianth as in the male. *Cor.* Petals none. Nectary a border with 12 angles, furrounding the germen. *Pift.* Germen fuperior, roundifh, with three blunt angles; ftyles three, fpreading, cloven; ftigmas obtufe. *Peric.* Capfule roundifh, with three furrows, three cells, and fix elaftic valves. *Seeds* folitary, roundifh.

Eff. Ch. Male, Calyx in fix deep fegments. Corolla none. Filament columnar. Anthers three.

Female, Calyx in fix deep fegments. Petals none. Nectary a border with twelve angles. Styles three. Capfule three-lobed, with fix elaftic valves.

Obf. Willdenow defcribes *Ph. obovatus* with fix anthers.

Much uncertainty has exifted, and does ftill exift, refpecting the plants that ftrictly belong to this genus. Linnæus has but fix fpecies in the 2d edition of Sp. Pl. and feven in the 14th ed. of Syft. Veg. He always confidered *Phyllanthus* as having three feparate ftamens, but this is certainly a miftake, at leaft as far as we have been able to examine. Willdenow has augmented the genus to 36 fpecies, and he wifhes to unite with it the whole of *Xylophylla*, Willd. Sp. Pl. v. 1. 1500, making feven fpecies more. We conceive the latter propofal to be inadmiffible, and thefe genera are kept diftinct in the recent edition of Hort. Kew. though placed next to each other in the *Monoecia Monadelphia.* This laft point will be confidered hereafter, when we come to Xylophylla. Nine fpecies of *Phyllanthus* are enumerated as cultivated in the Britifh collections, where they are moftly ftove fhrubs, chiefly remarkable for their delicate pinnate foliage, refembling fome *Mimofæ*, and turning red in decay. Many of them, however, have fimple *leaves.* The *flowers* are fmall, greenifh, axillary, copious, on fhort flender ftalks. Very few of the fpecies are figured in any botanical works, and none in our periodical ones. We fhall enumerate a few fpecies.

Ph. *obovatus.* Annual Carolina Phyllanthus. Willd. n. 3. Ait. n. 1. (Ph. carolinenfis; Michaux Boreal-Amer. v. 2. 209.)—Leaves fimple, obovate, bluntifh. Flowers axillary, ftalked, in pairs. Stem branched, round, erect. Native of North America. It was introduced in 1803 by Robert Barclay, efq. to whom the gardens are indebted for feveral of the more curious, though lefs oftentatious, American plants, overlooked by vulgar collectors and admirers. The prefent is a hardy annual, flowering in July and Auguft. *Stem* much branched. *Leaves* ftalked, alternate, not an inch long, entire, fmooth; bright green above; paler beneath. *Stipulas* fmall, membranous. *Flowers* fmall, greenifh, one male, the other female. *Capfule* fcarcely fo big as hemp-feed.

Ph. *bacciformis.* Berry-fhaped Phyllanthus. Linn. Suppl. 415. Willd. n. 25. Konig in Ann. of Bot. v. 1. 357. (Agyneia impubes; Venten. Jard. de Cels. t. 23; but not of Linnæus.) — Leaves two-ranked, elliptical. Branches two-edged. Flowers axillary; the upper ones female, folitary; the lower male, three together.—Native of Tranquebar. *Root* annual. *Stems* numerous, fpreading widely, befet with numerous leafy *branches. Leaves* broadly elliptical, hardly an inch long. *Stipulas* awl-fhaped. *Flowers* green. Mr. Konig has fhewn the miftake of M. Ventenat, in fuppofing this the true *Agyneia impubes* of Linnæus, who is thereby vindicated from the abundance of errors in the defcription, with which the learned, not uncandid, Frenchman rather too haftily charges him. The *Agyneia* in queftion is figured in the above Ann. of Bot. t. 7. f. 4.

Ph. *Emblica.* Shrubby Eaft Indian Phyllanthus. Linn. Sp. Pl. 1393. Willd. n. 36. Ait. n. 9. (Myrobalanus Emblica; Rumph. Amboyn. v. 7. 1. t. 1. Nilicamaram; Rheede Hort. Malab. v. 1. 69. t. 38.)—Leaves pinnate, bearing the flowers; leaflets oblong, rather acute; footftalks round, downy. Flowers aggregate. Stem fhrubby. Native of the Eaft Indies; long cultivated in our ftoves. No time for its bloffoming is marked in the Hort. Kew. but we had a flowering fpecimen from Mr. Salifbury's collection in 1788. The *leaves* are elegantly tinged with red. We can hardly believe them to be really pinnate and floriferous, but fhould rather confider as *branches*, what are termed their common *footftalks*, and from the lower part of which copious axillary tufts of little yellowifh *flowers* come forth. The *fruit* is as large as an ordinary goofeberry, and is figured under the name of *Emblica*, in Gærtner t. 108. It does not appear to be more pulpy than that of other fpecies.

Phyllanthus, in *Gardening*, furnifhes plants of the evergreen exotic tree and fhrubby kind: the fea-fide laurel, of which the fpecies cultivated are, the annual phyllanthus (P. niruri); the great-leaved phyllanthus (P. grandifolia); and the fhrubby phyllanthus (P. emblica).

Method of Culture.—Thefe plants, where feeds can be procured from their native fituations, may be raifed in that way. They fhould be fown in pots filled with light earth, and plunged in a hot-bed; and when the plants have acquired fome growth, they fhould be planted out into feparate pots filled with the fame fort of mould; being replunged in the hot-bed, due fhade and water being given, until they become perfectly rooted; after which they fhould be conftantly kept in the bark-bed of the ftove, and have the management of other plants of the fame tender fort.

They may alfo fometimes be raifed by planting out flips, or by layers managed in the fame way as thofe from feeds.

They afford a fine variety in their beautiful foliage, and the flowery kinds have a fingular effect in their flowers.

PHYLLAUREA, in *Botany*, a hybrid Greek and Latin name, from φυλλον, *a leaf*, and *aureus*, *golden*, given by Loureiro to the *Croton variegatum* of other authors, of which he makes a diftinct genus; Lour. Cochinch. 575. We greatly doubt the propriety of the meafure, and the name is certainly inadmiffible.

PHYLLEIUS, in *Ancient Geography*, the name of a country, a mountain, and a town of Macedonia.

PHYLLIREA, in *Botany*. See Phillyrea.

PHYLLIS is, by Linnæus, in his Philofophia Botanica, reckoned among the poetic names, familiar in ancient ftory, like *Hyacinthus*, *Narciffus*, &c. But in his Hortus Cliffortianus, he mentions having particularly chofen this appellation for the plant which now bears it, becaufe the beauty of the fhrub chiefly confifts in its leaves. *Phyllis* would have been more peculiarly appofite for any fhrub or tree producing an exuberant foliage fuddenly from naked branches, like the Almond, into which the unfortunate Thracian queen was fuppofed to be metamorphofed.

Linn. Gen. 126. Schreb. 177. Willd. Sp. Pl. v. 1. 1354. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 114. Juss. 198. Lamarck Illustr. t. 186. Gærtn. t. 25. Class and order, *Pentandria Digynia*. Nat. Ord. *Stellatæ*, Linn. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, obsolete, of two minute leaves. *Cor.* Petals five, lanceolate, obtuse, revolute, scarcely connected at the base. *Stam.* Filaments five, shorter than the corolla, capillary, flaccid; anthers simple, oblong. *Pist.* Germen inferior, obovate; style none; stigmas two, awl-shaped, downy, reflexed. *Peric.* none. Fruit oblong, somewhat turbinate, obtuse, angular. *Seeds* two, parallel, convex and angular at the outer side, flat at the inner, broader upwards.

Eff. Ch. Stigmas rough. Calyx of two leaves. Petals five. Seeds two.

Obs. Linnæus remarks that the stigmas resemble those of the grasses, the elm, and *Tetragonia*. He seems originally to have had, like Boerhaave, who called this plant *Bupleuroides*, an idea of its affinity to the umbelliferous order; but he has justly referred it subsequently to his *Stellatæ;* so that what regards the inflorescence in his Genera Plantarum is entirely misplaced.

1. Ph. *Nobla*. Bastard Hare's-ear. Linn. Sp. Pl. 335. (Valerianella canariensis frutescens, Simpla nobla dicta; Dill. Elth. 405. t. 299. Bupleuroides; Walth. Hort. 11. t. 6.)—Native of the Canary islands, where it is called *Simpla nobla*. It has been known for above a century in our gardens, where it is kept in the greenhouse, and flowers in June and July, but is valued rather for variety than beauty. The *stem* is shrubby, two or three feet high, with round smooth leafy *branches;* the lower part of a light corky aspect. *Leaves* opposite, on stalks, elliptic-lanceolate, acute, entire, smooth, two or three inches long. *Stipulas* between the footstalks, oblong, erect, strongly toothed and glandular, especially the upper ones. *Panicle* terminal, leafy, oblong, smooth, of numerous small green *flowers*. *Fruit* the size of a grape-stone.

This is the only known species of its genus, *Ph. indica*, Sp. Pl. 336, being struck out by Linnæus in his Mantissa altera, 349.

Phyllis, in *Gardening*, contains plants of the shrubby, evergreen, exotic kind, of which the species cultivated is the bastard-hare's-ear (P. nobla).

Method of Culture.—The plants may be increased by sowing the seeds in the early spring months, as about March, in pots filled with light earth, and plunged in a hot-bed; and when the plants have attained some growth, they should be planted out in separate pots, replunging them in the hot-bed, due shade being given till they become well rooted. In the summer season they should be set out in a sheltered situation, so as to have the morning sun, and be frequently watered. In the winter they must be well sheltered from frost, but have as much air as possible in mild weather.

In the second year, when the plants are shaken out of the pots and placed in a proper situation in the open ground, they flower better, and afford more perfect seeds, than when kept in pots.

They may also be raised by cuttings planted out in the summer season.

New plants should be raised every two or three years, as they do not last long.

They afford an agreeable variety among other evergreen plants of the greenhouse kind.

PHYLLITIS Marina, in *Natural History*. See Hart's *tongue*.

PHYLLOBOLIA, φυλλοβολια, in *Antiquity*, a custom that prevailed among the ancients to strew flowers and leaves on the tombs of the dead. The Romans adopted this custom from the Greeks, and added likewise wool. See Burial.

The phyllobolia was also used on occasion of a victory obtained at any of the public games; when not only the victors, but likewise their parents, were strewed with flowers and leaves.

PHYLLODES, in *Botany*. See Phrynium.

PHYLLOMA, so named by Mr. Ker in Curtis's Magazine, from φυλλον, *a leaf*, and λωμα, *a fringe* or *border*, alluding to the coloured toothed margin of the leaves. Ker in Curt. Mag. v. 38. 1585. Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Asphodeli*, Juss.

Gen. Ch. *Cal.* none. *Cor.* Petals six, oblong, nearly erect, equal, cohering by their claws; three of them internal. *Stam.* Filaments six, inserted into the receptacle, thread-shaped, erect, equal, rather shorter than the corolla; anthers oblong, incumbent. *Pist.* Germen superior, roundish, three-lobed; style awl-shaped; stigma simple. *Peric.* Berry tough, spherical, depressed, with three furrows, and three cells. *Seeds* numerous in each cell, in two rows, horizontal, oblong, angular, polished.

Eff. Ch. Corolla of six petals, erect. Filaments thread-shaped. Berry of three cells. Seeds numerous, angular.

1. Ph. *marginatum*. Aloe-leaved Phylloma. (Ph. aloiflorum; Curt. Mag. t. 1585. Dracæna marginata; Ait. Hort. Kew. ed. 1. v. 1. 454. ed. 2. v. 2. 277. Willd. Sp. Pl. v. 2. 157.)—The only known species, said to be a native of the island of Bourbon. M. Richard is mentioned as having sent it to Kew in 1766. There is a fine specimen of this plant in the stove at Chelsea, which flowers in the spring, and often ripens fruit. The *stem* is shrubby, several feet high, and probably forming, in its native country, a small and thick tree, with all the appearance of an arborescent *Aloe*. *Leaves* a yard long, succulent, smooth, taper-pointed, green, with a dull red, strongly toothed, or jagged, edge. *Common flower-stalk* axillary, compressed, similarly coloured, but not toothed, at the edges; *partial* ones alternate, round, spreading, red. *Flowers* numerous, racemose, each scarcely an inch long, of a tawny yellow. *Bracteas* solitary, taper-pointed, red. *Fruit* purplish-black, nearly the size and shape of a bullace plum.

The even *filaments*, and numerous *seeds*, well distinguish this, as a genus, from *Dracæna*. Its habit is like *Aloe*, but their characters are sufficiently different. We retain the excellent original specific name, as far preferable to *aloiflorum*, and certainly requiring no alteration.

PHYLLOS, in *Ancient Geography*, a country of the Peloponnesus, in Arcadia, according to Statius in his Thebaid.

PHYLLUS, a town of Thessaly, in which Strabo has placed a temple of the Phyllæan Jupiter.

PHYLOBASILES, φυλοβασιλεις, among the Athenians, magistrates, who, with respect to particular tribes, had the same office that the *basileus* had with respect to the commonwealth.

They were chosen out of the eupatridæ or nobility, had the care of public sacrifices, and other divine worship peculiar to their respective tribes, and kept their court in the portico called *basileion*, and sometimes in the *bucoleian*.

PHYMA, φυμα, from φυομαι, *to grow*, as plants from the earth, a term used by the ancients to denote almost every species of external and superficial tumour, arising without any obvious external injury. It comprehends, therefore, boils, glandular enlargements, cutaneous tubercles, and even large inflamed pustules, or small abscesses. See Galen; in in Comment. ad bib. vi. Epidem. Celſus, de Med. lib. ii. cap. 7.

Phyma, in *Surgery*, any ſuperficial inflammatory ſwelling, which quickly falls into a ſtate of ſuppuration.

PHYMOSIS. See Phimosis.

PHYRAMA, in the *Materia Medica*, a name given by ſome of the old writers to the gum ammoniacum, particularly to that part of it which was ſoft and ductile between the fingers. It is not clear that the gum ammoniacum of thoſe times was the ſame thing which we now know by that name; at leaſt it is certain, that the other kind of it, which they called *thrauma*, or *ammoniacum thrauſtum*, was not; for Dioſcorides deſcribes this as being of a reddiſh-brown colour, and very friable; and Avicenna ſays, that it marked a fine yellow or gold colour upon paper. Theſe are properties by no means agreeing with our gum ammoniacum; and if juſtly applicable to that, muſt prove that it could not be the ſame; and the characters given by Avicenna of its bitterneſs, and making a yellow ſtain upon paper, ſeem to make it the gamboge. This, however, by no means can agree with the other virtues attributed to it.

PHYSALIS, in *Botany*, φυσαλις of the Greeks, from φυσα, *a bladder*, an old name, applied by Linnæus to the *Alkekengi* of ſome preceding writers, the bladdery inflated calyx of which it well announces.—Linn. Gen. 99. Schreb. 134. Willd. Sp. Pl. v. 1. 1019. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 392. Brown Prodr. Nov. Holl. v. 1. 447. Juſſ. 126. Lamarck Illuſtr. t. 116. Gærtn. t. 131. (Alkekengi; Tourn. t. 64.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Luridæ*, Linn. *Solaneæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, ſwelling, ſmall, five-ſided, cut half way down into five pointed ſegments, permanent. *Cor.* of one petal, wheel-ſhaped; tube very ſhort; limb large, plaited, cut half way down into five broad acute ſegments. *Stam.* Filaments five, awl-ſhaped, very ſmall, converging; anthers erect, approaching each other. *Piſt.* Germen ſuperior, roundiſh; ſtyle thread-ſhaped, rather longer than the ſtamens; ſtigma obtuſe. *Peric.* Berry nearly globoſe, of two cells, ſmall, within the enlarged, inflated, cloſed, five-ſided, coloured calyx. *Receptacle* kidney-ſhaped, double. *Seeds* numerous, kidney-ſhaped, compreſſed.

Eſſ. Ch. Corolla wheel-ſhaped, plaited. Anthers converging, burſting lengthwiſe. Berry of two cells, within the inflated, angular, membranous calyx.

A genus of lurid, chiefly downy, viſcid and fœtid plants, almoſt entirely extra-european, whoſe fruit in ſeveral inſtances is eatable, though principally valuable only for an acidity, grateful in hot climates. The ſpecies are by no means clearly aſcertained, as many of them nearly reſemble each other, and few are cultivated except for curioſity; their vulgar dunghill aſpect, and rank growth, being hardly compenſated by the ſlight beauty of their flowers, or the ſingularity of the bladdery calyx. Linnæus has ten ſpecies in his Sp. Pl.; thirteen in Syſt. Veg. ed. 14. Willdenow reckons up ſeventeen, fourteen of which are mentioned in Hort. Kew. Mr. Brown has added one, from New Holland. Ten are perennial, and ſix of thoſe are ſhrubby; ſeven are annual, and very much branched.

In the firſt ſection are

Ph. *ſomnifera*. Cluſtered Winter-cherry. Linn. Sp. Pl. 261. Willd. n. 1. Ait. n. 1. Cavan. Ic. v. 2. 2. t. 103. (Solanum ſomniferum; Matth. Valgr. v. 2. 417. Ger. Em. 339.)—Stem ſhrubby. Branches ſtraight. Flowers crowded—Native of Mexico; naturalized, apparently, in Spain. It requires the protection of a greenhouſe in England, where it has been cultivated from the time of Gerarde to the preſent day, flowering in July and Auguſt. The whole plant is downy, of a pale dull green. *Leaves* ovate, entire, about an inch or two long, ſcattered, on ſhortiſh *ſtalks*. *Flowers* ſmall, pale and inconſpicuous, crowded among the leaves along the branches. *Fruit* ſcarlet, the ſize of a black currant, concealed by the greeniſh downy *calyx*. The bark of the *root* is ſaid to be a ſafe opiate, milder than opium.

The *Atropa fruteſcens* of Linnæus is ſo like this plant in habit, that he juſtly obſerves they can hardly belong to different genera; and Cavanilles has, we think not improperly, referred that *Atropa*, though ignorant of its being already deſcribed, to *Phyſalis*, by the name of *ſuberoſa*, in his Ic. t. 102. The *calyx*, though not cloſed, is ſufficiently inflated in its lower part to excuſe this meaſure.

Ph. *viſcoſa*. Clammy Winter-cherry. Linn. Sp. Pl. 261. Willd. n. 7. Ait. n. 6. Jacq. Hort. Vind. v. 2. 64. t. 136. (Alkekengi bonarienſe repens, baccâ turbinatâ viſcoſâ; Dill. Elth. 11. t. 10.)—Leaves wavy or toothed, obtuſe, ſlightly downy. Stem herbaceous; the upper part cymoſe. Fruit umbilicated, viſcid.—Native of the Braſils; a greenhouſe plant in England, but rarely kept, flowering in July. The *root* is creeping. *Flowers* of a very pale uniform yellow, without ſpots. *Berry* ſcarlet, covered with a viſcid fluid, and encloſed in a downy *calyx*.

Ph. *Alkekengi*. Common Winter-cherry. Linn. Sp. Pl. 262. Willd. n. 9. Ait. n. 8. Sm. Fl. Græc. Sibth. t. 234, unpubl. (Solanum Halicacabum; Matth. Valgr. v. 2. 416. Ger. Em. 342.)—Leaves two together, acute, nearly entire. Stem herbaceous, ſomewhat branched below. Root creeping.—Native of ſhady rocky places in the ſouth of Europe, very hardy in our gardens, where it ſpreads widely by means of its perennial creeping *roots*; flowering in June, but chiefly remarkable for its large, orange-coloured, permanent, drooping *calyces*, encloſing *fruit* of the ſame colour, and uſed for decorating many a ruſtic chimney-piece during winter. The *ſtems* are ſcarcely above 12 or 18 inches high. *Leaves* dark green. *Corolla* white. Dioſcorides ſpeaks of the berries as uſed, with other plants, to twine into garlands; and he records their medical qualities of curing the jaundice, and promoting the urinary ſecretion. For the latter quality they are celebrated in Lewis's Diſpenſatory, under the name of *Alkekengi*, though excluded from the more conciſe Pharmacopeia of the College.

Among the reputed annual ſpecies are,

Ph. *pubeſcens*. Downy Winter-cherry. Linn. Sp. Pl. 262. Willd. n. 12. Ait. n. 11. Brown Prodr. Nov. Holl. v. 1. 447. Fl. Peruv. v. 2. 41. (Ph. edulis; Sims in Curt. Mag. t. 1068. Alkekengi virginianum, fructu luteo, vulgò *Capuli*; Feuill. Peruv. v. 3. 5. t. 1. f. 2.)—Stem angular, much branched. Leaves heart-ſhaped, ſomewhat waved, downy. Flowers pendulous. Calyx-teeth ſharp. —Native of the warmer parts of America, but now naturaliſed in the Eaſt Indies, at the Cape of Good Hope, and even at Port Jackſon, New South Wales, where Mr. Brown informs us it is very plentiful, and known by the name of the Cape Gooſeberry, the berries being eaten, either raw, or in various articles of cookery. Dr. Sims ſpeaks of this fruit as agreeably acid and ſweet, with a fragrance like a mixture of apple and melon, and he ſays the plant is perennial and evergreen in a ſtove, though uſually reckoned herbaceous and annual. The *flowers* are pale yellow, with five large purple ſpots. The *calyx* of the *fruit* is nearly globular, ribbed, tawny. *Berry* yellow. This may be the ſame with the Linnæan *Ph. peruviana*, but we find nothing poſitive on that ſubject.

Ph. *parviflora.* Small-flowered Winter-cherry. Br. Prodr. Nov. Holl. v. 1. 447.—Stem angular, diffuse. Branches wavy. Leaves ovate, downy, nearly entire. Calyx-teeth acute. Seeds dotted.—Found by Mr. Brown in the tropical part of New Holland. *Root* annual. *Anthers* yellow.

Ph. *proſtrata.* Trailing Winter-cherry. L'Herit. Stirp. 43. t. 22. Willd. n. 17. Ait. n. 14. Andr. Repoſ. t. 75. Jacq. Ic. Rar. t. 38.—Stem procumbent, much branched, round, hairy. Leaves ovate, wavy, ſomewhat fleſhy.—Native of Peru, from whence it was brought by Dombey to the French gardens, and thence introduced amongſt us. It is a very tender annual, impatient of cold or wet while young, but in a hot dry ſummer it bears the open air, and is conſpicuous for a profuſion of delicate bright blue *flowers.* The *berry* is ſmall, dull purple, or brown.

Physalis, in *Gardening*, compriſes plants of the herbaceous and ſhrubby ornamental kind, of which the ſpecies cultivated are, the tooth-leaved winter cherry (P. angulata); the woolly winter cherry (P. pubeſcens); the common winter cherry (P. alkekengi); the Pennſylvanian winter cherry (P. penſylvanica); the clammy winter cherry (P. viſcoſa); the cluſtered winter cherry (P. ſomnifera); the flexuous Italian winter cherry (P. flexuoſa); the tree-like phyſalis, or winter cherry (P. arboreſcens); and the Curaſſavian winter cherry (P. curaſſavica).

In the firſt ſort there is a variety which is taller, with entire leaves, ſmaller flowers of a paler yellow colour.

Method of Culture.—All theſe plants are capable of being increaſed by ſeeds; the ſecond, third, fourth, and fifth ſorts, alſo by parting the roots; the ſixth, ſeventh, eighth, and ninth, likewiſe by cuttings.

In the firſt ſort, the ſeed ſhould be ſown in the early ſpring, as April, in pots of light earth, plunging them in a moderate hot-bed. When the plants have acquired a few inches in growth they ſhould be removed into ſeparate pots, gradually inuring them to the open air, in order that they may be removed with balls into the clumps or borders. But it is probably a better method to ſow them in the latter end of May in the places where they are to remain, as they do not bear tranſplanting well. They muſt be raiſed annually.

In the herbaceous kinds the ſeeds ſhould be ſown in the autumn as ſoon as they are ripe, or early in the ſpring, in the beds, borders, or clumps where they are to remain; or they may be tranſplanted into other beds to remain till the following autumn, when they may be removed to the ſituations where they are to remain.

The roots may be parted either in the early autumn or ſpring ſeaſon, when the weather is mild. The divided parts ſhould have root-fibres left at the bottoms and a bud in each at the tops in order to their ſucceeding properly.

In the ſixth and ſeventh ſorts, the ſeed ſhould be ſown in pots of light mould in the early ſpring and plunged in a mild hot-bed. When the plants have had a little growth they ſhould be pricked out into ſeparate ſmall pots, proper ſhade and water being given; being afterwards managed as the ſhrubby exotics of leſs tender plants.

They may likewiſe be raiſed from cuttings made in the latter ſpring or ſummer months, which ſhould be placed in pots of light mould and plunged in the hot-bed, due ſhade and water being given till they have ſtricken root.

And the two laſt ſorts may be raiſed from ſeeds or cuttings in the ſame way, by the aid of the bark hot-bed of the ſtove.

The firſt and the other herbaceous ſorts are curious ornamental plants in the borders, clumps, and other parts of pleaſure-grounds, and the four beſt ſhrubby ſorts in the greenhouſe and ſtove collections.

PHYSALUS, a name given by Rondeletius to a ſpecies of ſea-inſect, of the ſcolopendra marina kind, ſuppoſed by ſome to be the ſame with the ſcolopendra marina, or centipes, of the Iriſh ſea, deſcribed by Molyneux; but this does not appear to be the caſe, on a ſtrict enquiry. The phyſalus of Rondeletius has no mouth, whereas the ſea centipes of Ireland has a remarkably large one; that of Rondeletius is wider in the middle, and tapers at each end; but the Iriſh kind is largeſt at the head, and tapers from thence all the way to the tail. Rondeletius's has tubercles on the back, but the Iriſh one has only hairy ſtripes, and his is a poiſonous animal, whereas that of Ireland was found in the ſtomach of a cod-fiſh, which had eaten it as food. The figure given by Rondeletius agrees alſo very well with the account he gives, but not with the figure of that drawn upon the ſpot from the Iriſh fiſh, and given in the Philoſophical Tranſactions. On the whole, nothing is more plain than that theſe are two diſtinct ſpecies of animals, though of the ſame genus, Phil. Tranſ. N° 225. See Scolopendra.

Physalus, in *Zoology*, a ſpecies of Balæna, with a double opening to the ſpiracle on the middle of the fore-part of the head; and a ſoft fin on the hinder part of the back; the balæna, having three fins and a ſmooth belly, of Briſſon; the balæna, without teeth, having a narrow body and a fin on the back, of Ray; the phyſalus bellua, phyſeter of Geſner; the phyſeter of Pliny, Willoughby, and others; the finn-fiſke of Egede, &c.; the fin-whale of Pennant's Arctic Zoology; the fin-fiſh of the Britiſh Zoology; and the fin-backed whale of Dudley, Phil. Tranſ. abr. vii. 425. This fiſh inhabits the Atlantic both on the American and European coaſts. It is equal in length to the common whale, but not above a third, or even fourth part of the circumference, and produces much leſs blubber; the opening of the mouth is larger; the horny laminæ, or whale-bone, are ſhorter, and of a blueiſh colour. Its fleſh is better taſted; and it throws the water from the ſpiracles with greater force. The upper part of the body of this animal is of a clear brown colour, and the lower parts white; the lips are brown and reſemble a twiſted rope; on the lower part of the back, near the tail, there is a ſtraight, soft, ſharp-pointed fin, between three and four feet long, without rays or bones, from which circumſtance the Engliſh name of the ſpecies, to diſtinguiſh it from the common whale, having no back fin, is derived. From the violence with which this ſpecies throws out the water from its ſpiracle, it is ſuppoſed to be the Φυσαλος of the ancients. This ſpecies feeds on ſmall fiſhes of the clupea, ſcomber, and other genera. It is neglected by the whale-fiſhers, on account both of its great fierceneſs and the ſmall quantity of blubber which it affords: even its appearance in the whale ſeas is diſliked, as it is ſuppoſed to drive away the common ſpecies, which is ſo much in requeſt.

PHYSARUM, in *Botany*, a genus of *Fungi* in Perſoon's Syn. 168, whoſe ſpecies are by other writers referred either to *Trichia* or *Reticularia*. Bulliard has deſcribed ſome of them under the name of *Sphærocarpus*, which properly belongs to one of the *Hepaticæ*, as we propoſe to ſhew in its proper place. Perſoon's character of *Phyſarum* is as follows.

Caſe rigid, ſimple, moſtly ſomewhat rugged, and rather powdery. Threads internal, ſcattered, moſtly adhering like network to the caſe. He defines 16 ſpecies, all ſmall, found either on the trunks of trees, on the ground, or amongſt moſs.

PHYSCA, or Physce, in *Ancient Geography*, a town of the

the Lower Mœfia, between the mouths of the rivers Axiàcùs and Tyras. Ptolemy.

PHYSCÆ, a town of Macedonia, in Mygdonia, between Bærus and Terpillus. Ptolemy.

PHYSCELLA, a town of Macedonia, on the gulf Mecybernæus, according to Pliny and P. Mela.

PHYSCIA, in *Botany*, from φυσκη, *a bladder*, alluding to the concave or inflated receptacles, or fhields, of fome fpecies; fee LICHENES, n. 20.

PHYSCONIA, in *Medicine*, probably from φυσκη, *an inflated bladder*, a term ufed by the nofologifts to exprefs every fpecies of abdominal tumour, which is hard, not fonorous like tympanites, nor fluctuating like dropfy, nor produced by pregnancy. Under the appellation of Phyfconia a great variety of morbid enlargement in the abdomen is, therefore, neceffarily included; fuch as fcirrhous, fatty, and other tumours of the omentum, morbid growth connected with the ovaria, or uterus, with the inteftines or mefentery, with the liver, kidnies, &c. As thefe tumours are, in fact, extremely different in their nature and origin, the method of treatment appropriate to each can only be determined by an inveftigation of each variety; but it muft be acknowledged, that, as they refult from actual organic change in the ftructure of the parts difeafed, little that is effectually curative is within the reach of art. See Sauvages, Nofol. Meth. clafs x. genus 8.

PHYSCUS, in *Ancient Geography*, a town of Afia Minor, upon the coaft of the Doride, over-againft the ifland of Rhodes, according to Diodorus Siculus. Strabo fays that it had a port. It was called Phyfcia by Steph. Byz. and Phufca by Ptolemy.—Alfo, a port of Afia Minor, in Caria, N.E. of mount Loryma, W. of the promontory Pedalium. In this port there were a town and a river of the fame name.—Alfo, a town of Greece, in the country of the Locri Ozoli. Plutarch.—Alfo, a port of the ifland of Rhodes.—Alfo, a river of Afia, in the vicinity of Affyria.—Alfo, a mountain of Italy, in Magna Græcia, near Crotona.

PHYSETER, the *Cachalot*, in *Ichthyology*, a genus of animals of the clafs and order Mammalia Cete, of which the generic character is, teeth in the lower jaw, and none in the upper. The name phyfeter is of Greek origin, and is derived from the verb φυσαω, *to blow*. It has this name from its quality of taking in a great quantity of fea-water, and then blowing it out again with great force and violence. There are four fpecies in the Linnæan fyftem by Gmelin, which are as follow.

Species.

* CATODON; leffer Cachalot. It has no dorfal fin; but a fiftula or fpiracle on the fnout. It is about 25 feet in length; inhabits the Northern fea, and has been found on the coaft of Scotland. The head is round, and the mouth fmall. In its general ftructure is very nearly allied to the macrocephalus, to be next defcribed, but the mouth is fmaller.

* MACROCEPHALUS; blunt-headed Cachalot. This has no dorfal fin, but the fiftula is on the neck. This is one of the largeft fpecies of whales, often meafuring fixty feet. The head is of an enormous fize, conftituting more than a third of the animal; the mouth is wide; the upper lip rounded, thick or high, and much broader than the lower, which is of a fharpifh form, fitting as it were into a longitudinal bed or groove. The teeth that are vifible are fituated only in the lower jaw, and, when the mouth is clofed, they are received into fo many correfponding holes or cavities in the upper; they are numerous, rather blunt, and of a conical form, with a flight bend or inclination inwards. The front of the head is very abrupt, defcending perpendicularly downwards, and on its top, which has been improperly termed the neck by fome authors, is an elevation or angular prominence containing the fpiracle, which appears externally fimple, but is double within. The head is diftinguifhed or feparated from the body by a tranfverfe furrow or wrinkle. The eyes are fmall and black; and the ears or auditory paffages extremely fmall. About the middle of the back is a kind of fpurious fin or dorfal tubercle, of a callous nature, not moveable, and fomewhat abrupt or cut off behind. The tongue is of the fhape of the lower jaw, clay-coloured externally, and of a dull red within. The throat is fmall; the body cylindrical beyond the pectoral fins, growing narrower towards the tail. The colour of the whole animal is black, but as it grows old it becomes whitifh beneath. It fwims very fwiftly, and is faid to be a violent enemy to the white fhark. (See SQUALUS.) The Greenlanders ufe the flefh, oil, tendons, &c. in the fame manner as they do thofe of the Narwhal. (See MONODON.) This fpecies of whale is reckoned difficult to catch, being very tenacious of life, and furviving feveral days the wounds that it receives from its purfuers. It has a vaft cavity within the upper part of the head, in which fpermaceti is found. This, when frefh, is nearly fluid; but when expofed to the air it concretes into opaque maffes. The celebrated perfume ambergris is found in maffes in the inteftines, being the fæces of the whale when it is fick. (See AMBERGRIS.) The three varieties of this fpecies are; 1. Black; back gibbous. Found in European feas. 2. Blackifh-afh, with a gibbous back, which inhabits the coafts of New England, and is from fixty to feventy feet in length. 3. Whitifh, with a fmooth back. This laft is found in Davis's ftraits, is only about fifteen feet long, of a yellowifh-white; teeth a little incurvate, compreffed, rounded at the tips.

* MICROPS; Sharp-nofed Cachalot. The dorfal fin of this fpecies is long; and the upper jaw is longer than the lower. There are two varieties; in the *firft* the teeth are fharp and hooked; it is about feventy feet long, is of a dark tawny colour: has forty-two teeth round, a little compreffed; dorfal fin long and fharp: in the fecond the teeth are fharp and ftraight; this is from eighty to one hundred feet in length; the upper parts are blackifh, and beneath it is white; it has a high bunch on the upper part of the back; the fin is near the tail; the eyes are bright yellowifh; the tongue fmall and acute; the teeth are fet in the jaw like a faw. This fpecies fwims fwiftly, and is faid to be a great enemy to the porpoife, which it purfues and preys upon.

* TURSIO; High-finned Cachalot. This fpecies is particularly diftinguifhed by the great length and narrow form of its dorfal fin; the teeth are flat at the tip. This is faid to be fometimes one hundred feet in length; at a diftance the dorfal fin has the appearance of a maft of a fhip. It inhabits the Northern ocean.

PHYSIC, or PHYSICK, φυσικη, the art of healing, properly called *medicine*.

The word is formed from φυσις, *nature;* becaufe medicine confifts principally in the obfervation of nature.

For the rife, progrefs, divifion, &c. of phyfic, fee MEDICINE.

PHYSIC, *Hermetical*. See HERMETICAL.

PHYSIC, *Bachelor of*. See BACHELOR.

PHYSIC *Nut*, in *Botany*, the name of a fpecies of the jatropa. See CASSADA.

PHYSICAL, φυσικος, fomething belonging to, or really exifting in nature.

In this fenfe we fay, a phyfical point, in oppofition to a mathe-

mathematical one, which laft only exifts in the imagination. Or a phyfical fubftance, or body, in oppofition to fpirit, or metaphyfical fubftance, &c.

PHYSICAL or fenfible horizon. See HORIZON.

PHYSICAL *agent, caufe, certitude, concrete, continuity, evidence, fate, good, liberty, neceffity, part, perfection, poffible, predetermination, premotion, qualities,* and *quantity.* See the feveral fubftantives.

PHYSICAL *Education*, is that branch of education which refpects the care and culture of the bodily powers, confidered in reference to their fubferviency to the mental powers, and the influence of the ftate of them upon the mind. As we have already obferved in EDUCATION, the organs of fenfation muft have vigour and fenfibility, in order to bring the fyftem of thought and feeling into its due ftate of perfection, both as to comprehenfivenefs and vigour, and as to proper direction: and much of intellectual improvement and moral culture depends upon the ftate of the mufcular and nervous fyftem in general. The education of the human being, as far as refpects thefe objects, may be termed *phyfical;* and by phyfical education, therefore, we underftand that feries of means by which the external organs of the mind, the organs of fenfation, and the mufcular and nervous fyftem, fo far as the mind is directly concerned in their operations, are to be preferved in a found and healthy ftate, and improved in activity and vigour.

When we confider the influence of the body on the mind in its greateft extent, we are fully aware that whatever affects the health and vigour of the body, may, with ftrict propriety, be regarded as an object of education; and in this point of view, the whole treatment of infancy, childhood, and youth, in refpect to health, whether its continuance or reftoration, might properly come under the head of phyfical education. But in the article above referred to, we expreffed our intention not to encroach upon the fcience of pathology; it would lead us into a field by far too extenfive for our limits, without affording any material aid in the object we have in view. The judicious mother may learn much from books on the difeafes of infancy and childhood, which will operate by way of caution and prevention; but we ftrongly recommend her not in general to undertake herfelf the management of thofe difeafes, but to obtain good medical advice. We do not doubt that the parent who has a tolerable acquaintance with the nature of the bodily conftitution, and has had the advantage of much experience and obfervation, will often be the beft phyfician for her children: but there are few who would not be benefited by the advice of others in all cafes which may permanently affect the health; and, in general, by far the fafeft and beft way is, early to call in that aid which medical fkill may fometimes effectually afford, without tampering with the conftitution by the ufe of powerful remedies, or even of common ones too frequently. Still, however, we are fatisfied that the judicious mother may derive from books much important information refpecting the medical treatment of her children, particularly in the early periods, and in the way of *prevention;* and we may be allowed, as we go along, to recommend one work which we have reafon to believe of great value, *viz.* Underwood on the Difeafes of Children. In mentioning this, we are at the fame time aware that much that is valuable may be derived from Mofs, Hamilton, &c.

While we are referring, as we frequently have done in the preceding articles on this fubject, to the mother's fhare in early education, we feel aftonifhed that the moft important objects of female education are fo much neglected. Were they generally educated with a fpecific view to their afterwards filling fome of the moft important relations of domeftic life, the next race, or, at fartheft, that which follows, would be, without example, wife and good. If fuch were the views adopted in education, it would then be a primary object to cultivate their *underftandings;* to give them folidity, accuracy, and comprehenfivenefs of judgment; and to ftore their minds with that correct and important information, which would enable them, in their turn, to train up their own offspring, or the offspring of others, in that way which would give them the greateft probability of being vigorous, healthy, and active in their bodily powers, and lay the beft foundation for intellectual and moral excellence. A woman may not be a wife or mother, but fhe can fcarcely fail, if properly prepared for thofe relations, to be led, in fome way or other, to fill fituations in life, bearing confiderable refemblance to them in their effects on the improvement and happinefs of others.

In MORAL *Education*, col. 1—3, we have referred to the intimate connection which exifts between the cultivation of the moral and intellectual powers. In fact, neither can be neglected without ferious injury to both; though the influence of moral education upon the culture of the underftanding, is decidedly the greateft and moft extenfive. Phyfical education, in like manner, bears a clofe connection with the other branches; and, indeed, it lies at the foundation of both. But it can feldom, if ever, be neceffary to make it an object *altogether* independent of the culture of the mind; and if purfued folely in reference to the animal health and ftrength, there is no doubt that the feeds of their deftruction will often be fown, by the very means which are employed to promote them. This is a truth which may, at firft fight, appear rather paradoxical; but we leave it, with full confidence, to the confideration of the judicious obferver, who will find it more particularly true with refpect to boys. We are perfectly difpofed to admit that the care of the bodily health fhould be a primary object in the early periods of education: and we are certain, that by making this, in a proper manner, a primary object, the ulterior ends of education will be beft accomplifhed: but then it fhould be purfued with a view to thofe ends; and if it be not, it will itfelf, in all probability, defeat its own purpofe. An unreftrained mind in a vigorous body cannot fail to be eventually a flave of the body. In fubfequent periods of education, mental and moral culture may, and muft be, the leading objects; but they too will, in a confiderable degree, defeat their own ends, if purfued without reference to the bodily health and vigour. We would by no means intimate that debility of body, or extreme phyfical fenfibility, is *neceffarily* attended with ill effects on the moral and intellectual fyftem. Under judicious management, they often have led to high degrees of moral worth, and have not prevented very great progrefs in mental culture; but their general tendency is, on the one hand, to produce debility of mind, and the moral qualities connected with it, cowardice, meannefs, &c.; or, on the other, that extreme infenfibility which will either fpeedily confume the powers of body and mind, or fink into felfifhnefs of the moft injurious kind, becaufe it often wears the garb of benevolence.

Whatever be the nature of the immediate organs of the percipient principle, there can be no doubt that they depend greatly upon the bodily fyftem. Whatever be the nature of the organifation upon which fenfation, retention, affociation, memory, and imagination depend, it is indifputable, that it is moft intimately connected with the material organifation which is connected with any of the operations of the mind. As far as the judgment depends on thefe fubordinate powers, this alfo muft be affected by whatever affects them. Taking the term in its wideft fenfe, the

memory

memory is neceſſary to the judgment; it ſupplies it with its materials for diſcrimination, compariſon, &c. ſo that without it there could be no exerciſe of judgment; and if there be a deficiency in the calls for this exerciſe, whatever "high capacious powers, lie folded up in man," however great the natural capabilities of the mind, they never can be properly and fully evolved. That the elementary powers forming the memory and imagination, are very greatly dependent upon the body, is a point ſo well aſcertained, that we may aſſume it as a fundamental poſition; and the cloſe connection, therefore, between the culture of the underſtanding and a ſound and vigorous phyſical ſyſtem follows at once as a neceſſary conſequence.

We conſider it as an eſtabliſhed truth in mental ſcience, that ſenſations are the rudiments of all our mental pleaſures and pains, and alſo of all our intellectual ideas, except thoſe immediately derived from conſciouſneſs. The reader of the article *Mental* PHILOSOPHY would perceive that we do not neglect the direct influence of the underſtanding in aiding, modifying, or reſtraining the operation of the aſſociative power on the relics of ſenſation: but however great this influence, the above ſtatement is no leſs true; and we think it an important truth. We have, however, already ſaid enough on this fundamental poſition in the firſt diviſion of INTELLECTUAL *Education*, and near the beginning of the ſecond in MORAL *Education* (ſee alſo MENTAL *Philoſophy*, Div. II.): and we ſhall, therefore, only add here, that the buſineſs of phyſical education, as we have defined it, is, to keep not only what are generally known by the appellation of the external organs of ſenſation, but the whole muſcular and nervous ſyſtem, in a ſound and vigorous ſtate, or to bring it into that ſtate, and this not only with a view to the health of the body, but alſo to the intellectual and moral welfare,—in other words, to the worth and happineſs of the individual.

The capacity of ſenſation may, no doubt, depend upon the peculiarities of the mind itſelf, of the percipient principle (whatever that be); but without reſorting to an opinion which probably can never be proved, we ſee enough in the diverſities of the bodily organs of ſenſation, taken in all its varieties, to account for all the known diverſities in *ſenſation*, (conſidered of courſe as diſtinct from perception); and we, therefore, do not heſitate in the belief, that this elementary principle of the mind depends upon the corporeal ſyſtem. How far this is the caſe with reſpect to aſſociation, conſidered as diſtinct from ſenſation and retention, we have no certain means of aſcertaining; but various facts lead to the belief that it is to a very great extent. The power of retention, there can be no doubt, depends greatly upon the ſtate of the corporeal ſyſtem; and, indeed, the ſtatements of different writers reſpecting the influence of the bodily ſtate on the memory, may be applied partly to the aſſociative power, and partly to the power of retention. Altogether, however, there is no room for reaſonable doubt, that the elementary powers of the mind, by which almoſt the whole of its furniture (of intellect and affection) is acquired, depend in their original operation upon the ſtate of the phyſical ſyſtem, and are modified by it through life. Indeed there are few who by the influence of external cauſes or of their own voluntary efforts, are able to cement that influence.

We are fully ſatisfied that there are decided original differences, not only in the powers of ſenſation, retention, and aſſociation, but even in the judgment; and probably the three former are, by their very nature, directly dependent upon original peculiarities of the phyſical organiſation, the varieties of which, if we may judge from external appearances, are indefinitely great. But we ſee no reaſon to doubt that the defects or exuberances of all of them, may be conſiderably, though not entirely, corrected by direct or indirect culture; and that this muſt be done, in the firſt inſtance, by means of phyſical education. If there be an exceſſive degree of phyſical ſenſibility, the object muſt be to leſſen it. In all probability, when the body is healthy, there ſeldom, if ever, is too little, as far as reſpects the mere capacity of pleaſure and pain; but in reference to the acquiſition of intellectual ideas, the organs of ſenſation often admit of great improvement in the power of receiving and conveying to the mind the rudiments of knowledge. However, the grand point is, if poſſible, to make and preſerve the body ſound and vigorous, in that ſtate in which "life is felt in every limb:" preſuming that the influence of this ſtate upon the mental and moral powers, if accompanied with a proper attention to their culture, cannot be otherwiſe than beneficial; and that the contrary muſt often be highly prejudicial: directing the attention to the ſupply or correction of the influence of the body on the mind; and in all inſtances aiming to make the degree of muſcular or nervous health poſſeſſed, as beneficial as poſſible in its effects on the internal furniture of intellect and affection.

Conſidering the mutual dependence of the body and the mind on each other, and (from the little which we have ſtated on the ſubject, and other circumſtances which will readily occur to the intelligent reader) the intimate connection which exiſts between phyſical, and intellectual, and moral education, it will ſcarcely be expected that we ſhall be able to draw a minute line of diſtinction between theſe branches of our ſubject: indeed we ſhall find it leſs practicable here than in our former articles, (in which, however, greater minuteneſs than our plan admitted, would have brought their connection more forcibly into view); nor ſhall we attempt to preſerve ſuch diſtinction. Our leading object will be,—the education of the body; but as it ſhould always be purſued with a view to its influence on the happineſs, and on the developement and culture of the intellectual and moral powers, we ſhall take it without any very nice diſcrimination, which in our apprehenſion would be wholly uſeleſs and impracticable. In ſeveral inſtances we ſhall be led to ſtate conſiderations moſt cloſely affecting moral education, in conſequence of their intimate connection with our immediate ſubject; but we doubt not that, in general, this will be ſeen to be predominant in almoſt every portion of this article.

The great point clearly is, to preſerve, or to produce, that health and vigour of the bodily ſyſtem in general, and that ſoundneſs and ſuſceptibility of the organs of ſenſation, which powerfully contribute to intellectual and moral improvement, as well as to the happineſs and uſefulneſs of the individual.

We ſhall not find it neceſſary to enter very minutely into detail on the means by which theſe objects are to be effected. The education of the body, where there is no exceſs of refinement, or perverſion of falſe philoſophy,—where, in ſhort, it is left to the guidance of good ſenſe under the influence, not of parental anxiety but of parental care,—can ſeldom fail, in ordinary caſes, if the baſis of a good conſtitution previouſly exiſt, to go on ſucceſsfully: and in extraordinary caſes, it requires the aid of what we cannot attempt to ſupply,—medical ſkill. Much information, too, may be derived from books which are acceſſible to moſt parents; and as we are more deſirous of making our pages the vehicle of uſeful truth, than of ſtriking novelties, we ſhall freely avail ourſelves of that information, where it appears to us juſt and important. In this object we have found a work, entitled "The Parent's Friend," of conſiderable ſervice; and as we were not acquainted

quainted with it when drawing up our former articles, we wish now to introduce it to the notice of our readers. It consists of "extracts from the principal works on education, from the time of Montaigne to the present day (1802), methodized and arranged, with observations and notes by the editor." As the opinions adduced are sometimes in direct opposition to one another, and still more frequently in their connections and consequences, it may perplex those who are not accustomed to think and judge for themselves, but to those who are, it will afford many useful hints, and much valuable information; and by observing the variety of opinions on subjects, which, at first sight, may appear of obvious and easy decision, it will lead to more extensive examination, and leave the mind more free from the undue influence of authority, in a case in which the judgment alone should have the predominancy. We shall be indebted also to that singular work, "The Light of Nature pursued," and though we know not how to give an indiscriminate recommendation of Dr. Beddoes's Hygeia, yet we cannot doubt that the judicious parent may derive from it, as we have done, many valuable observations, which may be of singular use in the work of physical education. In one division, Dr. Currie's Medical Reports will supply us with some very important observations. When we have made such use of any of these writers, as appears to require acknowledgement, we will specifically refer to them.—We will begin with the following quotation from Search, which will give the reader a specimen of the author's peculiar style (see *Mental* PHILOSOPHY, near the end of Div. I.), and at the same time convey some very useful principles in the conduct of this and other departments of education.

"It is very material whether this principle (parental affection) be left to operate at random, solely by its own impulses, or guided by judgment and discretion. If due consideration be had," children "will not be regarded merely as play-things for the parents to divert themselves with, or shew about among their friends and visitors, to remark how tall, how lusty, and how lively they are; but as an important charge committed to our hands, as our nearest neighbours, whose fortune in this world and the next depends upon our management; which, therefore, deserves to be esteemed a serious affair, and be made the object of our constant attention. For *the constancy of the application is of more consequence than the vehemence of it;* as a little negligence or indiscretion will overthrow the good effects of many cares. People are apt to be prodigiously anxious for their children by starts, just when it comes strongly into their heads, and then think no more of them for long intervals afterwards. In their serious moods they collect treatises of education, in hopes to find a secret there for becoming excellent managers by the bare perusal; but these aids at most can only direct them, in some particulars, how to apply their industry, but can never infuse it: they must draw this principle from their own fund, and have gotten an habitual diligence, before they become qualified to reap any benefit from the observations suggested to them. *It is not a set of rules, how complete soever, but a steady vigilance and readiness to seize every opportunity of practising them, that must do the work.* Where there is the latter, it will go a great way towards supplying deficiencies in the former: for we see people, with very little knowledge or judgment, succeed well enough for common use, by an assiduous application of such judgment as they have; and there are more errors committed in the world through negligence than ignorance."

We fully agree with this singular writer, that the physical education of a child may be considered as commencing even before its birth. How his moral welfare and happiness are affected by his being the offspring of an illicit connection, the reader may see well delineated in the Light of Nature pursued, if his observation do not furnish him with abundant proof. This we shall not extract or abridge, but will quote another passage, bearing more directly upon our immediate object. After having made some excellent observations on the duty of exercising prudence in forming the conjugal relation, and of giving some little consideration "what other parent we give our children, upon whom their future health of body and mind is to depend jointly with ourselves," he proceeds: "But happiness is made up of many ingredients, requiring forethought to provide for them; and if any principal ingredient be wanting, it will render all the rest of no avail: therefore, it is a cruelty, or at best an unpardonable negligence, when people entail diseases, distemperature of brain, weakness, or poverty, upon their offspring, by unsuitable matches, or provide them with a parent who knows nothing but trifling dissipation and amusement, incapable of steadiness, or consideration, or of helping them either by instruction or example. This is sacrificing their children to their own fond fancy, or the glare of riches and splendour, whichever of the two idols happens to possess their imagination." He does not expect that every thing could be exactly according with our wishes, nor pretend to determine to what point precisely the interest of the parties is to give way to that of their probable offspring; but maintains that this ought not to be overlooked, as it so frequently is, especially by very young persons. "And if such weight has been given," he continues, "in making the connection, I presume it will not cease to operate afterwards during the time of gestation; but the mother will abstain from such intemperances, diversions, and hazards, as might prove hurtful to the burden she bears, preserving such a steadiness and sobriety of temper, as may secure her against frights and longings; and the father will strive to ward off whatever might excite any turbulent passions, or urge to any improper exercises, which would disturb the vegetation of the growing plant, or vitiate its juices." During the period of gestation, the mother ought, in the most careful manner, to avoid every thing which may produce bodily constraint, such particularly as tight and cumbersome dresses; all the productions of the tyrant fashion, which tend to impede the free developement of the fœtus, as well as to render delivery more difficult. She should, for a similar reason, avoid every kind of agitating exercise, such as riding in carriages with rapidity on uneven roads, dancing, lifting or carrying heavy loads; in short, all fatiguing employments whatever.

Among the predisposing causes operating powerfully to check the processes of physical education, may be mentioned early marriages; where the mother, especially, is not arrived at that period of bodily vigour, which may give her offspring a common chance for health, nor her mind at that period of maturity which may enable her, with advantage, to discharge the duties of a wife and a mother. "Be silent for two years," is somewhere mentioned as the judicious advice of a young lady to her lover; and it would often be indeed for the happiness of the parties, as well as for the welfare of their families, if this were given, with the specific view above referred to. If affection would not stand such a trial, neither in all probability would it the trials of life.

In the remaining part of this article we shall endeavour to bring, what appears to us of chief consequence in physical education, under the following divisions:

I. *Air, Temperature*, &c.

II. *Cleanliness, Bathing*.

III. *Clothing*.

III. *Clothing.*
IV. *Beds, Sleep.*
V. *Bodily Shape.*
VI. *Diet,* &c. *Temperance.*
VII. *Muſcular Exerciſe.*
VIII. *Exerciſe of the Senſes.*
IX. *Senſibility.*
X. *Purity.*

I. *Air, Temperature, &c.*—Almoſt every one now knows, that the atmoſpheric air conſiſts principally of two parts, one of which, oxygen, is eſſential to the ſupport of life; that if this were in too great abundance, life would be ſpent too faſt; but, on the other hand, that when there is not a ſufficient quantity, (when, for inſtance, it has been conſumed by flame, or by reſpiration,) the animal ſyſtem cannot derive, from the portion of the atmoſphere which is inhaled, that ſupply which is requiſite to preſerve it in a healthy ſtate. In cloſe rooms, where there is a fire, and perhaps ſeveral candles, and many perſons at the ſame time conſuming the oxygen of the atmoſphere, there cannot be a ſufficient quantity for the proper ſupply of each. If the external air is introduced in any conſiderable quantity into ſuch rooms, unleſs due means are taken to prevent its proceeding in a current, the effect is uſually highly injurious, by the rapid ſubtraction of heat from the perſons who are within the current. In rooms which not only are not properly ventilated, but are alſo expoſed to noxious vapours of any kind, it is impoſſible that health ſhould be preſerved or regained. One kind of air, (carbonic acid gas, or fixed air,) which is produced in great quantity by the burning of charcoal, is directly deſtructive; and if ever charcoal or coak are employed in rooms where there are children, though it would be better to avoid it in every caſe, it ſhould not be without the utmoſt precaution, as the carbonic acid produced, if there be not a free circulation of air, will be in the higheſt degreee deleterious, and probably fatal. Carbonic acid is produced by the burning of candles, and by reſpiration; ſo that by this means not only that part of the air is diminiſhed, which is neceſſary for the ſupport of life, but alſo another ſubſtance is added, which renders it more and more unfit for its object. Theſe things are perhaps too little attended to, even by the well informed; by the ignorant they are altogether neglected. About nine or ten years ago, it was perceived that a lime-kiln, near one of the public medical inſtitutions in Liverpool, (the infirmary, we believe,) was a cauſe of great inconvenience to the patients, whenever the wind brought the air from it towards the wards. As lime is employed, with ſo much advantage, for the promotion of health and cleanlineſs, it was thought a mere philoſophical whim to ſuppoſe that the lime-kiln could be injurious. It was, however, proſecuted as a nuiſance; and at the Lancaſter aſſizes, the jury were convinced that it was ſo, by the intelligible, though philoſophical, repreſentations of Dr. Currie,—a man who united in a rare degree the talents for profound reſearch, accurate inveſtigation, and forcible, yet perſpicuous, and even elegant expreſſion; and whoſe name will long continue to ſtand high in the annals of philanthropy and medical philoſophy. The well-known fact is, that when the lime-ſtone is being burnt, carbonic acid gas is expelled from it in great quantities, ſo as to diminiſh its weight nearly half; and it was this air which proved ſo unpleaſant and injurious to the patients: on the other hand, the ſtrong tendency of quicklime to abſorb carbonic acid from the atmoſphere, is one principal cauſe of its ſalubrious effects. One more circumſtance we muſt mention in this connection, that carbonic acid gas, being conſiderably heavier than atmoſpheric air, will, where it exiſts in any large quantity, ſink to the bottom of the room; and on this account, the beds of children ſhould not be placed on the floor. On the other hand, as heated air and (as it appears) noxious effluvia are lighter than pure air at a lower temperature, the moſt wholeſome air will be found ſomewhat below the middle between the floor and the ceiling. It is from the effect of heat upon the gravity of the air, that a fire, with a moderately open chimney, is productive of very valuable effect in producing a conſiderable circulation of the air, and carrying off that which has been already deprived of its oxygen. There can be no doubt, that a room warmed with a cloſe ſtove, other things being the ſame, cannot be ſo healthy as one with an open chimney; and it is, therefore, probable that the recently introduced regiſter-grates, where the opening is but juſt ſufficient to receive the ſmoke, will have no beneficial effect upon the health, though they may be more economical of fuel. In rooms for children, the due medium ſhould be obſerved; but the wider the chimney the better, ſo long as it does not cauſe currents of cold air in the room.

This ſhould be carefully avoided, eſpecially in the room deſigned for the habitation of an infant. Violent inflammatory complaints are often produced by inattention to this circumſtance. Among the poor a breach in the window, or a fiſſure in the wall, oppoſite the ſpot where the infant is uſually held, have been attended with ſerious conſequences of this nature; and the ſame thing has occurred in opulent families, by the ſhrinking of the ſaſh frame or a board in the floor, or of ſome other wood work, which has admitted a ſtrong but unperceived current. "The fire-place ſhould be contrived that even in cold weather a ſteady temperature of about 60° may be kept for the firſt four or five weeks after birth. The air of the nurſery ſhould not be ſuffered to be below 50°." The heat ſhould be regulated by a thermometer. If the uſe of ſuch an inſtrument be not thought ſuperfluous in a hot-houſe, for the purpoſe of ſecuring the well-being of an exotic plant, it ſhould not be thought unneceſſary for the regulation of the temperature in which a little being is to be ſituated; equally tender with an exotic plant, arrived from as warm a climate. Few fathers, when once convinced of the propriety of a *ſteady mild* temperature, will heſitate to dedicate their moſt ſuitable apartment to the health of their offspring. Small nurſeries cauſe many complaints, and many bad conſtitutions. If the door is kept partly open for the purpoſe of admitting air, the current is great and injurious; and a fire ſomewhat too briſk, produces a degree of heat which will aggravate ſome diſeaſes, and greatly enervate a habit conſtantly immerſed in it. (Beddoes, Eſſ. v.) Here, and in ſome other inſtances, in abridging from Dr. Beddoes, we have availed ourſelves of the abſtract in Dr. Stock's valuable Life of Beddoes.

The motion given to infants ſhould at firſt be gentle, on account of the extreme ſuſceptibility of the membrane which lines their noſtrils and air-paſſages, (the mucous membrane.) It produces a conſiderable irritation which keeps up the ſuſceptibility of the membrane; and this ſometimes lays the foundation of aſthma at a very early age, and more frequently a propenſity to colds. The uſe of the cool bath at firſt, and afterwards of a cold one, is the ſafeſt and moſt effectual method of diminiſhing this extreme ſuſceptibility, and of habituating the whole body to variations of temperature. For a new-born infant Dr. Beddoes prefers immerſing up to the neck in water at 88°. "In a week the temperature may be reduced to 75°, and progreſſively to 60°, at which point we may ſtop for a twelvemonth." The ſevere diſcipline of waſhing in ſpring

water.

water, of the natural temperature, ſhould only be gradually reſorted to, and never until the ſtrength of the infant is ſufficient to reſiſt its chilling influence. When the ſkin is in a hot and dry ſtate, the body may then be bathed with advantage in tepid water; or the child ſhould be taken into a room without a fire, and gently carried about till it returns to its natural temperature. This, when there is no feveriſh diſeaſe, will ſoon happen. The ſame plan ſhould be purſued when it is hot, reſtleſs, or uneaſy at night, for which purpoſe it ſhould be taken out of bed. On the other hand, when the extremities are cold and clammy, gentle friction before a moderate fire with the hand, or with a ſoft fleſh bruſh, is recommended, with the internal uſe of ſmall quantities of thin animal broth, a little above blood heat. To this, immerſion in a warm bath at 96° may be added, and repeated, if occaſion require, four or five times in the day. Beddoes.

In cold ſeaſons, the removal of children into the open air ſhould not be precipitated. It is better to be content with habituating them to thoſe variations of temperature which different rooms in the ſame houſe will at firſt ſupply. They ſhould not at firſt be carried into the cooler room, except when they are rather warm, and then only for a ſhort time. Where likely to be met by ſtreams of air, the whole head ſhould be covered, allowing ſufficient breathing room. They ſhould be rendered hardy, by expoſure to a cold calm atmoſphere, for a ſhort time at firſt, and at no time till they are chilled. They ſhould never encounter rude blaſts till they can move briſkly enough to produce warmth from within, and then only at intervals ſucceſſively prolonged. "The parents who feel a juſt confidence in the robuſtneſs of their offspring, will do no injury by proceeding with a meaſured pace. We have acceſs to no river Styx, in which one immerſion ſhall render us invulnerable to the elements." The ſuperiority of thoſe who have been accuſtomed to face the ſevereſt variations of temperature, to the "inactive fire-ſide tenderling" in vigour and health, would naturally enough lead to the ſuppoſition,—that to endue a young perſon with theſe deſirable qualities, nothing more was neceſſary than to expoſe him ſufficiently to the cold. From this prejudice many conſtitutions have ſuſtained irreparable injury. The true principle is, *gradually to inure the habit to cold;* and a good conſtitution may thus be enabled to bear ſevere and long continued cold without detriment: but *as ſoon as a chill comes on, the proceſs ſhould be ſuſpended;* for in the ſtrongeſt conſtitution, "long continued and repeated chills will, in the firſt inſtance, enfeeble, and, in the ſecond, bring on a ſuſceptibility to the operation of the powers that ſuperinduce violent diſeaſes." Beddoes.

One great ſource of injury from diminiſhed temperature, is to be found in the cuſtom of bathing or ſwimming, when too long protracted: but ſome remarks on this head will come more properly under the next diviſion.

A grand cauſe preventing that invaluable ſtate of the bodily ſyſtem, which we will term hardineſs, is the dependance placed upon external warmth for producing a comfortable ſtate of ſenſation. It is a fact inconteſtibly proved that the continued application of external warmth *renders the living ſyſtem leſs capable of being called into ſtrong, healthy, or pleaſurable action.* Every muſcle ſteeped in a heated medium, loſes of its contractility: every nerve grows languid; and when excited, acquires a diſpoſition to throw the moving fibres with which it is connected into convulſive movements. Inſtead of accuſtoming our children therefore to heated apartments, from which every breath of air is excluded, we ſhould lead them to ſeek for warmth by exerciſe, or provide them with it by that kind and degree of clothing which will confine the animal heat, and thus in reality encreaſe it. Beddoes.

Till hardineſs has been acquired, and perhaps even after, ſudden variations of temperature can ſcarcely fail to be attended with injurious effects upon the bodily ſyſtem. This is the chief cauſe of colds, or catarrh. The inflammatory ſpecies of catarrh are not ſimply owing to cold, but ariſe from the concurrent or ſucceſſive action of cold and heat, or of ſtimuli equivalent to heat. If the cold to which the ſyſtem has been expoſed was conſiderable, heated apartments and warm ſpirituous liquors concur in carrying inflammation to its juſt height. It is well known that frozen limbs will inflame ſo as to mortify, if they be not carefully kept from the contact of mediums which are conſiderably above the freezing point; and the remedy is to rub them with ſnow. When the mucous membrane has been chilled by froſty air, it is reaſonable that a ſimilar method ſhould be adopted,—gentle exerciſe in an atmoſphere not much exceeding the temperature by which it has been chilled, and the avoiding for the day all kinds of heating liquids. Beddoes.

The beneficial effects ariſing from the expoſure of the bodily ſyſtem to the external air, ſeparate from thoſe ariſing from exerciſe, are, in the firſt place, ſupplying it with air containing a due proportion of oxygen, which can ſeldom be obtained in rooms conſtantly inhabited by ſeveral perſons unleſs thoroughly and frequently ventilated; and next, taking away a portion of the ſuperfluous heat from the body. Hence, though exerciſe within doors is much better than no exerciſe at all, yet the bracing invigorating effects of the external air can ſeldom be thus obtained, and indeed never, except in a cool room kept well ventilated. When children, therefore, have ſufficiently gone through the hardening proceſs to bear it, they cannot be too much in the external air, as long as they are free from chillineſs. The dry cold eaſterly and north-eaſterly winds, and the dampneſs ſo frequent in our climate, on the one hand, and the exceſſive heats of ſummer on the other, ſhould certainly excite the parent's caution; but when the air has ſufficient coolneſs in ſummer, and is ſufficiently dry in the other parts of the year, almoſt continual expoſure to it, with the above precaution, cannot fail to be beneficial to the conſtitution properly prepared for it. As the requiſition of phyſical health ſhould be the chief object of the firſt period of education, the parent ſhould embrace every opportunity of giving his children the full benefit of this means of health.

Regularity in mental employments is of very great importance, and the habit ſhould be early formed, but the requiſite arrangements ſhould be ſo contrived, as to interfere as little as poſſible with this moſt eſſential point.

It is a well-known and important principle of chemical philoſophy, that ſolids when changing into fluids, and fluids when changing into vapour, abſorb heat. And where this is not ſupplied with ſufficient rapidity by the immediate cauſe of the fluidity or evaporation, the ſubſtance undergoing the change abſtracts heat from all the ſurrounding ſubſtances, in other words produces a greater degree of cold. It is on this account that, though the atmoſphere may be warm during a thaw, the body, when near the melting ſubſtance, generally feels chill; and that the ſame effect is experienced in damp weather, ſince the heat of the body produces a degree of evaporation from the damp on its ſurface; and the ſame effect is produced in a greater degree, and often without being immediately experienced, when wet clothes (the ſhoes and ſtockings for inſtance) are rapidly dried whilſt they are worn, and at the ſame time the body not ſupplied

plied with natural heat by exercife of any kind. Indeed there are few conftitutions, unlefs they have gone through the proceffes of hardening to an uncommon degree, which can avoid being injured by this common practice. The intenfe degree of cold produced by evaporation, may be perceived by pumping on the hand, fo as to have only an occafional ftream of water upon it in different parts: if the hand were kept ftill in water at the fame temperature, much lefs cold would be experienced. In like manner, if the lower extremities be placed in warm water, and the water be gently agitated, fo as to expofe part of the wet furface of the leg to evaporation, this part will be found very cold, while the reft is very warm. Thofe who are much accuftomed to obferve their fenfations, may perceive that even when the water is ftill, if there be fufficient warmth to produce evaporation, the part of the leg immediately above that which is immerfed, feels colder than the reft, nearly as though there were a ring of metal round it. Perhaps, however, the effect may be moft completely perceived, by firft ftanding a little before a quick fire, and then fufpending clofe before one a piece of damp flannel; if fufficiently near, and the heat fufficiently ftrong to produce a rapid evaporation, the cold produced (in other words the lofs of heat) will be very fenfibly felt, and might be made evident by the employment of a thermometer.

By attention to this principle, parents will take care, if their childrens' clothes are wet, that they either keep in fome degree of exercife till they are dry, or have them removed; that their fkin is well dried after wafhing or bathing; that their linen is properly aired (not warmed, except for weakly children) before it is put on; and that no clothes fhould be put to dry in the room in which they live. Inattention to this laft circumftance, in the nurfery particularly, is a common caufe of chill and colds among infants. When we confider, however, how little injury is experienced by alternations of heat and cold in the hands, or by their expofure to damp, how little, too, where the feet are continually expofed to them without the protection of fhoes and ftockings, and how frequent the circumftances in real life where fome confiderable expofure muft be experienced; it is clear that caution fhould not be carried too far; the only point is *that the hardening fyftem be introduced by degrees*, and that thofe degrees be determined by the previous ftate of the fyftem, *i. e.* its capacity to endure them. To attempt to carry them on with a weakly child, as rapidly as with a healthy one, would be foolhardinefs.

We referred in a preceding paragraph to the injurious influence of the eafterly and north-eafterly winds in fpring. Thefe are not only cold, but extremely dry; and by their drynefs alone they muft act as powerful refrigerants on moift furfaces. Their effect in producing this diminution of heat is proved by the following obfervations of the late accurate and ingenious Dr. James Hutton of Edinburgh. "I ufed to amufe myfelf in walking in the fields, by obferving the temperature of the air with the thermometer, and trying its drynefs by the evaporation of water. The method I purfued was this: I had a thermometer, included within a glafs tube, hermetically fealed; this I held, in a proper fituation, until it acquired the temperature of the atmofphere; and then I dipped it into a little water, alfo cooled to the fame temperature. I then expofed my thermometer, with its glafs cafe thus wetted, to the evaporation of the atmofphere, by holding the ball of the thermometer, or end of the tube, in which the ball was inclofed, towards the current of the air, and I examined how much the evaporation from that glafs tube cooled the ball of the thermometer which was included. During the fummer feafon, in the dryeft weather that I could find, I never funk the thermometer in that manner, to the beft of my remembrance, above two, three, or four degrees. But in a cold eaft wind in the fpring, I once funk it between nine and ten degrees. It was, I believe, about the month of March or April; the fky was cloudy above, and no funfhine, and the wind was cold to the feeling, fteady blowing, but not ftrong." Hence we perceive, that the fuperior drynefs of the air in March makes moifture evaporate fafter than the fuperior heat of the fummer air: and this is independently of all funfhine. It is evident the furfaces along which the dry cold air paffes in breathing, muft be affected in the fame manner as the furface of the wetted glafs tube; and thefe furfaces thus cooled, will be ready to be thrown into intenfe action by the rays of a powerful fun in a fheltered fpot, or befide a brifk fire at home. Beddoes.

If circumftances require expofure to the external air in fuch circumftances, before the general fyftem is properly hardened, a fimple expedient which Dr. Beddoes recommends to adults, where there is a difpofition to catarrh, may be employed with great advantage; *viz.* to place a fufficient number of folds of gauze or muflin over the mouth and nofe; it will not only warm the air before it enters the refpiratory paffages, but likewife give it moifture when the air is dry as well as cold. There are probably few travellers who have not experienced the beneficial effects produced by faftening their comforters over the lower half of the face.

II. *Cleanlinefs, Bathing.*—We perfuade ourfelves that it cannot be requifite, in the prefent day, to urge upon parents the neceffity of the ftricteft attention to the cleanlinefs of their children. The old maxim, "cleanlinefs is next to godlinefs," has a degree of truth, in a moral as well as phyfical point of view, which it may require fome experience in life to perceive, but which obfervation will completely prove to all who will not abfolutely clofe their eyes to what paffes without them. A want of cleanlinefs is almoft univerfally united with carelefsnefs and indolence. It renders the body fufceptible of infection, while the contrary practice affords the greateft fecurity againft virulent difeafes. There can be no reafonable doubt that cleanlinefs is one grand caufe why the rich efcape fo much more than the poor from infectious fevers; and that their prevalence and virulence among the poor, are, in a great meafure, to be attributed to the want of it in their perfons and in their dwellings, &c. Perfonal cleanlinefs, and cleanlinefs in the apartments in which children live, fhould be moft ftrictly enforced; and fuch a regular fyftem fhould be early adopted, as may fecure this moft defirable end. No day fhould pafs, except when the bodily health is materially interrupted, without a complete wafhing, not only of the extremities, but of every part of the body; and if this cannot fafely be done with cold water, it is extremely feldom that it may not with cool or tepid water. Children fhould be early accuftomed to wafh themfelves, but it fhould be under careful infpection till they have completely formed the habit of doing it thoroughly; and when this is done, it will be as unpleafant to them to omit it, as to fome it appears to be to make themfelves clean. When paft the early periods of childhood, it will often be impracticable to carry on the fyftem of univerfal wafhing; but it fhould be made as general as poffible, and for the purpofe of cleanlinefs, as well as of invigoration, the bath fhould be employed as frequently as domeftic circumftances, or the ftate of the conftitution will allow: with refpect to the former, by fuitable management they might generally be made to bend to the latter.

Bathing certainly ought to be regarded as having a powerful efficacy on the fyftem; and if its effects appear to be be injurious, before it is much persevered in, medical advice should be obtained. The advocates for *tepid* bathing seem to have great reason to recommend it as a valuable remedy, or even as a preservative in cases where the constitution is weakly, and has consumptive tendencies; but the facts which they adduce, rather prove it, we apprehend, to have a stimulating and relaxing influence, than an invigorating efficacy; and the warm bath at least should seldom be employed, except by medical direction, in reference to the particular case. As our present object is not the recovery of health, but the invigoration of a system which is at least tolerably free from direct tendencies to disease, we will leave the subject of warm bathing to the physician. No doubt cold also requires caution. Where the constitution has any direct phthisical tendencies, or is peculiarly weakly, it would be rash to expose a child to it; but we cannot doubt that in other cases, cold, or at least cool, bathing, employed with precaution, and in that way which experience may shew to have the most beneficial effects upon the system, has a highly important effect in giving strength and activity, or in keeping up the tone and vigour of those who are already robust.

If the *cold* bath is employed, the system should be *gradually* brought to the capacity of bearing it. There are exceptions to the necessity of this rule: and amongst the ancient Germans, (as at present among the Russians,) immersion in cold water was employed in the earliest periods of infancy: those who survived the experiment were without doubt rendered more hardy by it; but in all probability, numbers sunk under it. It is an experiment which no parent ought to try, without a well-grounded confidence in the strength of his child's constitution; and as the same effects may be *safely* produced in a more gradual way, it seems to us a risk which few circumstances can justify.

We strongly recommend to the intelligent parent, the perusal of Dr. Currie's Medical Reports "on the effects of water, cold and warm, as a remedy in fever, and other diseases, whether applied to the surface of the body, or used internally." It is a work which can scarcely fail to afford a warm interest to any one accustomed to accurate observations and scientific researches. The 15th chapter, containing "an account of the remarkable effects of a shipwreck on the mariners, with experiments and observations on the influence of immersion in fresh and salt water, hot and cold, on the powers of the living body," must be regarded as a fine specimen of philosophical investigation; and a young person, properly prepared for it by previous information, would find it a highly useful *study*. We recommend this work to the parent, because he will find in it some highly important principles respecting the effect of water upon the animal system, which may be applied with great advantage in a state of health, and which, in those emergencies which sometimes occur in sickness, may be the means of preserving life in his family, or among his neighbours. To enable a person to employ these principles in cases of illness, he must study some parts of the work itself (see BATHING); but we shall select those which will prove of immediate importance in physical education. It is to be observed that Dr. Currie applies the term *tepid* to water heated to that degree which is warm, but not hot to the sensations, which, in the way of *affusion*, is from 87° to 97°. When the body is *immersed*, it may be applied to water some degrees higher. (Vol. i. p. 69.) "By the term *cool*," he afterwards says, p. 75, "I indicate from 87° to 75°;" and as this obviously refers to affusion, we may suppose that *cool* in *immersion* extends from about 82° to about 70°: but as far as the sensations are concerned, there is no doubt that great variation will be experienced from the comparative temperature of the air, and its bracing effects on the system. The writer of this article recollects finding freezing water produce a sensation of comparative warmth, while immersed for a short time in it; and in the employment of a shower bath, in the winter months, has generally *felt* the water to be warmer in a cold frosty morning, than in a mild damp atmosphere, when the water itself must have been of considerable higher temperature. 1. The principle which Dr. Currie lays down respecting the use of the aspersion or affusion of cold water, in fever, will afford a good direction respecting the use of cool or cold bathing generally. It may be safely used, "*when there is no sense of chilliness present*, when the heat of the surface is steadily above what is natural, and *when there is no* general or profuse sensible perspiration." (P. 17.) For our purpose, the second clause may be changed into—"*when the heat of the surface is not lower than what is natural*," and the whole will then form an excellent aphorism. 2. The following statement appears to us, from repeated experience and observation, to convey the precise effects of cold bathing, where judiciously conducted. After having expressed his opinion (p. 70.), that in some cases the heat is lowered more speedily by the affusion of tepid than of cold water, Dr. Currie adds: "the evaporation from the surface is more copious from the tepid affusion; and on this the cooling of the body very much depends. But this is not all. The tepid affusion is little, if at all, stimulating, and does not, like the *cold affusion*, *rouse the system to those actions by which heat is evolved, and the effects of external cold are resisted*." It is on this principle that Dr. Currie considers the tepid affusions as a valuable remedy, in a great part of the feverish affections of children. 3. Speaking of the effects of spunging or wetting the body with cold or warm vinegar or water (p. 73.), he says: "According to my experience, it is not only less effectual, but in many cases less safe; for *the system will often bear a sudden, a general, and a stimulating application of cold, when it shrinks from its slow and successive application*." On this principle, which, we are satisfied from various considerations, is fully applicable to cool or cold bathing, we hesitate not to recommend immediate immersion, either by plunging in entirely, which, with care, can seldom be injurious, or getting in deep at once, and speedily covering the head with water; or, if the shower bath is employed, that the holes should be so large as to allow the water to come through rapidly. Experience will shew that this last precaution is of considerable importance. If the holes are small, the sensation is itself unpleasant and continued, and the partial evaporation often produces chilliness. When this is the case, bathing never can be beneficial. 4. The cool affusion "operates as a gentle stimulant, and may be used as a milder form of the cold affusion. Like the cold affusion, *its application should be sudden and momentary*, *when the object is to increase the tone of the system*, or to dissolve a morbid catenation. When it is employed to moderate inordinate heat, it may be used more slowly, provided it does not interrupt the catenation on which respiration depends." (P. 76.) We are not forgetful of the difference between the diseased and the healthy state of the body; but we see every reason to believe that this, and similar cautions, are applicable to both. 5. "The pernicious effects of cold water applied internally and externally, during profuse perspiration, depend upon the same causes, *viz.* that perspiration itself is a cooling process, under which, when profuse, the heat of the body, whatever its natural state may be, is sinking; that under such circumstances, we find, as a matter of fact, that it parts with its remaining heat more easily; and on the sudden application of cold, that this heat sinks to a degree which

which difturbs, and fometimes wholly interrupts the actions on which life immediately depends." The 12th chapter is one which cannot fail to be very interefting to the general reader. It is entitled "Of the difeafe that arifes from drinking cold liquids, or ufing the cold bath after fevere exercife;" and contains many remarks, which the claffical ftudent will find of advantage to him in his refearches. Into thefe we muft not enter, but confine ourfelves to our prefent object; including, however, fome pofitions more immediately refpecting the ufe of cold water internally. The general fact is, 6. That the fatal effects proceeding from drinking cold water, in cafes where the fyftem has been extremely heated by bodily exertion, have occurred in circumftances, "where the fyftem, after having been much heated and enfeebled by fevere exertion, is lofing its preternatural heat from profufe fweating, and in general alfo from the ceffation of the exertions, by which this heat was originally produced. Here two powerful caufes combine to cool the body; and if, under their operation, a fudden application of cold is made either to the ftomach or the furface, the living power will, we know, refift it faintly, and the fatal confequences be accounted for." Dr. Currie then gives a number of cafes, which fhould be read by the parent to his children, as foon as they are capable of fully underftanding them, and afterwards brought back to their memory, as circumftances direct; and the fame by the tutor to his pupils. And the parent and preceptor fhould be acquainted with one fimple remedy, which, in cafes where the injury has not been too great, may prove effectual in reftoring vital heat, namely, "the application of a bladder filled with water, heated to 110° or 115°, to the pit of the ftomach." 7. "There is no fituation in which the application of cold to the body, whether to the furface or the ftomach, is fo fafe, or in general fo falutary, as when the heat of the body, from whatever caufe, is preternaturally great; provided that the body is not already in a ftate in which it is rapidly parting with this heat, and no difeafe has taken place in the general fenfibility, or in the ftructure of any of the parts; and that when the body is preternaturally heated, the degree to which cold water may be drunk may be always decided by the fteadinefs of the fenfation of heat, and the tenacity with which the preternatural heat is actually retained. With this obfervation, however, muft be connected another, "that the heat preternaturally accumulated by exercife is held with lefs tenacity than even the heat in intermittents. It is diffipated by the perfpiration that exercife occafions; and is fpeedily loft, when to profufe perfpiration is added a ftate of reft. It is then that a large draught of cold liquid is efpecially dangerous. But while the preternatural heat is fuftained by continued exertion, cold liquids may be taken *in moderate quantities*, without producing any injurious effects. They may even, I apprehend, be drunk copioufly, without producing fuddenly the fatal effects already defcribed: but in copious draughts, they are found oppreffive to the ftomach during exercife, and excite languor, naufea, and fometimes vomiting." Dr. Currie afterwards explains the difference between the influence of water taken into the ftomach and ufed externally; which arifes, he obferves, partly from the weight and bulk of the fluid, particularly oppreffive under the conftant action and agitation of the voluntary mufcles, and partly from the evaporation from the furface being promoted by the immediate accefs of external air. To thefe muft be added another fimple confideration, that where the external application is voluntary, it may be much more readily removed, and its injury checked, than where it is taken into the ftomach; and this is of obvious importance. "With thefe exceptions," he adds, "the operation of cold liquids on the ftomach, and on the furface of the body, are analogous in the cafe of preternatural heat produced by bodily exertion, as in all other cafes of preternatural heat. As it is fafe to drink cold water, in proportion as the heat from exercife is great and fteady; fo alfo is it fafe, according to this ratio, to pour it on the furface, or to immerfe the body in the cold bath." 8. "In the earlier ftages of exercife, before profufe perfpiration has diffipated the heat, and fatigue debilitated the living power, nothing is more fafe, according to my experience, than the cold bath. This is fo true, that I have for fome years conftantly directed infirm perfons to ufe fuch a degree of exercife before immerfion, as may produce fome increafed action of the vafcular fyftem, with fome increafe of heat; and thus fecure a force of re-action under the fhock, which otherwife might not always take place. The popular opinion, that it is fafeft to go perfectly cool into the water, is founded on erroneous notions, and is fometimes productive of injurious confequences. Thus, perfons heated, and beginning to fweat, often think it neceffary to wait on the edge of the bath till they are perfectly cooled; and then plunging into the water, feel a fudden chillinefs that is alarming and dangerous. In fuch cafes, the injury is generally imputed to going into the water too warm; whereas in truth it arifes from going in too cold. But though it be perfectly fafe to go into the cold bath in the earlier ftages of exercife, nothing is more dangerous than the practice, after exercife has produced profufe fweating, and terminated in languor and fatigue: becaufe, as has already been repeated more than once, in fuch circumftances, the heat is not only finking rapidly, but the fyftem parts more eafily with the portion that remains."

From the preceding obfervations it is obvious, that the cold bath fhould only be employed where the fyftem has ftrength to ftand the fhock; and then its effects can fcarcely fail to be beneficial, in invigorating the fyftem, and preparing it to refift the influence of external cold. We recollect the cafe of a youth, of about 17, by no means of robuft habit, and very liable to colds, who never was fo little fubject to them as during the winter, in which he perfevered in the ufe of a cold fpring water bath every other day. A walk of about half a mile to the bath prepared him for it: he undreffed as quickly as poffible, plunged once into the bath, and when well rubbed and quickly dreffed, on his walk home, he had the moft pleafing fenfations of vigour and activity. As the fyftem fhould be properly prepared for the excitement of cold bathing, we deem it an important precaution, at leaft for weakly children, not to employ it fafting. After a full meal, it can feldom fail to be injurious; but no time can be better than an hour or two after an early moderate breakfaft. If this cannot be made convenient, a partial breakfaft may anfwer the purpofe. We obferve this caution of experience given alfo by other writers on the fubject. "I fee no fenfe," fays Dr. Beddoes, "in the common notion, that it is beft to bathe with an empty ftomach. I would not recommend the cool bath to a perfon full gorged; but it is defirable that the ftomach fhould be in a ftate of gentle activity, as well as the external furface of the body."

Till the fyftem has acquired confiderable vigour, the cold bath fhould be employed folely with a view to its effects. Children, if the commencement of it is managed with caution, fo as not to excite terror, will foon learn to like it, and would willingly ftay in it. In fummer, when the water has been expofed to the air, fo as to acquire its temperature, this may be allowed, but rather fparingly. When boys learn

learn to ſwim, unleſs the water be too cold, the exerciſe they take in it will conſiderably check its injurious effects; but there can be little doubt that the practice, ſo common among boys, of going very frequently into the water, (two or three times in the day, for inſtance,) and ſtaying there a long time, eſpecially if not conſtantly employed there in active exertion, has ruined many a conſtitution. Till young perſons have learnt that it is a part of duty, as well as prudence, to take care of their health, and have acquired the requiſite information to prevent injury, bathing ſhould never be practiſed except under the eye of ſome judicious friend. The morning is, on various accounts, the beſt time for this exerciſe, as well as for bathing in general; and more particularly becauſe the ſyſtem is not likely to have been exhauſted by exertion and profuſe heat, and will be able, by activity in the water, to keep off chillineſs. After the firſt approach of this, no perſon ought to ſtay an inſtant in the water.

The temperature of the water muſt be an object of conſiderable attention and caution, before robuſt health has been obtained. No one can be ignorant that water from a ſlow flowing river, from the rapid ſhaded torrent, from an expoſed ciſtern, or from the well or ſpring, differs very greatly in temperature; and upon the principle, which ſhould not be loſt ſight of, of hardening the ſyſtem by degrees, the parent will not begin with water at the loweſt temperature, or near it, but go on gradually through different ſtages of temperature, carefully obſerving the effects of each, and varying from it accordingly. No preciſe rules probably can be laid down for this purpoſe; but what has been already ſaid may ſerve for principles to guide the judicious.

The difficulty of domeſtic bathing, except for the very young, has often probably prevented the employment of it. We are fully ſatisfied that the ſhower-bath, which every one may have in ſome form or other judiciouſly employed, will not only anſwer the leading objects as well as immerſion, but in ſeveral reſpects better. The principal cautions in the uſe of it, reſpecting the temperature, &c. of the body and of the water, are the ſame as thoſe for bathing in its more common form. In addition to theſe, we recommend that the child ſtand upon woollen, at leaſt not upon the metallic lining of the drawer, or the wet boards; that the height from which the water comes be not very great, in general caſes perhaps a few inches is beſt; that it is ſo contrived that the water ſhall come freely and rapidly, when once the courſe is begun; and that the quantity be not very great. We perceive no advantage, in common caſes, for more than a complete affuſion. We are ſo fully impreſſed with the importance of this method of bathing, that we ſhall juſt give a plan for the moſt convenient kind of ſhower-bath. The height may be as great as the room will allow, for the purpoſe of filling, (ſay $6\frac{1}{2}$ or 7 feet.) The frame ſhould conſiſt of four ſtout pieces of wood, (ſay 3 inches by $1\frac{1}{2}$,) ſo connected that their outſide edges may ſtand about 32 inches from each other at the floor, and 20 inches at the top. From about 10 or 12 inches from the floor, the bottom of the bath ſhould begin to ſlope downward from each of the four ſides, ſo as to form a ſquare funnel, to convey the water into a broad, but ſhallow tub below. The funnel muſt of courſe terminate ſufficiently far from the ground, to admit of the tub being eaſily removed. About two or three inches from the top of the funnel, ſome bars of wood ſhould be placed acroſs, on which a ſmall board may be faſtened for the bather to ſtand. The ſides and door may be wood or canvas. The former is decidedly preferable; and a clever workman, in making it, will take care to have as few obſtacles as poſſible to the wet draining into the funnel, and that the joints are well made. We know of no better contrivance than the common top, a tin cylinder moving in a box, pierced with large holes at the bottom, about half an inch in diameter: this, however, need not be nearly ſo large as it is ſometimes made. If the cylinder hold three gallons, it muſt in general be abundantly ſufficient. A grown-up perſon can ſcarcely require more than two gallons, and a child of ſeven or eight not above two or three quarts. But the principal point is, that this top ſhould be ſo contrived as to riſe and fall within the caſe, for the purpoſe of adapting it to the height of the bather, and alſo for the convenience of filling it. Our experience leads us to conclude, that the uſe of ſhower bathing is much prevented by the difficulty of filling it, the want of care in its conſtruction, the injudicious uſe of it, as to quantity, temperature, &c. and the damp chillineſs of the place where it is uſually kept; and we regret it, becauſe, where the advantages of an immerſing bath cannot be obtained, the ſhower-bath can ſeldom fail to be a moſt uſeful ſubſtitute, and often is decidedly preferable.

As to the comparative effects of freſh and ſalt water at the ſame temperature, we ſee reaſon to believe that the former operates ſimply by calling into action the animal powers of evolving heat, and by invigorating the ſurface: the latter has a decidedly ſtimulating effect, by its influence on the external vaſcular ſyſtem. Sea-bathing has been often found to have a debilitating effect, where freſh water, at leaſt in the ſhower-bath, has proved very bracing. Where the conſtitution is ſtrong, there needs little attention to this difference; but among weakly children, ſea-bathing ſhould be regarded more than it is, —in the light of a medicine.

We have enlarged upon this point far beyond our intentions; but it appears to us of very great importance; and conſtitutes a very eſſential part of phyſical education. Some of the other diviſions will admit of much greater brevity.

III. *Clothing*.—In our variable climate, conſiderable attention muſt be paid to the nature and degree of clothing, till a ſufficient degree of hardineſs has been acquired to render ſuch care almoſt unneceſſary; it never can be altogether unneceſſary, as long as the preſent habits of ſocial intercourſe are preſerved, and as long as perſons are ſubject to the debilitating influence of cloſe heated rooms. But our obſervations chiefly reſpect the previous ſtate, in which the ſyſtem is going through the invigorating proceſs, and among thoſe claſſes of ſociety where conſtant exertion in the open air is not employed. Exerciſe in the open air is undoubtedly the beſt means of producing animal heat, and next to that active employment within doors: but as this cannot be conſtantly going forwards, and continued, frequent, or great chillineſs ſhould be cautiouſly avoided, the clothing ſhould be ſo contrived, particularly about the lower extremities, as to prevent the internal heat from paſſing off to the colder air. Preſerving the internal heat by non-conducting clothing, ſuch eſpecially as woollen ſubſtances, is a much better preſervative from chill, than the application of external heat. The temperature of the room in which children ſpend their time, ſhould, if poſſible, ſeldom exceed 50° or 55°. It ſhould be airy, dry, eaſily ventilated, eſpecially at the top, but free from currents of air, and in order to procure warmth in cold or damp weather, ſedentary employments ſhould be continually mixed with exerciſe in which the extremities are employed. As it really is more difficult to provide exerciſe for the feet, and they are leſs employed in the uſual occupations of education, it is deſirable that they ſhould not only be dry but well clothed; and

except

except in fummer, we can fee no reafon why warm worfted or even woollen ftockings fhould not be ufed inftead of the cotton clothing too frequently prevalent. If the feet are kept warm, the body will be ufually found to take care of itfelf. Of courfe this and every other remark muft be employed with judgment; but we are fatisfied from obfervation and experience that it is the grand point. There can be little doubt that the general prevalence of flight dreffes in winter, together with the abfurd changes which are too often practifed from warm garments in the morning to flight clothing in the evening and heated apartments, conftitute one grand caufe of the unhealthinefs of that clafs of the female fex, who, unhappily for themfelves, live in the walks of fafhion. The general principle fhould be, to accommodate the drefs fomewhat to the feafon. Hardinefs fhould be fought, rather by exercife, air, general attention to temperature, &c. than by fparing clothing. When it is acquired let experiments be tried; till then, parents will do well to give their children fuch clothing as, without being heavy, cumberfome, or heating, may prevent chillinefs, both when engaged in domeftic and even fedentary occupations, and when expofed to a cold atmofphere without. As to the employment of flannel under the linen, we think it of great fervice where there is a confiderable tendency to chillinefs and even to perfpiration, provided it does not increafe that tendency. But it fhould be as thin as poffible; it fhould be frequently changed, and accompanied with a conftant attention to the invigorating fyftems. And certainly it is not fo defirable to begin a habit fo difficult to break without judicious medical advice. Whatever additional clothing is employed for winter fhould be left off with caution, and not till the mild weather of fpring, (if fuch there be in our climate,) is fairly fet in. A real fpring day has often tempted to leave off the winter clothing, and the piercing chill of the next day has caufed ferious injury. One further caution appears neceffary; after great perfpiration, unlefs the conftitution is very ftrong, the damp clothing neareft the fkin fhould be removed, and the fkin well rubbed with dry flannel or rough linen.

From the firft period of infancy the limbs fhould be allowed full play; and no excufe can juftify the parents who, from a regard to the fhape of their children, employ tight clothes, either about the body or the extremities. Modern fafhion here, however, fo much coincides with the found dictates of phyfical education, that we need not enlarge upon it. There has fcarcely been any improvement in drefs more important than the ufe of loofe trowfers and fufpenders, by which the weight of the lower parts of the drefs is fuftained by the fhoulders, inftead of throwing it, as we recollect it to have been, upon the hips, affifted by a tight bandage round the waift. Tight fhoes and tight garters (which, if employed at all, fhould always be below the knee,) impede the circulation, and are followed by confiderable injury to the lower extremities. In fact, the rule fhould be, to have every part of the drefs not fo loofe as to be cumberfome, but perfectly eafy: and whenever children complain of uneafinefs from their clothes, they fhould at once be rectified. No trouble or expence will in fuch cafes be thrown away: there is nothing pays better in the long run than early care in the department of phyfical education. If half the pains and expence were employed in making drefs convenient and healthy, that are now given to appearance, it would anfwer every purpofe.—We need fcarcely add, that in the female drefs the fame principle fhould be obferved; and except in cafes where, from medical advice, a different plan may be thought neceffary, nothing fhould induce a mother to allow her daughters any article of clothing whatever, which does not give full and free play to the exercife of their mufcles, or of the internal functions of the fyftem. In the eye of reafon that parent has much to anfwer for, who permits her daughters to ufe any article of drefs caufing compreffion about the waift; much in refpect to the health of the individual; much, too, as it refpects the health of her children, if fhe fhould be a mother, and her capacity to bring them into the world.

Attention to neatnefs and fimplicity of drefs fhould be produced, in the firft inftance, by parental care; and afterwards enforced by parental example and inftructions. This is one of the external habits, which contribute greatly to the moral and even to the mental health.

IV. *Beds, Sleep.*—In the earlieft periods of infancy it may probably, in many cafes, be neceffary to employ warm foft beds, at leaft during the winter feafon; but the fooner they can be difpenfed with the better. There cannot be a doubt that foft beds have a very enervating effect upon the fyftem: and that fo far from contributing to the proper growth of the fpine and limbs, they have a great tendency, by yielding confiderably in parts, to produce diftortion. The mattraffes on which they lie fhould not, however, be fo hard as not to yield at all. If hair mattraffes, (which muft be the beft,) are not eafily procured, they may be filled with wool or cotton flocks; the head fhould not be much raifed; the child fhould be induced to lie fometimes on one fide, fometimes on the other, and as little as poffible we apprehend on the back. A moderate curvature of the body feems preferable to abfolute ftraightnefs.

It does not appear undefirable to protect the *head* of the bed, efpecially if there be any danger of a current of air round the room; but nothing more than this. The habit of drawing the curtains clofe round the bed is highly prejudicial in confining the impure air, and producing an injurious degree of warmth. Proper provifion fhould be made for moderate warmth, but care muft be taken not to exceed it. "When young people," fays Dr. Beddoes, "complain of unrefrefhing fleep they fhould be examined in the night, and waked without compunction if found too warm. The bed clothes fhould then be thrown off, or if the dry heat be confiderable it will be beft to walk up and down the room in a drefs which fhould be contrived for guarding the hands and feet from chill, while it fuffered the trunk of the body to be freely ventilated." This may appear a precaution of fome danger, as well as difficulty; and referring to an unhealthy ftate of the fyftem, fhould not perhaps be adopted without medical advice; but on the following there can be no difference of opinion: "Whenever a perfon of feeble habit feels heated in a morning let him rife without a moment's delay." The heat of the bed is often increafed confiderably above that falutary point which at once imparts refrefhment and vigour, and then produces fever, languor, and inactivity.

We have already ftated in Div. I. that the bed fhould be raifed from the ground, fay 18 or 20 inches. As to the quantity of fleep, it muft vary greatly with peculiarities of conftitution. During the period of growth, if the temperature be not too great, and the room too confined, it is probable that eight or nine hours cannot be too much. Children under the age of eight or nine require an hour or two more. In the fummer, however, lefs will be defirable; for the cool of the evening affords a valuable time for exercife, and the early morning air fhould not be loft. The middle of the day will then be found the beft for reft, in circumftances which will not produce too much heat.

"There is an intemperance in fleep very neceffary to be guarded againft, becaufe extremely apt to creep upon young people,

people, efpecially in this cold climate, where it gives a fmart pain to jump out of a warm bed into the winter air; therefore, this is a piece of hardinefs which cannot be inculcated too early by all the means conducive thereto, whether advice, injunction, or fhame. While under the eye of parents or mafters, they may be kept conftantly to a certain hour, which will make it the eafier for them to perfevere afterwards, when gotten from under that controul; if no diforder or accident intervene, they will need no more than one nap, which cuftom will have brought to terminate of itfelf juft at the ufual hour; and then if they turn upon the other ear to take a fecond, they fhould be taught to look upon it as an intemperance, not at all redounding to their credit. But this fecond nap is not fo bad as lying awake, than which nothing tends more to foul the blood, to fharpen the juices, to exhauft the fpirits, to unbrace the folids, to heat the blood, to ftupify the underftanding, to deftroy hardinefs, and to produce other inconveniences of very mifchievous confequence. Let them feek their amufements elfewhere, but referve the bed as a place appropriated to fleep and ficknefs; for if it were poffible to live without either of thofe fufpenfions of the enjoyments of life, nobody would ever think of making a bed a part of his furniture." To make early rifing pleafant and habitual, the firft employments of the morning fhould be pleafant in themfelves or their confequences.

The practice fhould be early begun, and afterwards adhered to as conftantly as circumftances will permit, of fleeping fingly. Separate beds are of no fmall fervice to the phyfical health; they are of effential importance to the moral health. To prevent departures from this plan, the beds of children and youth fhould be made as narrow as their comfort will allow, that they may not be ufed by two, without real inconvenience. If to this feparation can be added that of rooms, no doubt the caufe of morality muft be greatly promoted; and this fhould be done wherever practicable, unlefs parents have full confidence in the delicacy of their children.

It may be worth while adding here, that fuddenly awaking young children has often a very injurious mental and moral effect. Their firft fenfations fhould be pleafant, and we admire the principle upon which that mother proceeded, who always awoke her children with a fong. Montaigne tells us, that his father always had him awakened by the found of a mufical inftrument.

V. *Care of the Shape.*—The reft of bed is peculiarly neceffary for children and growing youth, in order to afford a due degree of relaxation to the bodily fyftem; and till the age of nine or ten, (and afterwards, if there be any marks of debility from ill health or too rapid growth,) children fhould be encouraged to lie down once or twice in the day, on the carpet or on pallets, in fuch a pofture as may afford the greateft degree of relief to the mufcles and joints. "When the leaft tendency to become awry is obferved, they fhould be advifed to lie down on a bed or fofa, for an hour, in the middle of the day for many months; which generally prevents the increafe of this deformity by taking off for a time the preffure of the head, neck, and fhoulders on the fpine of the back; and it at the fame time tends to make them grow taller. Young perfons, when nicely meafured, are found to be half an inch higher in the morning than at night; as is well known to thofe who enlift very young men for foldiers. This is owing to the cartilages between the bones of the back becoming compreffed by the weight of the head and fhoulders on them during the day. It is the fame preffure which produces curvatures and diftortions of the fpine in growing children, where the bones are fofter than ufual." Darwin on Female Education, p. 76.

Some remarks which might be applicable here will be found in Div. III., refpecting the freedom which fhould uniformly be an object in drefs; and we fhall not therefore quote fome good obfervations to that purpofe, which we obferve in Darwin, but muft add his laft fentence. "A wife fafhion of wearing no ftiff ftays, which adds fo much to the beauty of young ladies, has commenced fince the above was written; and long may it continue." We are grieved to hear that this excellent cuftom is now (1814) very much laid afide; and that our fafhionable young ladies have returned to the follies of their grandmothers, increafing the injurioufnefs of their method, by making the preffure more partial. Report fays, that even gentlemen now wear ftiff ftays. To them the injury is lefs, but not trifling. But this folly can only extend among thofe whom nothing but experience can cure of folly.

"All other methods of confining or directing the growth of young people fhould be ufed with great fkill, fuch as back-boards, or bandages; and their application fhould not be continued too long at a time; left worfe confequences fhould enfue than the deformity they are defigned to remove. Of thefe the ftocks for the feet of children, for the purpofe of making them turn their toes quite out, and the frame for preffing in their knees, as they ftand erect, at the fame time, I fufpect, when carried to excefs, to be particularly injurious, and to have caufed an irrecoverable lamenefs in the hip-joint. Thefe, therefore, fhould be ufed with proper caution, fo as to give no pain or uneafy feels, or not ufed at all." (Darwin, p. 78.) "Inftead of ftocks, (fays the editor of Parent's Friend, p. 56.) I would advife, that a ftraight line be drawn on the floor of the fchoolroom, from one end to the other, and that floping lines be drawn alternately on each fide of it at equal diftances. Thefe lines fhould form angles of about 30 degrees (we fhould fay 40° or 45°) with the centre line, and the children be daily accuftomed to walk on it, placing their feet behind the floping lines, fo that the infide edge of the foot may exactly coincide with them. This would teach them to turn out both feet equally in walking, which they feldom do, and would give a regularity and fteadinefs to their gait, without which no one can be faid to walk well.

"By confinement in a fchool room for many fucceffive hours, and that without being fuffered to vary their pofture, fome of the more active and lively children are liable to gain tricks of involuntary actions, as twitchings of the face, reftlefs gefticulations of the limbs, biting their nails, &c. which are generally at firft occafioned by the want of fufficient bodily exercife to expend the fuperfluous animal power, like the jumping of a fquirrel in a cage; but are alfo liable to be caught by imitation of each other. To prevent this kind of deformity, children fhould be fuffered to change their attitudes and fituations more frequently, or to walk about as they get their leffons." (Darwin, p. 100.) The reader will find fome ufeful obfervations on this fubject in the chapter on Attention in Edgeworth's Practical Education.

VI. *Diet*, &c.—Under this head we fhall not find it neceffary to enter much into particulars. The food of children and youth fhould be nourifhing but not ftimulating; and as plain as can be. If their appetite be not pampered, or laid under unnatural reftraint, it will generally be their fafeft guide as to quantity. We agree with Buchan, that the error of pinching children in their food, is more hurtful than the other extreme. The diforders of repletion are lefs injurious in their confequences than the difeafes arifing from the

the want of fufficient nourifhment. Nature has many ways of relieving itfelf when overcharged; but long fafting is extremely hurtful to young people; and a child who is often pinched with hunger ftands little chance of becoming a ftrong man. "The ftomach (fays Dr. Rufh) is like an idle fchool-boy, when it has nothing elfe to do, it is always doing mifchief." When children rife an hour and half or two hours before breakfaft, we think it very defirable that they fhould be allowed a piece of bread and a draught of milk or water foon after rifing; we have perceived confiderable injury arifing in the weakly ftomach by early fafting. When they have gained fome degree of robuftnefs, this may be eafily given up. It is highly defirable that the ftomach be brought to the capacity of enduring great irregularity in the time of taking food; but in the early periods of invigoration, confiderable if not minute regularity in the principal meals is very beneficial. When children faft too long they often do not know how to eat. In fuch circumftances, a fmall quantity of warm liquid will reftore the difpofition to eat, better than dry food. The principal meal fhould be fufficiently early in the day to allow of their taking out-of-door exercife after it. Perhaps it will generally be found, that about one o'clock is the beft time for this; but it does not appear that a nearer approach to the common hour of dinner can be attended with any ferious inconvenience, if the previous time be properly arranged for it. Though children fhould not get the habit of lounging at their meals, any more than at other things, yet they fhould not be hurried at them; but fhould be induced to eat their food flowly in order that they may mafticate it properly.

We fully agree with Dr. Beddoes on the great defirablenefs of employing animal food in early childhood and ever after. Some fpeculatifts have indeed attributed the prevalence of confumptive complaints, as well as fuicide, in our ifland, to our free ufe of animal food; but it appears probable, in the firft place, that much more animal food is eaten in countries where this fatal malady occurs lefs frequently than with us; and, in the next place, that a free ufe of animal food, inftead of being objectionable, is highly advantageous as a fecurity againft its attacks. The falutary agency of animal diet in preventing the developement of fcrofula is now generally known; and the miftakes of thofe parents, who imagined that, by confining their children to a vegetable diet, they were purifying their blood, while in reality they were ftarving them into fcrofula, are now generally recognized and avoided. (Stock's Life of Beddoes, p. 168.) Cafes may occur, when animal food may be injurious; and thefe may require at leaft a temporary fufpenfion of it; but much more injury is done by a fpare or poor diet, than by a reafonably full meal of plain nourifhing food. Once a day cannot be too often for a meal in which meat fhould form a chief ingredient; and we need fcarcely fay, that its proper nourifhing effects will be moft experienced, where it is full-grown and not over-dreffed. With plenty of air and exercife, warm clothing, and moderate temperature, there is little room to be apprehenfive of injury from plenty of milk and meat. On the contrary, the beft effects on the health and vigour of the fyftem may be expected.

Profeffor Hufeland tells us, that thofe parents who accuftom their children to drink water only, render them a fervice, the value and importance of which will be fenfibly felt through life; and we fully agree with him. No beverage can be more wholefome, and we will even venture to fay on the whole more nutritious, than good fpring water. Thofe who have any acquaintance with animal and vegetable phyfiology, will not be furprifed at the laft part of this affertion. But if we leave out of view its nutritious qualities, and confider it merely as a beverage free from the noxious qualities which forcibly prefent themfelves to the minds of thofe who connect the future periods of life with the prefent, and which muft induce them to fhun the early employment of ftimulating liquors of any kind, it is invaluable. It would amply repay the parent to give up the ufe of every ftimulating beverage with his meals, for the fake of example to his children, and with a view to produce that habit of early temperance which cannot be too foon acquired. We have known the fips of wine and of ale, which many would think mere trifling indulgences, produce a propenfity to the ufe of ftrong liquors, which has been attended, even at eight or nine years of age, with intoxication. And it fhocks us to fee parents fo regardlefs of the bodily, as well as the moral health of their children, as to give them, when very young, (perhaps when three or four years of age, or even lefs,) a glafs of unmixed wine, and even urge them to drink it. Thefe fame perfons would be themfelves averfe to give their child half the wine glafs of brandy, and yet the quantity of alcohol differs little in the two cafes. Wine fhould be referved for a medicine; and there may be times, even in childhood, in which, when diluted, it may thus be ufefully employed. But in fuch cafes, with a view to the future, no pains fhould be taken to render it palatable. The true way to prevent an early tafte for ftimulating liquors of any kind, is not to make them the fubject of direct prohibition, but to keep children out of the way of them, and to accuftom them to fimple food and drink. Where the ftomach of a child is not unnaturally excited, there will be little difpofition to the ufe of fermented liquors. But if drinking them be made the fubject of boafting, or even of expreffions of lively pleafure, in the prefence of children, our precautions may be eafily rendered ineffectual. If a parent finds it neceffary to introduce to his table vifitors who will be thus carelefs of the moral welfare of the young about them, let his children take their meals in a feparate room, till he has acquired fuch power over their minds as to prevent the mental poifon from operating. Then it may be beft for him to let them be expofed to it. They muft eventually; and it is better that this fhould be done before the mind is likely to be fo much influenced by it, as it would be at the more advanced periods of youth, when the antidote will not be at hand. But before that period, if wine is to be introduced at meals, and the bottle to be circulated freely afterwards, and made the fubject of converfation, at leaft let not children be expofed to the impreffions of the fcene. Thofe who have known boys, under twelve or fourteen, habitually fond of intoxicating liquors, and taking various underhand methods to procure them, and even experiencing intoxication thus early,—who have known, too, a habit thus early begun, continued through all its ftages, till life has been prematurely cut off by its poifonous effects, when the age of manhood had fcarcely been reached,—will think no inftance of felf-denial or of prudential caution unreafonable, to prevent the poffibility of fuch evils in their own families. Whether we confider it in its prefent and future beneficial effects on the bodily organs, (the digeftive, biliary and nervous fyftems,) or in its great tendency to promote the culture of felf-controul as it refpects the corporeal defires, the habit of temperance cannot be too early begun or too fteadily purfued. Its phyfical, mental, and moral influence, its influence on health and happinefs, entitle it to a high rank among the virtues of life. At firft it will be a mere habit, formed only by parental care and influence; but as the child advances towards maturity of underftanding, every judicious means ſhould be employed, to give it the obvious and impreſſive ſanctions of prudence and of religious duty (for ſuch it has in every point of view that it can be conſidered); and theſe repreſentations will be eaſily underſtood. The proper time for introducing them, is when any ſtriking inſtances of the injurious effects of intemperance will render them impreſſive; and a few ſhort *home* ſtatements on the ſubject may then be of incalculable importance and efficacy.

With a view to ſuch ſtatements, we recommend to the judicious parent, (at leaſt if not liable to exceſſive nervous excitement,) the ſtudy of Dr. Beddoes's eighth Eſſay, on the preſervation of the phyſical power of enjoyment, including ſome remarks on food and digeſtion. They will find there "a deſcription of the ſtomach and of its various ſtates of diſtention and emptineſs, with the correſponding ſenſations by which theſe ſtates are accompanied. The progreſs of digeſtion is deſcribed in a manner ſtrikingly clear and intelligible; and this is followed by an inquiry into the principal agents by which this proceſs is impaired, and the digeſtive organs injured." The young often injure themſelves for want of proper information on the ſubject of the bodily functions; and the parent may, from ſuch ſources, derive thoſe which will enable them to render their children moſt eſſential ſervice. Dr. B. appears to us ſometimes to colour too highly; but the moſt important parts of his Hygeia we cannot doubt to be fully borne out by correct obſervation and experience. For the purpoſes of health, it appears that to take ſpirituous liquors, (whether in the form of wine or what are commonly called ſpirits,) after a meal, is of all periods the moſt improper. Proper food taken in proper quantity is exciting enough for the ſtrong, and without caution is apt to be over-exciting for the weak. Fermented liquors act with peculiar ſeverity on the tender conſtitutions of children. They ſtint their growth and impair their appetite. Numerous experiments prove this fact; and the indigent claſſes have, in ſome inſtances, availed themſelves of a knowledge of it to ſtill the cravings of that hunger which they had not the power of appeaſing by a ſufficient quantity of wholeſome food. Theſe facts ought to operate as a ſerious warning to the imprudent parent, who indulges his children in ſuch a fatal gratification. They want no ſource of artificial exhilaration to beguile their time; however it may be ſought, for thoſe purpoſes, by thoſe of more mature age, too little remembering that the pleaſurable feelings of exiſtence which ariſe from the products of vinous fermentation can only be momentary, and muſt be ſucceeded by a proportionate degree of depreſſion and at laſt of gloom. (Stock's Life of Beddoes, p. 236, &c.) The following remark of Dr. Currie (which ſhould have been introduced in Div. II.) deſerves great attention: "Though *ſpirituous liquors* may fortify the body againſt the effects of heat, combined with moiſture, and may perhaps ſupport it for a ſhort time under great fatigue, *they are, I believe, uniformly hurtful when taken under ſevere and continued cold.*"

We are not apprehenſive that we ſhall be conſidered as digreſſing on this point. That education, which, while it gives health and vigour in the early part of life, ſecures ſtrict temperance and moderation in every kind of animal gratification, is rendering a moſt eſſential ſervice to the mind and the body. The work of mental and moral culture may then be not only begun but purſued with ſteadineſs and ſucceſs; and that invaluable bleſſing, *mens ſana in corpore ſano*, will make the parent for ever recollected with the moſt lively feelings of affectionate gratitude.

We muſt revert a little more to the ſubject of *water*. To have its proper effect it muſt be *pure*. Two precautions, therefore, are to be attended to reſpecting the water which is conſtantly employed in food. The firſt is, that it be free from the oxyd (or ruſt) of lead; the other, that it do not contain too great a degree of earthy matter.

"Pure water has no action on lead; but it takes up a ſmall proportion of the oxyd of that metal. When left in contact with water, with the acceſs of atmoſpherical air, lead ſoon becomes oxydized and diſſolved, eſpecially if agitation be uſed. Hence the danger of leaden pipes and veſſels for containing water which is intended to be drank. Water appears alſo to act more readily on lead, when impregnated with the neutral ſalts that are occaſionally preſent in ſpring water." (See Henry's Chemiſtry, vol. ii. p. 89.) Vats of lead have been uſed in ſome cider countries which have produced incalculable miſchief. What is called the Devonſhire colic is occaſioned by this practice; and is identified, by its effects on the ſyſtem, with the colic of the plumbers, the painters, and the white lead makers. "Lead in its metallic ſtate, like all other metals, is probably inert; but it is ſo eaſily acted upon by the weakeſt acids and alkalies, that it cannot be taken without the moſt imminent danger." Johnſtone on Poiſons, p. 113. (See Parkes's Chemical Catechiſm.) The preſence of any quantity of lead ſufficient to produce injurious effects on the ſyſtem, may be diſcovered by an addition of the ſulphuret of ammonia or potaſh. (See Henry's Chemiſtry, vol. ii. p. 394, &c. in the chapter on the method of detecting poiſons; where alſo will be found ſome valuable remarks on this and other connected topics.) The other point is, that the water in conſtant uſe ſhall not contain too large a proportion of earthy ſubſtances. (See Parkes, p. 243.) If the water is perceived to be particularly *hard* in waſhing with ſoap, or, if in boiling it, there is a great depoſition of earthy matter on the internal ſurface of the veſſel, it is, probably, likely to have injurious effects. Boiling it would deprive it, in a great meaſure, of its earthy mixture, but it will alſo deprive it of its briſkneſs. Whether paſſing it through a filtering ſtone would take away the earthy ſubſtance we do not know; but we have known this proceſs to give rain water (by its paſſing in ſmall quantities through the air) that briſkneſs which makes water a real luxury to thoſe who habitually employ it. Probably the trouble, and certainly the expence, attending the procuring of good water from a ſpring, even at ſome diſtance, would, in general, be very much leſs than that ariſing from the employment of fermented liquors: and there would be the ſatisfaction attending the former, that it was certainly for the purpoſes of health.

It is neceſſary to ſay a few words on the ſubject of *tea*. We agree with Beddoes (ſee his third Eſſay) in almoſt every particular reſpecting it; and in this we are influenced by conſiderable experience and obſervation. We are not averſe to the uſe of it in a moderate degree and of a moderate ſtrength, eſpecially among *young men*. The habit of afternoon tea-drinking has often a cloſe connection with domeſtic diſpoſitions, and tends to ſociety at leaſt leſs injurious than that of the bottle companion. It appears alſo to furniſh, when thus limited, only a ſalutary refreſhment after fatigue of body and mind. As long, however, as the ſtomach will bear a milk breakfaſt, (which might be diverſified by uſing it in various forms,) ſo much the better. When tea is employed for breakfaſt, it ſhould be weak, cool, (little, if at all, exceeding blood heat for inſtance,) with a large proportion of milk, and as much ſugar as will render it palatable without ſickening the ſtomach, and accompanied with plenty of toaſted bread or thinly ſpread bread and butter, (in other words there ſhould be as

little

little tea as possible in the whole,) and we imagine that then no direct injury can result from it. The afternoon tea should be prepared in the same manner. If it is used in any form in which its stimulating effects are experienced it must be prejudicial to the young: and the tendency of the present employment of weak and well prepared tea, to lead to the injurious use of it hereafter, renders it desirable to keep clear of it as long as may be. Green tea possesses a power over the nervous system, which should completely prevent the general employment of it by any one. Like other strong stimulants it should be reserved for the period when it is requisite as a medicine, if there be such a one. Black tea is certainly less injurious: but even this (at least without such precautions as above stated) must affect the irritable habits of children too violently, to justify the use of it as a part of their daily diet. We recollect observing the effect of tea upon a boy of about nine or ten, (the same referred to under the head of *Bathing*,) having taken some strong green tea, with little milk and bread, and no sugar, he began about an hour and a half after to manifest excessive depression, accompanied with weeping, for a considerable time. He was, in some measure, restored to his usual tone by a comfortable supper; it is probable that as the stimulus had thus exhibited its genuine effects afterwards it had done so in the first instance by producing a temporary exhilaration.

One point connected with this head we do not wish to omit, because we deem it really important, though we doubt whether even the authority of Locke will appear broad enough to shelter us completely. The philosopher devotes five sections to the subject in his Thoughts on Education; we shall take the abridgment of them, which we find in the Parent's Friend, vol. i. p. 5.—"One thing more there is which has a great influence upon the health, which is costiveness. The contrary extreme is always attended to, and can sooner be remedied; but costiveness is harder to be dealt with by physic, as purging medicines rather increase the evil. I believe the best remedy is, for people always to solicit nature immediately after their first eating of a morning; and by this constant application they might bring it into a habit, whether they are at first called or not: and they should never let any human affairs prevent this necessary attention to their health. Children should be early accustomed to this, and should not be let go to play till they have been effectually at stool, as there is reason to suppose that many children neglect the gentle calls of nature, when they are very intent on their play."

VII. *Muscular Exercise.*—Healthy children will exercise themselves sufficiently if they are allowed: and they should be allowed, during the period when the body is the first concern, almost as much as they please; and, after that period, as much as is necessary for the vigour of the body, if it were only with a view to the vigour of the mind. They should be *encouraged* to such bodily exertions as will call into play the muscular system generally; seldom excessive or violent, but active and vigorous; proportioned in fact to the degree of strength actually possessed; and so contrived that, while it benefits the present health, and suits and excites the lively spirits of youth, it may also lay in no store of injury for the future. The last principle excludes those violent sports, which, before unusual vigour has been acquired, can scarcely fail to over-excite the system, and produce lasting injury to it. So far, indeed, from wishing to see boys and girls shrinking from exertion, or the apprehension of pain, we would have their education so conducted, that they shall be at all times ready to engage in any exercise which is not beyond their strength, and ready to undergo *any* pain that will have only an *immediate* and *temporary* effect. Those which *really* and considerably endanger the limbs, or the senses, the health, or even the lives, are what we term dangerous sports; and the danger should be early and repeatedly pointed out to children, and such sports prohibited: but all that are active, that exercise the bodily or the mental vigour and ingenuity, should be encouraged, and sometimes assisted by advice, or by the parent's taking a leading share in them. We say sometimes, because as much as possible should be left for children themselves to do. Parents should sometimes lead, but only in order to teach them to go alone: and except when this is the object, the parent will be of most service, by taking only an ordinary play-fellow's share in his children's amusements.

When children are healthy, and have been accustomed to a few simple sources of amusement, to such playthings as they can use freely, and as will call their minds into exercise, they will invent for themselves; and all that is necessary is, to give them a dry airy room in doors, and a dry airy spot out of doors, where they can play freely and actively, and to furnish them with a few implements for amusement suited to their age, such as the recollections of an active childhood will readily suggest. The rest they will generally do for themselves. A little indirect aid may sometimes be of service to give a right direction to the stimulus of their own minds; but the less direct interference the better.

We hear a great deal of boys loving play too well; and there are, doubtless, instances in which a real love of play has been attended with little or no marks of mental activity; but we see every reason to suppose, that if a boy play *well*, (with activity, spirit, and ingenuity,) it only wants proper management to make him work well. Of such a one, at least, we should ourselves never despair. If children are indolent at play, it must be from a want of sufficient animal health and spirits, and proper means should be employed to restore them to that state. A child in thoroughly good health, will, at times, be as playful, and full of anticks, as a young kitten; and without indulging that boisterous rudeness, which is inconsistent with domestic comfort, and with the necessary degrees of order and propriety, and even with the health and comfort of the children themselves, every possible indulgence should be given to their lively spirits, and to their cheerful noises.

At the period when the habit of *hardy* application is to be begun, we do not wish to see work treated as play: and, on the other hand, play should never be made work. Children may often be *led* to do, that which they have no direct inclination to begin; and a little skill in bringing about this beginning is often of real advantage. But exercise will be of the greatest use, (it will most call into exertion the physical powers, and contribute most to the health,) when it is indulged involuntarily and with spirit. Those exercises which are *expressly taught* with a view to form the limbs, and give young persons a proper command over them, must, we apprehend, be excepted (we refer to dancing, drilling, fencing, &c.); and it may sometimes be necessary, for a time, to make them compulsory; but by proper care and perseverance, they will become pleasant enough. We think highly of all these exercises. Dancing is often abused; often made the source of vanity, and sometimes even of sensuality. Exhibition-balls for children and youth we deprecate; and are satisfied that the evils attending them are many and great. The private cheerful dance, where conducted

ducted with propriety, and not carried to excefs, (by over-heating or over-exerting the fyftem, or by encroaching upon the part of the night which health requires to be fpent in bed, an hour or two before midnight,) we think a falutary amufement, good for the body and for the mind. If it have the effect the next day of producing languor and inaptitude for the common employments of life, then it has been carried to excefs.

It has been propofed to make *gymnaftics* a part of the regular bufinefs of education. A tame fpiritlefs exertion of the body is worth little. Some good may be done by it; but what fhould be the object of the parent, is voluntary active exercife, in which the whole foul is for the time engaged. The formal walk, even in the fields or on the fea-fhore, however much it may pleafe, by contraft from fedentary amufement, and which it will do only in proportion as that amufement has been kept within its due limits, cannot have nearly the fame beneficial influence on the body, or on the mind, as the lively fportive exercife which healthy children will take of themfelves. A troop of boys or girls, turned into a field to find amufement for themfelves, and left at full liberty, except that of tranfgreffing the bounds which mental or bodily health prefcribes, will do for themfelves, that which no one elfe can do for them; they will be gaining life and vigour, mufcular activity, and, what often is intimately connected with it, mental activity. Still we are difpofed to allow, that regular attention to gymnaftics fhould make a part of the fyftem of education; but then the regularity of the managment of it fhould be kept out of fight as much as poffible. The parent or the tutor may plan and lead to the execution, but the execution, and, as much as poffible, the plan, fhould originate in, or at leaft excite the ingenuity, the dexterity, the exertions, &c. of the child or youth. If children are not early allowed full employment for their bodies they may require to be taught to play; but the art employed to teach them fhould not be brought into view. In fact children teach themfelves beft; and the infpecting, controling, directing power of the older friend fhould feldom be the direct object of obfervation. He may notice in filence, and give hints from what he has feen, which will do every thing that is neceffary. Conftraint deftroys the very life and foul of play. From what we have feen of an octavo volume, entitled "Gymnaftics for Youth," tranflated from the German, we think that the parent, (under which general appellation we ufually include the tutor or parental friend,) may derive fome ufeful hints to aid him in the great and important object of bringing the mufcular fyftem into full vigour and activity. We muft by no means omit the valuable chapters on Toys and Machines, in Edgeworth's Practical Education, which every reader of this article probably has accefs to. And from extracts which we have feen from Parkinfon's Dangerous Sports, we expect that valuable cautions may be derived from it, deferving the attention of the judicious parent.

We would not have the prohibition of dangerous fports carried too far. Thofe whofe confequences may be, and efpecially thofe whofe confequences will probably be, fatal, or the injury irremediable, fhould be abfolutely prohibited, and the difpofition to avoid them produced by confiderations of prudence and benevolence. Forced exertions beyond the ftrength, blows on the head, ftomach, &c. injury in the eyes from any caufe,—thefe, and all others coming under the above defcription, fhould be the fubject of frequent caution. But in real life occafions continually occur, in which pain muft be borne, or in which fome degree of rifk muft be run; and that education muft be radically defective, which does not fow the feeds of fortitude and prefence of mind. Nothing will teach thefe qualities but expofure to pain and fome degree of danger. We do not mean a voluntary direct expofure; but we would check that exceffive caution on the part of the parent, which fhuns prefent fuffering at the expence of future ftrength of mind. The benumbing influence of fear injures beyond calculation; and though we have no wifh to fee foolhardinefs, which is bold becaufe it is unacquainted with the real extent of the dangers it runs into, we do always rejoice to fee in a lad firm endurance of pain, and active boldnefs, under the guidance of fome little prudence and ingenuity in extricating himfelf from rifk, without paying more attention to the danger than is neceffary to efcape from it. Cowardice is fo often, we might fay fo conftantly, the fource of meannefs, and all its accompanying vices, and (even where the moral education has checked thefe) is fo often a bar to valuable exertions for the good of others, that every indication of it fhould lead to proper methods to eradicate it. Some may fuppofe that all that is neceffary is to give ftrength and health. So far from fortitude being a neceffary attendant upon thefe, we have feen reafon to confider it as a more conftant companion of activity of mind, united with lefs robuftnefs of body. Activity is the grand point; this will lead a boy into rifks, (we do not mean of fatal accidents, but of fuch as for the time may be painful,) and the fame activity will often fuggeft expedients to efcape from them; and the more this is done in early life, the more felf-command and prefence of mind will be practicable, when neceffarily expofed to great and imminent danger. Prefence of mind, as Mifs Edgeworth has well obferved, is, in reality, abfence of mind, as far as the danger is concerned: on that it does not dwell, but upon the expedients of efcaping it. And it muft require uncommon mental culture in the later period of life to acquire this invaluable quality, where fear has been the habit of the earlier.

The little accidents of childhood and youth fhould not receive too much fympathy. All that is neceffary for their relief fhould be done, at leaft in the earlieft ftages of education; but the little mind fhould be excited to bear its pain, by pleafantry, or even raillery, by appeal to fhame, by turning the attention from it, in fhort by any and by various methods, thofe being felected which experience has fhewn to be moft effectual for the individual. After the firft period of childhood, their accidents fhould receive very little direct attention; the parent will obferve, but the obfervation need not be made to excite their notice. He fhould be ready to ftep in where neceffary, but in common cafes leave them to act for themfelves. Indeed this is one grand object in education, to enable the individual to act for himfelf, when the great bufinefs of life depends upon his own wifdom and exertions.

When the dread of pain (even where the mind is unfupported by fympathy, or not ftimulated by the dread of fhame) is in a confiderable degree fubdued, or made inactive, (in other words, when fortitude has been acquired,) there is only one thing more requifite for effectual prefence of mind, and that is a knowledge of the beft methods of efcaping danger, a readinefs of invention, and the adoption of means to ends. Thefe are more intimately connected with the culture of the imagination and the underftanding. To produce them, the young fhould often be led to confider what is beft to be done in accidents of different kinds. "What would you do if your clothes were on fire?" we would afk a girl old enough to underftand and to act. "What would you do if your brother fell into the water, or fell down and broke his arm?" are queftions which would lead to ufeful converfations with a boy. When occurrences of of this nature are mentioned, the mind of an intelligent youth may be fet to confider what fhould have been done, and then compare it with what was done. Where this turn is given to the inventive powers, highly ufeful refults might be expected, not only when in actual danger, but in providing againft the accidents of human life for others. Newton Bofworth's little book, entitled Accidents of Human Life, will furnifh fome ufeful hints; and it would be well to keep a common-place book for this exprefs object, which might be ftored with facts of actual occurrence, and with fuggeftions as to probable cafes in future. An acquaintance with the ftructure and functions of the body, with chemiftry, and with mechanical philofophy, cannot fail to be of great ufe for this object, and attention to them with this object in view, will be of fervice in others. Our readers will find fome hints which may be of fervice in INTELLECTUAL *Education*, Div. V; and ftill more towards the clofe of Mifs Edgeworth's chapter on Attention. The excellent little dialogue in Evenings at Home, called Prefence of Mind, well deferves the perufal of parents as well as children.

To any one who fairly confiders the way in which the bodily and mental faculties are developed, it will appear abundantly clear, that exercife is as much required for the one as for the other; and as the mental progrefs fo much depends upon the health of the body, even if that be to be regarded as the primary object, this muft on no account be neglected. "Exercife is neceffary for health, bodily and mental," fhould be the fundamental maxim of every fyftem of education private or public. It is a law of our natures, againft which no one can offend with impunity; and fuch arrangements fhould be adopted in every fchool, and in every domeftic plan, that it may be fully and effectually obeyed. Sedentary employments fhould be frequently relieved by active mufcular exertion. It is a bad thing for the mind to be kept on the ftretch too long; and, therefore, fedentary amufements are often neceffary; but fedentary amufements fhould only be reforted to where active fports cannot be had. Bodily activity is almoft an effential requifite for mental activity, and indifputably for the full enjoyment of health. If from any circumftance the fchool hours exceed two or at moft three hours at one time, let a break be made at fome convenient place for "a good batch of play." Little will be loft by it for the time; much will be gained for the future. Exercife out of doors, where dry good air can be had, is, in every point, greatly to be preferred; but where the rain and chills of our climate will not permit, ftill let it be had within.

When children have been fitting fo long, that they feel indifpofed to bodily exertion, there is no doubt they have fat too long.—"Like every other organ, the palate and the ftomach, when left inactive and unirritated, lofe their original faculties. Repeated fafting is fatal both to appetite and to digeftion. Sedentary occupations," we would fay too long continued, and difproportioned to the age and degree of mufcular maturity, "gradually deftroy the defire, and impair the power, to exert the mufcles, more particularly while they are forming."—"To debar children from giving loofe to thefe inclinations, by indulging which, they knit their finews, fwell their mufcles, and harden the whole againft the viciffitudes of air, is a kind of feverity neither indifferent to them or to thofe about them, for the prefent or for the time to come."

It really appears fomewhat unneceffary to dwell upon this fubject as we have done; and yet it is difficult to meet with any plan of education into which it enters as it ought. In making the above quotations from Beddoes (Eff. iii.) we obferve, that in his plan for a girl's fchool, which we think in many points very judicious, (though clearly formed more with a view to *weakly* children, than could in general be defirable for girls and ftill lefs for boys,) he lays down the following precept: "under twelve years of age it fhould be an invariable rule, that the hours of application fhould never exceed thofe of amufement and exercife." The principle is a good one; and it fhould not much be departed from, till the period when application becomes voluntary and pleafant; and then fome portion of the hours for *amufement*, we do not include thofe of *active exercife*, may be added to thofe of application. We are inclined to think that, in general, for boys between ten or eleven and fourteen, nine hours fleep, eight hours work, and feven for meals, exercife, and amufement, is a good divifion. Thofe, who fee reafon to adopt our views in INTELLECTUAL *Education*, efpecially under the heads of *Attention* and *Memory*, will be of opinion, that Dr. Beddoes' plan is in thefe points radically defective. It affords ufeful hints, but it cannot be followed, we apprehend, and at the fame time mental *vigour* be obtained.

But while we fay this, we muft add, that we deprecate, as he does, exceffive mental exertion in children. The phyfical fyftem muft be the firft object. If the order of nature be reverfed, the mind will eventually fuffer for it, as well as the body. It would often be eafy for the fkilful parent to make a child a prodigy; but the judicious parent never will attempt it. Premature and luxuriant growth of mind will feldom, if ever, be found to fpring from a vigorous root. It will be viewed by thofe, who know the laws of human nature, as a difeafe; and fuch it will generally prove, even in the eftimation of the mere fuperficial obferver. We do not doubt, that many have funk into an early grave, through the unnaturally rapid developement of their faculties, and the exceffive excitement of mental and phyfical fenfibility, which is ufually the caufe or effect of it: and ftill more have had the progrefs of their bodily health and ftrength impaired; their minds have funk into a ftate of ftagnant liftleffnefs; and the promife of early genius has been completely difappointed, and followed by a train of phyfical and mental and moral evils, which fhould ferve as a beacon to the vain or the unwary.

Though this article is expanding beyond our wifhes, we cannot forbear prefenting our readers with another extract from Search. The Light of Nature may not be acceffible to many; and this paffage is truly important, and deferves to be carefully weighed by every parent.—"Nor is it enough to reftrain fleep within due bounds, if the waking hours be fuffered to dream away in a torpid indolence not much different from fleep. It is of great fervice, even to the health, to cultivate a fpirit of activity, continually exerting itfelf in fome exercife either of body or mind. The former is more neceffary for the animal machine, and for that reafon deferves to be particularly regarded for fuch as are deftined to follow fome fedentary profeffion, that they may be inured by early cuftom never to fit ftill with their hands before them in the intervals of bufinefs, but to move brifkly in their common actions, and daily to practife fuch recreations as may keep the circulation to its proper flow, and prevent ill humours from gathering in the blood.

"Yet an activity of mind, too, is not ufelefs to the body; there being fuch an intimate connection between the groffer and finer organifations, that irregularities in the one, will not fail to produce their like in the other. There are fome who love to fit in a corner, building caftles in the air, mufing upon improbabilities foothing to their fancy, and wifhes of what can never happen, or perhaps upon fomething that has vexed them, or the imaginary dread of mifchiefs never likely to befall them; though this may feem an intenfenefs of thought when the mind is rather too bufy than too remifs, it is in reality not an activity, but paffivenefs bound down to an object rifing mechanically in the imagination. Tempers of this caft have a perpetual liftleffnefs and dilatorinefs, they apply to nothing readily, they do nothing currently, but want to put off every thing another minute, even their meals, their diverfions, and their beloved nightly repofe. Such ftagnation of thought, become habitual, muft inevitably introduce a like ftagnation of the vital juices, fret and wafte the fpirits, generate fearfulnefs and melancholy, and impair the health more than will be eafily imagined.

"This mifchief then deferves an early attention to obviate, the more becaufe difficult to be difcovered in its beginnings; for we cannot penetrate into the thoughts to fee what paffes there: but before grown inveterate, it will fhew itfelf in the actions, or rather in the inertnefs of difpofition; and then no time fhould be loft to cure it, nor any means omitted that can be devifed to teach children to find an iffue for their thoughts by running them in current trains, and to take pleafure in making good difpatch of every thing, as well in their tafks as their amufements.

"Neverthelefs it muft not be forgotten, that there is a contrary extreme, which urges to make more hafte than good fpeed; a continual hurry and agitation, never fatisfied but when in motion; an impatience to do things before the proper time, and eagernefs to difpatch them at once by a violent exertion; an over-folicitude for the fuccefs of meafures, and a vexation upon any rub happening to fall in their way. This temper likewife is unfavourable to the health; for mifchief will enfue upon precipitating the circulation of blood and animal fpirits, as well as upon retarding it. A calm and fteady alertnefs, flowing in one uniform tenour, always brifk and lively, never anxious nor trepidating, is the defirable point to be purfued: therefore, we muft fo labour to cure one evil, as not to incur another; and keep an eye upon Scylla, while we endeavour to fteer clear of Charybdis. I know it is a difficult matter, perhaps impoffible, to hit exactly the golden mean; but we fhall come the nearer, by being apprifed of dangers on either hand: though I think the former is the greater, the more frequently fallen into, and harder to be cured. The beft that can be done muft be by diligence in watching the approaches of either, and applying the proper remedy as foon as they are perceived."

In what we have faid, we wifh to be underftood as referring, unlefs otherwife expreffed, to girls as well as to boys. We are fully fatisfied that there is a conftitutional difference in the fexes, which is perceptible even from infancy; and that the parent, who fhould train up her daughters to all the moft robuft exercifes of boys, would find that fhe had carried the matter too far. But we are alfo fatisfied, that this conftitutional difference is unneceffarily and moft injurioufly carried beyond all the bounds of nature, in the common modes of educating girls. We recommend to mothers, efpecially, fome remarks on this fubject in Reflections on the prefent Condition of the Female Sex, by Prifcilla Wakefield; a writer who has contributed well to ftore the children's library with works containing really ufeful information. "How often," fhe fays, (we quote from Parent's Friend,) "has our anxiety for the delicacy of the complexion, or the apprehenfion of her becoming a romp, reftrained a girl from the indulgence of enjoying either air or exercife, in a fufficient degree, to fecure her from that feeble, fickly, languid ftate, which frequently renders her not only capricious, but helplefs through the whole courfe of her life. There is no reafon for maintaining any fexual diftinctions in the bodily exercife of children. If it is right to give both fexes all the corporeal advantages which nature has given to enjoy, let them both partake of the fame rational means of obtaining a flow of health and animal fpirits, to enable them to perform the functions of life."—"Employment fhould be contrived, on purpofe to induce them to pafs a large portion of their time in the air; nor fhould they ever be permitted to fit within long at a time. A mere walk fcarcely fupplies fufficient exercife to produce a quick circulation; fomething, therefore, more active fhould be adopted. Running races, trundling a hoop, fkipping with a rope, battledore and fhuttlecock, ball, jumping, dumb bells, fwinging, and many other amufements of the like nature, are fuitable for the purpofe, and may with equal propriety be practifed by both fexes, being by no means incompatible with delicacy of perfon and manners. Let it never be forgotten, that true delicacy confifts in a purity of fentiment, and is as much fuperior to its fubftitute, external manners, as a real gem to one that is artificial."

VIII. *Exercife of the Senfes.*—It is certainly poffible to have eyes, and yet not fee; and to have ears, and yet not hear. This, however, is in general more owing to the fluggifhnefs or inattention of the mind, than to the imperfection of the external organs of fenfe. Impreffions on the organs of fenfe, which, if the attention of the mind were actively directed to them, would convey clear, vigorous, and well-defined fenfations, may either excite a mere partial or fleeting notice, or pafs away without any fenfation whatever. See *Mental* PHILOSOPHY, Div. I.; and in connection with other topics of this divifion, the reader will probably find fome advantage in confulting Div. II. alfo.

In INTELLECTUAL *Education* we have endeavoured to mark the diftinction, which is too feldom obferved, between *fenfations* and *perceptions*; and we fhall not enter upon the fubject again. The reader will find the firft four divifions of that article bear clofely upon what may well be termed the mental proceffes of perception, and we beg leave to refer him to them for this purpofe. Dr. Reid, in his Effays on the Intellectual Powers, has a diftinct chapter on the improvement of the fenfes (Effay II. chap. 21.); but from the views which that philofopher took of the nature of perception, it might be expected, and it is accordingly the fact, that he fays but little on the improvement of the *fenfes* properly fo called: it is principally on the improvement of the perceptive power. The philofophical reader may, however, find it worth while to confult that chapter; and the judicious, but inexperienced mother will alfo derive much ufeful information from the fecond and third letters in Mifs Hamilton's fecond volume.

That the perceptive power is fufceptible of very great improvement, by proper exercife and culture, there can be no doubt; but fome may doubt whether this is the cafe with refpect to the bodily organs of fenfation. When it is confidered, however, that improvement, as the confequence of due exercife, is the grand law of our phyfical and intellectual powers, it might be inferred that the external organs are, by the fame means, fufceptible of improvement, in furnifhing correct and vivid fenfations. And when it is confidered that even well-formed healthy infants indicate little fenfibility of fight and hearing for many days; that there are manifeft and great differences in the animal tribe, in the powers of fenfation; that even where there is the power of vigorous attention, children greatly differ in the correctnefs and vividnefs of their fenfations; that thofe who are accuf-

tomed

tomed to obferve objects of a certain clafs, not only have much more ready and accurate perceptions, but even can at once difcern, where fenfation only is concerned, what very clofe attention will fcarcely enable another to fee; that thofe who are deprived of one of the three organs of intellectual fenfation, acquire a peculiar fufceptibility, not only of perception, but of fenfation from the others; and that at the period of natural decay, and even earlier, there is a great diminution of the power of fenfation; it appears to us fcarcely to be doubted, that the bodily organs of fenfation are fufceptible of great variation and improvement in the fame individual.

Even if this fhould ftill be regarded as matter of theory, it is obvious that no effort in endeavouring to improve the fenfes can be loft: for by the fame means we fhall be effectually improving the faculty of perception. And, on the other hand, whatever means are taken to exercife the perceptive power, thefe will, upon the above principle, cultivate alfo the organs of fenfation. The exercife of the bodily organs, and accurate attention to the impreffions upon them, are, in fact, the only direct means by which this laft object can be effected. The indirect means are of indifpenfible importance, and will do much towards rendering the direct means of real efficacy: we refer to thofe means by which the bodily health, vigour, and activity, are to be obtained. The exercife of bodily vigour, and efpecially of bodily activity, not only has the effect of ftrengthening the nervous fyftem generally, and of giving it a *healthy* fenfibility, but it furnifhes conftant exercife for the organs of fenfation. The ufeful playthings of childhood and youth, and their employment out of doors, are continually calling thefe organs into activity; and that agility in mufcular movements, with which health and activity are fo often attended among the young, and which contributes fo much to give bodily dexterity, is peculiarly ferviceable in calling into play the power of fenfation alfo. Dexterity does of courfe imply the quick and vigorous fenfation, and accurate attention to it, and the ready affociation with it of the appropriate mufcular movement; and where it is exercifed, there the organs of fenfation muft alfo be exercifed. In fhort, wherever and however the attention is directed to the objects of perception, whether in the way of fimple obfervation, or of comparifon and difcrimination, the correfponding organ of fenfation is undergoing a proper culture.

Hence a great deal may fafely be left to the mere influence of external objects, provided the attention is pretty fteadily and frequently led, directly or indirectly, to the perceptions. A child who obferves much, muft acquire quicknefs of perception; a child who obferves accurately, muft acquire accuracy of perception, and confequently muft acquire quicknefs and accuracy of fenfation. But there are few cafes in a judicious education, in which all will be left to this indirect exercife. During the plays and employments of childhood and youth, various means may be devifed of calling the fenfes into activity, and directing the attention to them. In the book which we before referred to, "Gymnaftics for Youth," there are fome ufeful fuggeftions refpecting the method of artificially exercifing the fenfes, which we think may be ferviceable to fome of our readers, and which we fhall give in the form in which we find them in the "Parent's Friend."

"Befides the natural exercife of the fenfes, I think it might be poffible, by artificial means, to increafe the power of each fenfe, in the fame manner as hundreds of deaf and blind perfons, who fupply, to an aftonifhing degree, the lofs of one fenfe by the zealous cultivation of another. Accordingly, in exercifes of this kind, fometimes the eyes fhould be covered, fometimes the ears prevented as much as poffible from hearing, fometimes the reft of the fenfes kept as free as may be from impreffions. When children have acquired confiderable readinefs by the natural exercife of the fenfes, in their eighth or tenth year perhaps, I confider it as a very pleafing and ufeful occupation to exercife them artificially in the following manner." Though the author fpeaks of the age of feven or nine as a proper time for the artificial exercife of the fenfes, it is obvious that it may be begun with advantage at a much earlier period. In fact, it can fcarcely be begun too early. But, throughout, it fhould be conducted as little as poffible in the way of a formal bufinefs. The exercife of the mufcles, and the exercife of the fenfes, fhould be made as interefting as poffible, and feldom employed except in the way of amufement.

(1) "*Exercife of the Touch.*—The much greater promptitude of the fight and hearing, evidently leads us to neglect the fenfe of feeling; whence I am induced to think, that this deferves our greateft attention. The eyes are to be previoufly covered, and then let the perfon fo blindfolded difcover perfons by feeling their faces or hands; diftinguifh coins; tell what a perfon writes in the palm of the hand with a pencil or point of a fkewer; diftinguifh the leaves of all kinds of trees and plants with which he is acquainted; eftimate the degree of heat, air, and water according to the thermometer; diftinguifh plates of polifhed metal, of fimilar figures, by their fpecific heat; eftimate the weight of various fubftances in pounds, ounces, and the fmaller weights; tell all kinds of wood, and the different productions of the loom; eftimate the number of leaves in a book and tell the pages; among a number of leaves of the fame kind of paper, feparate the blank, written, and printed; write; eftimate the length of various fticks in feet and inches, the fuperficies of a table, the folid contents of fubftances of regular figures, and the capacities of different veffels; mould eafy figures, mathematical for example, in clay or wax, paying attention to the fize as well as the form; make pens, and cut out various objects; diftinguifh all kinds of fubftances put into his hand, as chalk, fealing-wax, &c.: let him endeavour to feel infcriptions in relievo, as upon large coins.

(2) "*Exercife of the Sight.*—Let him eftimate every relation of magnitude as it exifts in nature; length, breadth, height, depth, fuperficies, folidity, and diftance: both in the great, as yards, furlongs, miles; and in fmaller dimenfions, as feet, inches, lines. The conjecture fhould always be compared with actual meafurement. This will at the fame time afford a pleafing mode of practically acquiring the art of menfuration. On fultry days, for which more violent gymnaftic exercifes are not fo well adapted, I have often had recourfe to thefe, and found that young perfons very foon acquire a confiderable readinefs in them. It is above all things neceffary to imprint as deeply as poffible on their minds accurate ideas of the different meafures. When this is done, they will foon learn the art of applying them in all directions, and thus meafure with the eye. Let him draw all kinds of mathematical figures without compaffes or ruler, divide lines into a given number of parts, cut meafures of feet, inches, and lines upon fticks, copy mathematical figures in perfpective from models, draw fchemes for them, cut them in paper, and put them together. All this muft afterwards be examined by mathematical inftruments, and the errors corrected. Let him take for a pattern a picture, on which are many different fhades of colour; compound every fhade in it from the feven primary colours, and lay them all down upon paper; or let him merely declare of what colours each fhade is compofed. Let him eftimate the weights of

various bodies by looking at them. Let him ſtop his ears with his fingers, and hold a converſation by obſerving the motion of the lips.

(3) "*Exerciſe of the Hearing.*—The youthful company, in which the fewer there are the leſs noiſe is to be apprehended, being all blindfolded, their maſter will do various things, and they muſt tell what he is about; in other words, he will occaſion ſome noiſe in different ways, and they muſt explain whence the noiſe ariſes. This admits of great variety. All common actions, ſuch as walking, writing, making pens, and the like, are eaſily diſcovered; accordingly the maſter will proceed to ſuch as are more unuſual, for inſtance ſtepping upon a chair, or ſitting down on the ground. When theſe are diſcovered, with tolerable facility he will go farther. He will bid them gueſs the figure, ſize, and ſubſtance of things by the ear. For example, whence proceeds that ſound? from a glaſs, a baſon, a bell, a piece of iron, ſteel, copper, ſilver, wood, the table, or the bureau? Of what ſize, and of what ſhape it is?

(4) "*Exerciſe of the Smell and Taſte.*—A perſon blindfolded may diſtinguiſh flowers, various articles of food, many metals, leaves of trees, freſh, and in many caſes dry pieces of wood, and ſeveral other ſubſtances, by the ſmell alone, without touching them, and moſt of them by the taſte."

IX. *Senſibility.*—The ſenſe of touch deſerves to be regarded as diſtinct from the general ſenſe of *feeling*, which, with the exception of thoſe of ſight, hearing, ſmelling, and taſte, refers to every ſenſation experienced in any part of the body, either from internal or external impreſſions, and upon which principally the phyſical ſenſibility depends. We do not mean that when the nervous ſenſibility in general is great, there will often be found deficiency in the organs of ſight, hearing, &c.; but that what is well termed *ſenſibility*, both phyſical and mental, depends principally upon the organs of feeling. Now the great object with reſpect to theſe is, not to rouſe them to irritability, by direct or exceſſive excitement; or to produce that irritability by methods which cannot be unattended with eſſential injury to the bodily health, ſuch as over-exertion of mind, want of air and exerciſe, exceſſive warmth, &c.; but, on the contrary, to bring the ſyſtem into, and to preſerve it in, that ſtate in which the ſimple natural pleaſures of feeling (the pleaſures of health, of activity, &c.) are enjoyed, and in which there ſhall be no unnatural tendency to the pains of this ſenſe. How great a ſhare theſe have in producing the mental pains, may be underſtood by the remarks on this ſenſe in *Mental* PHILOSOPHY, Div. II. And on the ſubject of this ſection, we wiſh to refer the reader to *Moral* EDUCATION III. 10. 11. 12.

The general law of the *ſenſible* pleaſures and pains is, that by ſimple repetition they loſe their vividneſs, and their effect upon the mind: and the ſame is the caſe with the mere paſſive *mental* feelings. Yet it is of great importance to be borne in mind, in early education, and in the individual's ſelf-culture, that where any part of the ſyſtem of feeling is unduly called into exerciſe, it increaſes the irritability of the whole; that the phyſical powerfully acts upon the mental ſenſibility, and this in turn upon the phyſical ſenſibility; that whatever increaſes the pleaſures of ſenſation beyond their natural ſtate, muſt alſo increaſe the ſuſceptibility of the ſenſible pains; and that the influence of theſe upon the happineſs, (where they ariſe from, or are accompanied by, an exceſſive irritability of the nervous ſyſtem,) far exceeds that of the ſenſible pleaſures ariſing from ſuch exceſſive excitement of body or of mind.

One grand object of the early period of education ſhould be, to bring the phyſical ſyſtem into its due ſtate of health, vigour, and activity. If this be ſucceſsfully purſued, all is done which is requiſite for the proper regulation of the phyſical ſenſibility. All the means which we have heretofore ſuggeſted, if employed judiciouſly and ſteadily, have the direct tendency to give the nervous ſyſtem its due tone; to make ſenſations have their proper influence in the intellectual ſyſtem, and to keep them from having too great influence in the ſyſtem of internal feeling. On the one hand, theſe means will tend to correct that extreme nervous irritability which might indeed be employed ſucceſsfully to produce a rapid and premature developement of the faculties and affections, but which cannot be called much into play without ſapping the foundation of the health of body and of mind; and, on the other, they will ſupply the beſt phyſical prevention of the formation of that morbid ſenſibility which ſo continually fixes the mind upon its own feelings, which implants ſelfiſhneſs in its moſt refined, perhaps, but moſt ruinous forms; and which ſeeks for gratification, or at leaſt relief, in that unnatural excitement which only feeds the corroding irritability of the ſyſtem, and muſt by degrees deſtroy the capacity of enjoyment, and plunge in perhaps irretrievable calamities. The early and external means for the cure or prevention of exceſſive ſenſibility, muſt however be ſupported by internal aids. A diſpoſition to active exertion,—a love of order and regularity, (which we deem of incalculable importance,)—a taſte for mental employment not exciting to the mind, but engaging its attention, and calling into play and ſtrengthening its various powers, in their due meaſure and degrees,—a diſpoſition which will turn the ſenſibility which exiſts into the channel of benevolence and piety,—fortitude with reſpect to perſonal pains,—patience with reſpect to perſonal privations,—and the habit of ſelf-controul early checking or preventing that wild hankering after mere pleaſure which never yet did any thing but harm, afterwards called into exerciſe, and ſupported by reaſon and religion, to prevent every ſenſual gratification which prudence and duty forbid,—theſe cannot fail of being attended with the moſt beneficial effects on the health and happineſs: they will conduct the youth to the maturity and vigour of his bodily powers, and of intellect and affection: they will enable him and prompt him to act well his part in life with uſefulneſs to others, and with honour and comfort to himſelf: and we need not ſay that they will ſerve as a noble foundation for religious excellence.

The following paſſage contains a picture of "that morbid ſenſibility which renders exiſtence in many inſtances an almoſt uninterrupted ſeries of painful ſenſations," which ſhould make thoſe concerned in education do what they can to prevent ſuch dreadful evils. It is true it is an extreme caſe; but thoſe who have had occaſion to obſerve the appearances of morbid ſenſibility in leſs extreme and too common ſtates, will perceive, that, in their degree, the features of the picture belong alſo to them. "That the dropping of a hair-pin on the floor ſhould make a perſon ſtart from her ſeat, and fix her in a preternatural poſture, by occaſioning preternatural fixed contractions of the muſcles, or agitate her by contractions and relaxations equally preternatural, till ſhe ſinks into inſenſibility, from which ſhe awakes into vehement delirium, is hardly credible to thoſe who are converſant only with the healthy, and the ſorts of ſickneſs to which the robuſt are ſubject. On comparing an individual liable to theſe ſad varieties of being, to the engineer who ſtands unmoved amid the thunder of a battery; to the ſeaman who maintains his footing upon the deck, or ropes of his veſſel reeling under the ſhock of the elements; or to the

the Indian who exhibits the ſigns, and probably feels the throb, of intenſe delight, while the flames are preying upon his fleſh; how aſtoniſhing do we find the range in human ſuſceptibility to the effect of the powers by which we are ſurrounded! how important is it to conſider the cauſes of the difference, if on the one hand we ſhould have as much reaſon to ſuſpect that reſiſtance to pain may be united in the higheſt degree to capability of pleaſure, as we have, on the other, to be perſuaded that thoſe who have become in ſo high a degree ſenſitive, are nearly loſt to all but painful emotions; and that if their organs are like wax in being impreſſed by external appulſes, they too often reſemble adamant in retaining what impreſſions they may receive." Beddoes, as quoted by Stock, p. 252.

Inſanity, melancholy, epilepſy, palſy, and a whole train of evils, are the attendants upon an undue, exceſſive, and long continued excitement of the nervous ſenſibility; and it ſhould be one leading object of education, among females in particular, ſo to direct their employments, their amuſements, their diet and temperature, their waking and their ſleeping hours, that their conſtitution may be hardened, their bodies and minds invigorated, and the beſt chance given them for meeting the unavoidable evils of life, ſo that theſe may promote their moral improvement, without inflicting upon them unneceſſary ſufferings, or deſtroying their powers of uſefulneſs. With this view, it may be laid down as a maxim in education, that whatever ſtrongly excites the ſenſibility, without connecting it with active exertion, whatever, in ſhort, increaſes the diſpoſition to paſſive pleaſure, is, and muſt be, injurious,—injurious to the health of the mind, and alike injurious to the health of the body. To make ſuch ſickly ſenſibility the ſubject of approbation is folly in the extreme.

How the ſenſibility, in its natural ſtate, ſhould be turned into the channel of benevolence, we have endeavoured to ſhew in MORAL *Education;* and the reader will find ſome judicious obſervations on the ſame topic in Miſs More's Strictures. With reſpect to girls, what in general is moſt wanting is, to check their ſenſibility, or at leaſt to give it its proper direction. With reſpect to boys, it may ſometimes be neceſſary to excite their *mental* ſenſibility; but in general, where proper pains have been taken early in life, the benevolent affections will have ſufficient vividneſs and vigour: and at any rate they ſhould never be enlivened by ſtimulating the ſenſibility of the nervous ſyſtem. A boy ſhould, if poſſible, be kept from the feeling that he has nerves; if we find his affections and intellect ſtrong and vigorous, that is all we can wiſh for.

X. *Purity.*—The work of education has, indeed, an extenſive ſcope; and no department of it can be neglected without injury to the reſt. Phyſical education is of the firſt importance in the earlieſt periods; but if it be even then made an excluſive object, the conſequences muſt be highly injurious. An unreſtrained mind in a vigorous body, as we have already obſerved, will be the moſt likely to ſink into the loweſt moral depravity, and eventually to deſtroy, by this means, the object to which ſo much care and exertion had been devoted. Without attaching any importance to the number *ſeven*, as pretending to ſet limits, which, in a great variety of inſtances, muſt be merely arbitrary, the interval between birth and manhood may be conveniently divided into three periods, of ſeven years in each. During the firſt (unleſs the imagination of a child has been allowed to gain an exceſſive preponderance, and the elements of deſire have riſen to an enormous height) there muſt be uncommon impurity in the language or actions of thoſe around them, if the conceptions or deſires have, in any degree, a ſexual complexion. But during the ſecond, (more eſpecially if children aſſociate much with others *older* than themſelves, who are not under the reſtraints either of delicacy or decency,) it is an unhappy fact, that long before there can, in the order of nature, be any proper ſexual deſires, there is not unfrequently a degree of indecency in language and manners, againſt which the parent, who is anxious for the moral welfare of his children, ſhould moſt ſedulouſly guard. We have known this to be the caſe, even where boys have been brought up at home, having been allowed, however, to mix with thoſe who themſelves had little moral controul; and we ſee reaſon to think it particularly the caſe at thoſe ſchools where boys of the ſecond period are allowed a free intercourſe with thoſe of the third. Hence we admire the plan which appears to be gaining ground, of ſchools for boys from ſix to twelve. If they are thoroughly well regulated, under the ſuperintendance of able perſons, and they give eſpecial care to the prevention of impurity in language, &c., the moſt beneficial ends may be anſwered. Perhaps even a progreſs in the languages might, upon an average, be made in ſuch ſeminaries as ſatisfactory as at ſchools upon the uſual plan; the rudiments of other valuable branches of knowledge would be gained more effectually; and, above all, the moral culture of the mind might be carried on with much greater ſucceſs. As far as our experience goes, it is more difficult to reſtrain the impure language of young boys, whoſe minds have received an early taint, than of older ones, unleſs, indeed, the diſeaſe has taken a deep and alarming root. In the former caſe it is extremely difficult to inſtil that ſenſe of impropriety, which, where there is any moral feeling, may be produced in this connection, ſoon after the age of puberty. Some may think that great care on this ſubject is a refinement of ſqueamiſh delicacy, and not a neceſſary precaution of moral purity; we are however ſatisfied that ſuch will not be the opinion of thoſe who have ſtudied the laws of the human mind, or who have obſerved the power of words over the conceptions of the imagination and the excitement and the direction of the deſires. That power is beyond all calculation, and often beyond all controul. The caſual imagery of the fancy will paſs away, and unleſs the mind intentionally dwells upon it, cheriſhes it, and endeavours to recall it, it may even leave no veſtige to bring it back again into view; the mere corporal feeling, unleſs unhappily inflamed by external ſources of impurity, may eaſily be brought into ſubjection. But when words have been much or long aſſociated with ſuch trains of conceptions or feelings, they will, in various ways, contribute to excite and to ſtrengthen them, and the conſequence will often be that purity will be loſt, and that the moral, mental, and phyſical ſyſtem, will ſuſtain ſhocks from which they cannot recover.

It is one moſt injurious effect of that exceſſive reſerve which parents often think neceſſary on theſe ſubjects, that their children are left without any definite knowledge of the miſchief which the language of indecency will inevitably produce. Let the parent acquire his child's full confidence, and let him, with no other end in view, than his moral welfare, early give him judicious warning, and repeat this as often as he may think neceſſary to revive the impreſſion, and the beſt effect will follow.

We preſume not to offer much advice on this ſubject to *mothers*. A mother poſſeſſed of genuine delicacy of mind will not need it; and to others we could be of no ſervice. A daughter grows up ſo much more under her mother's

 eye,

eye, than a ſon can do, and there is, we doubt not, among all but the moſt abandoned of the female ſex, ſo much more of that "decent *perſonal reſerve* which is the foundation of true delicacy of character," that we hope it can require but common judgment and common care to preſerve her purity of mind. A mother who knows, however, the moral dangers of the female ſex, even where the general laws of chaſtity are not violated, will be on her guard in obſerving every poſſibility of expoſure to them; ſhe will guard the plant of modeſty with aſſiduous care, and will be watchful to preſerve it from the noxious influence of the indelicacy of rude ignorance or of impurity. We have reaſon to think that mothers ſometimes allow their daughters a more unreſtrained intercourſe with ſervants, or with companions of ſuſpicious delicacy, than prudence can authorize. They never ſhould be expoſed to circumſtances which may lead them to offend againſt "decent perſonal reſerve." How much the preſent too common modes of dreſs will leſſen that feeling, every conſiderate mother muſt perceive. What thoſe moral dangers are to which we referred, beyond thoſe of impure language, and how fatally they have been experienced, we think a father anxious for the welfare of his daughter, will take proper means of acquainting her to whoſe foſtering care they are to owe their ſafety. Beyond what we have ſuggeſted, we can merely add, that the books which lie in the way of girls of the ſecond period, not only ſhould not be of that kind which muſt cheriſh a ſickly ſenſibility, but ſhould be free from every thing at which genuine modeſty would bluſh. And if a viſitor ſhould, in their preſence, bring forward ſuch ideas, however clothed in the language of elegance, or refined double entendre, he ought to be excluded from their ſociety. That a father ſhould ever do ſo ſeems impoſſible: we wiſh it were.

But the delicacy we wiſh to ſee, "is ſomething nobler than innocence." It is not the delicacy of ignorance, but the purity of imagination and deſire. And we are ſatisfied that this is, in ſome inſtances, beſt preſerved by a knowledge of the ſimple truth. "The ridiculous falſities which are told to children from miſtaken notions of modeſty, tend very much to inflame their imaginations, and ſet their little minds to work reſpecting ſubjects which Nature never intended they ſhould think of, till the body arrived at ſome degree of maturity. Children very early ſee cats with kittens, birds with their young, &c. Why then are they not to be told, that their mothers carry and nouriſh them in the ſame way? As there would then be no appearance of myſtery, they would never think of the ſubject more. Truth may always be told to children, if it be told gravely; but it is the immodeſty of affected modeſty that does all the miſchief; and this ſmoke heats the imagination by vainly endeavouring to obſcure certain objects." Parent's Friend, vol. i.

Thus far we preſume to ſuppoſe we have not offended againſt our own principle. We have hitherto written for parents indiſcriminately; but what follows is deſigned for the eye of the father; aud we muſt here be allowed a little more minuteneſs.

We do not doubt that the due regulation of the ſexual deſires is, on the whole, the greateſt difficulty in education. The danger of doing too much is, in ſome caſes, almoſt as great as the danger of doing too little. But the circumſtances of the times, including ſocial intercourſe, newſpaper communications, &c. are ſuch, that nothing, we think, but the blindneſs of ignorance, or the careleſſneſs of vice, or the exceſſive caution of unenlightened or indolent timidity, can heſitate in endeavouring to communicate ſuch impreſſions reſpecting the nature and conſequences of an illicit or unnatural indulgence of thoſe deſires, as may operate altogether to prevent, or moſt materially to check them.

How early ſuch communications ſhould be made, is a matter of extreme difficulty. We recollect hearing a father ſay, that he had ſucceeded in producing in the mind of his ſon, before the age of puberty, ſuch a deteſtation of the vice we have more particularly in view, that he felt a full confidence as to his moral reſtraint. In that proceſs we have as yet had no experience; but we are inclined to ſuppoſe, that more will be effectually done by giving only general, though perfectly diſtinct, cautions, reſpecting language and actions connected with this ſubject, and by leaving the more impreſſive repreſentations till the period when the deſires will ſtand moſt in need of reſtraint.

Before the age of twelve, a father will often be able to perceive, in a well-educated boy, the indications of decided moral principle; by which we underſtand the real and actuating deſire to do right, and to avoid every thing wrong. When beſides this he has reaſon to have confidence in his ſon's purity of mind, (we ſtill mean of imagination and deſire,) and alſo in his prudence, we think a ſimple judicious communication reſpecting the delicate ſtructure, and the object of the male organs, would be attended with important advantages. This would lead to a few plain, but impreſſive ſtatements, reſpecting the highly injurious and often fatal conſequences of the abuſe of them; and the neceſſity of ſtrictly avoiding every thing, in word or action, which might lead to ſuch abuſe. With theſe repreſentations, the father who has ſucceſsfully cultivated the principles of religion in his ſon's mind, would add ſuch as would connect with every kind and degree of impurity, the idea of its offending his omniſcient heavenly parent. If it have previouſly been his object to communicate intereſting information reſpecting the ſtructure and functions of the human frame, ſuch a communication as we have mentioned will have no appearance of formality; and it may be introduced by a natural digreſſion from ſome other connected topic. Some ſuggeſtions as to the mode of accompliſhing it may be obtained from Dr. Beddoes's fourth Eſſay; but we would make it a much more ſimple buſineſs. It will require no more knowledge of anatomy, than what any judicious well-informed father may eaſily gain from different articles of this work, or the common works on the ſubject; though if he had an injection of the veſſels preparing and conveying the ſeminal fluid, this aided by plates ſhewing the *internal* ſtructure of the urinary and ſeminal organs, could not fail to produce a ſalutary fear of injuring that which ſimple inſpection would prove to be ſo complex and ſo delicate.

We need not ſay, that whatever determination he adopt on this difficult point, he muſt do his beſt to keep off from his ſon thoſe impreſſions, (from books, pictures, converſation, &c.) which may tend to give a premature excitement to his deſires, or to feed them when they ſpring up in the courſe of nature; and as he cannot altogether ſucceed in this, he will endeavour to render them powerleſs, by ſuch repreſentations as may make them rather ſhunned than foſtered. A parent with any juſt ſenſe of duty, cannot fail to avoid himſelf communicating ſuch impreſſions, or permitting them to be made under his own eye; "Nil dictu fœdum viſuque hæc limina tangat Intra quæ puer eſt," ſhould be inſcribed in his memory, and made his invariable principle. It is indeed a noble one; and alike important.

With the ſame object in view, he will ſeduloufly (yet without any formal precepts,) endeavour to prevent all breaches

breaches of that decent perfonal referve of which we have fpoken; for inftance, at the times of bathing, wafhing, attending to the calls of nature, &c. We do not want to fee affected fqueamifhnefs, often hiding real indecency; but genuine delicacy and purity. And he will alfo obferve, (with this fpecific object in view, *viz.* to keep the fexual defires as near as poffible within the limits of nature refpecting time and ftrength,) thofe rules which common prudence and experience fuggeft, refpecting fimple diet, active exercife, early rifing, &c.

But we will fuppofe a cafe in no degree uncommon; that no communication has been made to a youth refpecting the evil we have already alluded to, and that his father, or a parental friend, fee reafon to believe, that all his *indirect* caution has been ineffectual, and that the deleterious practice has been begun which will gradually impair his bodily and mental powers; and, if not prevented in time, will plunge him into irretrievable evils. Can there be any hefitation what courfe to purfue? Can there, then, be a doubt as to the neceffity of opening his eyes to his fituation? It muft be done with prudence; but we know it may be done with fuccefs; and we know, too, that the refult may be earneft affectionate gratitude for the communication, and heartfelt fatisfaction at having been the means of preferving a fellow creature from the moft ferious calamities.

Whether the communication fhould be in converfation or by letter, muft be decided by the circumftances of the cafe; we have known each tried. On the whole we fhould prefer opening the fubject by converfation. It will then be more eafy to perceive whether the caution had been neceffary, and to what degree. After fome interval, a paper might be put into the hands of the youth, containing a brief, but diftinct, and impreffive ftatement of the dreadful confequences of the practice; and fome fimple cautions to aid in checking the tendencies of the mind to it. If this produced its proper effect, it would fcarcely be neceffary, for a confiderable interval, to revert to the fubject; but then it might, at leaft, be expedient. It is, however, by no means defirable to bring it frequently forwards; for though it may be treated as a moral difeafe, yet there muft be a feeling of delicacy (or perhaps we fhould fay of fhame) attending it, which could not be worn off without ferious injury; add to which, the efficacy of the reprefentations made would leffen by too much repetition. Thofe external indications which furnifhed the firft ground for apprehenfion, muft, however, be the guide in determining the fubfequent fteps. The difficulty is in the commencement. And we fhould add, that in the firft converfation every means fhould be employed, to prevent all converfation on the fubject with others; it fhould be abfolutely confined to the individual and his friend.

The parent or tutor may take every preventive caution, (exclufive of direct communication,) may do every thing that enlightened prudence would fuggeft to preferve ftrict perfonal referve, and keep off the contagion of evil example; and all this completely, and in itfelf confidered fuccefsfully; and yet without preventing the evil. Many inftances have been known of its commencement without any communication with others, and by circumftances in fome fenfe accidental. We are fully fatisfied, taking every thing into account, that it would be beft to *forewarn* every boy who poffeffed a tolerable fhare of good fenfe and moral fufceptibility. Numerous inftances have occurred, in which this practice has been begun and perfevered in, till the mifchief was almoft, if not altogether, irretrievable, without the individual's having been fully fenfible of the criminality, and but little of the moft injurious confequences, of "this fpecies of flow fuicide."

For the mode of commencing the fubject after there were decided grounds of apprehenfion, we can give no fpecific directions. We can only fay, that it muft be done at a fuitable time; when the mind feems open; when nothing has occurred to excite fufpicion as to the motives; and with that cautious referve which may give an infight into the real ftate of the cafe. Then is a time to give a faithful reprefentation of confequences, &c. A paper for the purpofe already fuggefted, might be of fome fuch nature as the following, which may affift in the firft ftages alfo.

We would begin by mentioning, (without of courfe the flighteft perfonal allufion,) fuch cafes as had occurred to our own knowledge, where lofs of fight, total lofs of mental and bodily health, and premature death, had followed the continuance of it; and where extremely debilitating involuntary emiffions had fucceeded the habitual practice of it, even where it had been abandoned. We would then felect fuch compreffed ftatements from books of authority, (and we have feen Tiffot often referred to, and in Dr. Beddoes's fourth Effay will be found a ftriking cafe, which will urge every confiderate parent to early communication,) refpecting the common effects of this wafte of a fluid defigned to anfwer fuch important ends in the animal economy, and the early and exceffive lofs of which muft weaken the whole nervous and digeftive fyftem, impair the faculties of the mind, and furrender the wretched victim of fenfuality to the miferies, infirmities, and decrepitude, of extreme yet infirm old age. We would inform him that it would fubject him to convulfions, epileptic fits, palfy, infanity, impotency, tabes dorfalis, corporal emaciation and decay, and partial or even total blindnefs or deafnefs; and that where the progrefs to thefe calamities had been checked in time, the mental and bodily faculties are ufually fo injured by any long continuance of it, as to become incapable of any valuable exertion. We would farther tell him, that the bare ftatement of the natural and neceffary effect of this deftructive practice, was fufficient to fhew the will of God refpecting it, even if it do not appear to be exprefsly forbidden in the fcriptures. That it is included in ftrong expreffions of a more general nature, (fuch as Rom. xiii. 12—14. 1 Cor. iii. 16, 17. 2 Cor. vii. 1. Gal. v. 19—21. 1 Pet. ii. 11., and efpecially 1 Cor. vi. 9—10.) there can be no doubt; and at any rate that God has forbidden it by the ufual courfe of providence. That its moral effects in deftroying the purity of the mind, in fwallowing up its beft affections, and perverting its fenfibilities into this depraved channel, are among its moft injurious confequences; and that they are what render it fo peculiarly difficult to eradicate the evil. That in proportion as the habit ftrengthens, the difficulty of breaking it of courfe increafes; and that while the tendency of the feelings to this point increafes, the vigour of the mind to effect the conqueft of the habit gradually leffens. We would tell him, what we remember a medical profeffor faid, that whatever might be faid in newfpapers refpecting the power of medicine in fuch cafes, nothing could be done without abfolute felf-controul, and that no medicines whatever could retrieve the mifchiefs which the want of it had caufed. And that the longer the practice was continued, the greater would be the bodily and mental evils it would inevitably occafion. We would then advife him to avoid all fituations in which he found his propenfities excited, and efpecially, as far as poffible, all in which they had been gratified; to check the thoughts and images which excited them; to fhun thofe affociates, or at leaft that converfation, and thofe books, which have the fame effect; to avoid all ftimulating food and liquor; to fleep cool on a hard bed; to rife early, and at once; and to go to bed when likely to fall afleep at once; to let his mind be conftantly occupied, though not exerted to excefs; and to let his bodily powers be actively employed, every day, to a degree which will make a hard bed the place of found repofe. Above all, we would urge him to imprefs his mind, (at times when the mere thought of it would not do him harm,) with a feeling of horror at the practice; to dwell upon its finfulnefs and moft injurious effects; and to cultivate, by every poffible means, an habitual fenfe of the conftant prefence of a holy and heart-fearching God, and a lively conviction of the awful effects of his difpleafure.

When entering into the world, where temptations of a different nature will neceffarily occur, we would, before his leaving the roof of the parent, then enter into other branches of moral reftraint. On this point, however, we have had an opportunity of faying enough already; fee *Moral* PHILOSOPHY, II. I. 2. 3. to which we refer the reader.

At the clofe of MORAL *Education*, after a reference to the fuggeftions we have now brought forwards, we expreffed our intention to introduce in this article "a comparative view of the advantages and difadvantages of public and private education." Since this feries was commenced, we have, at different times, paid fome attention to the fubject; but ftill without the ability to draw up fuch a view as would prove fatisfactory to the reader or to ourfelves. We fhall once more defer it, and hope to offer it under the head of SCHOOLS.

Since the former part of this article was fent to the prefs, we have had an opportunity of hearing Syer's Treatife on the Management of Infants ftrongly recommended by a profeffional man, as a truly excellent work; and we think it our duty to mention it for the benefit of our readers. On the fubject of this laft divifion, fome ftriking obfervations will be found in a fingular work, entitled "The firft Lines of a Syftem of Education, according to Philofophical Principles."

PHYSICIAN, a perfon who profeffes the art of preventing and curing difeafes. At prefent the appellation is ufually limited to perfons who poffefs the degree of doctor, or bachelor of medicine, and who do not practife chirurgical operations; fince cuftom has introduced this divifion into medical practice.

The profeffion of curing difeafes, however, is very far from being confined to thefe two claffes, phyficians and furgeons: for, in modern times, both thefe claffes are greatly outnumbered by the apothecaries, or difpenfers of medicines, who have, in the courfe of years, gradually become medical advifers, and have undertaken both the counfel and management of the fick, and the manipulation of remedies. Or perhaps the divifion may have originated by an oppofite progreffion, in proportion as men of liberal education and enlarged views took up the inveftigation of the human conftitution, and by carrying the principles of fcience to the mere art, at once augmented the utility of the profeffion, and gave dignity to the purfuit. The acquirements which are neceffary to form the accomplifhed phyfician, are, indeed, not comprifed within a fmall compafs, and are therefore only to be attained by a careful cultivation of the underftanding for a feries of years; for without the preparatory and collateral information, the mere medicinal knowledge will, in general, lead but to a blind routine in the fteps of the mafter, and to a limited and often erroneous application of a few unvarying precepts. A curfory view of the qualifications of the medical character may perhaps, therefore, not be out of place here; the hiftory of the progrefs of medical opinions and improvements having been already detailed. See MEDICINE, *Hiftory of*.

All the works of nature are fo intimately connected, that no one part of them can be well underftood, by confidering and ftudying it feparately. In order, therefore, to be qualified for the practice of phyfic, a variety of branches of knowledge, feemingly little connected, are neverthelefs neceffary. The early ftudies of an individual deftined to the profeffion, fhould be of that liberal nature which tend to enlarge the views, and to cultivate the reafoning faculty, and a talent for obfervation; for that quicknefs of perception and readinefs of refource fo neceffary in the emergencies which often prefent themfelves in practice, can only be perfected by a clear and methodical arrangement of ideas and an extenfive knowledge.

Independently of the improvement of the faculties and the refinement of tafte, which are derived from the ftudy of the ancient languages, the fources of a phyfician's information muft be very limited, if he is not mafter at leaft of the Latin tongue, which has been the univerfal language of the learned in Europe for fo many ages, and ferves as the medium of communication between all nations on the fubjects of fcience. The labours of the ableft medical philofophers of Italy, Germany, and France, can only be participated through the medium of that language. The fame actual neceffity may not exift for a knowledge of the Greek language: but an acquaintance with that copious, expreffive, and harmonious tongue, in which fome of the oldeft, and fome of our beft authors have written, particularly Hippocrates, the father and founder of medicine, could fcarcely be difpenfed with, even if almoft all the medical terms of art were not derived from it. Ignorance of this language muft therefore impede the progrefs of the medical inquirer; nor can it be deemed becoming a phyfician to be in the daily ufe of terms, to the original of which he is a ftranger. The progrefs of medicine and the collateral fciences in France, which during the laft half century has been recorded in the vernacular language, renders a knowledge of that tongue now indifpenfible; and an acquaintance with the German is daily becoming the key to much valuable knowledge.

Thus prepared with the means and inftruments for acquiring information, the phyfician muft deem a knowledge of the following fciences effential to his profeffion. The neceffity of a previous knowledge of *anatomy*, or of the ftructure of the human frame, to the practitioner of medicine is obvious. That very minute acquaintance, however, with the ramifications of every arterial branch, and with the courfe and infertion of every mufcle, fo neceffary to the furgeon, who is employed to divide and remove different parts by the knife, is fcarcely requifite to be retained in the recollection of the phyfician. To him a correct knowledge of the fituation, appearance, ftructure, and connection of the more important organs is, however, not to be difpenfed with. The beft anatomifts, like the beft mechanifts of watches and other machines, will be beft able to replace or remove what is morbid or deranged, *i. e.* will be neceffarily the beft *operating furgeons;* but it is obvious that the perfon beft acquainted with the ftructure of parts, not to be approached by mechanical means, is not neceffarily the greateft adept in afcertaining their difeafes, which are learnt from a knowledge of *fymptoms* only, nor of curing them by the indirect operation of medicines.

For the purpofe of afcertaining the feat and nature of the difeafes diseases of parts not under the view of the eye, nor within the reach of the hand, the two branches *physiology* and *pathology* are requisite: and these, especially the first, comprehend various other branches of knowledge which might appear unconnected with them.

Physiology comprises the doctrine of all the functions of the animal body in its healthy state; as well as of the nature and composition of the fluids, their production, uses, and discharges. For the proper comprehension of these matters, the whole range of *natural philosophy* is indispensibly necessary. "When you inquire into this subject," says Dr. Gregory, "you find the human body a machine, constructed upon the most exact mechanical principles; in order, then, to understand its movements, you must be well acquainted with the principles of *mechanics*. Considering the human body in another view, you find fluids of different kinds circulating through tubes of various diameters; the laws of their motions, therefore, cannot be understood without a knowledge of *hydraulics*. The eye appears to be an admirable optical machine; and of course the phenomena of vision cannot be explained without a knowledge of the principles of *optics*. As the human body is surrounded with an elastic fluid, the air, subject to various changes in respect of gravity, heat, moisture, and other qualities which have great influence on the constitution, it is proper to be acquainted with the nature and properties of this fluid, the knowledge of which constitues the science of *pneumatics*. It were easy to bring many more examples to shew how necessary a knowledge of the various branches of natural philosophy is to the right understanding of the animal economy." See Dr. John Gregory's Lectures on the Duties and Qualification of a Physician, p. 73.

But there are many other phenomena of the animal economy, which are not explicable on the principles of mechanical philosophy. Various changes are induced upon the fluids, which chemical science can alone explain. The production of different fluids from one source, their qualities and nature, are not indeed as yet fully ascertained; but chemical analysis affords the only source of investigation. It is, therefore, necessary to be acquainted with the chemical history of our fluids; and still more requisite to know the chemical qualities of numerous substances which are taken into the human body as food, drink, medicine, and poison. The necessity of a knowledge of *chemistry*, therefore, previous to the study of the practice of physic, is obvious.

Yet the most accurate knowledge of anatomy, of mechanical philosophy and chemistry combined, will be insufficient to explain all the phenomena of the animal economy. The animal machine differs in many important circumstances from an inanimate one. An internal principle directs and influences most of the operations of the body, by a set of laws totally distinct from, and independent of, any principles of mechanics or chemistry hitherto known. It possesses the power of motion within itself, and even of modifying and resisting the operation of ordinary chemical agents: it has likewise the power of removing its own disorders, and of rectifying many deviations from its natural state; as in the case of fractured bones, of the incarnation of wounds, of the enlargement of one organ when another is destroyed, &c. It must be obvious, therefore, notwithstanding the many attempts that have been made to explain the phenomena of the animal body upon mechanical and chemical principles alone, that such a doctrine must be altogether imperfect.

A new and interesting investigation, therefore, presents itself to the physiologist, and one of the most intricate and difficult pursuit; namely, an inquiry into the laws of the *nervous system*, or of that faculty of living beings which has been called the *vital principle*, *sensorial power*, *nervous energy*, *&c.* (See EXCITABILITY, and LIFE.) On this power depend all the faculties of sensation and motion; the phenomena of the circulation of the blood from the moving powers of the heart and arteries; those of respiration, and the changes which that function produces on the blood, on the brain and organs of sense, and on the temperature of the body; and, consequently, the phenomena of digestion, absorption, nutrition, secretion, (as of bile, saliva, tears, urine, &c.), and excretion (as of the intestinal fæces, of perspiration, mucus, &c.), which are the result of the circulation of the blood. In order to illustrate the nature of these functions of the human body, a knowledge of the *comparative anatomy* of other animals is requisite. Many important discoveries in the animal economy have originated in experiments first made upon brutes, which could not have been made upon the human subject; for example, the experiments relating to the circulation of the blood, respiration, muscular motion, the sensibility and irritability of different parts of the body, and the effects of various medicines.

It belongs, moreover, to physiology to trace the diversity of the human constitution in different individuals, circumstances, and climates, arising from age, sex, manner of living, and original temperaments or habits of body; inasmuch as diseases are much influenced, as well as the operation of remedies, by these varieties. For the same reason, it is also requisite to inquire into the laws relating to the mutual influence of the mind and body upon each other. This leads to an extensive and interesting subject, the history of the faculties of the human mind; which, if we are not on our guard, is apt to carry us insensibly into a labyrinth of metaphysics. How important, however, the study of these laws is to the physician, may be demonstrated in considering the power of habit, the effects of enthusiasm, the force of the imagination, and the influence of the principle of imitation, on the functions and diseases of the body. See HABIT; IMAGINATION, *Influence of*, *on the Corporeal Frame*; and IMITATION, *Principle of*, in *Medicine*.

All these branches of knowledge, however, may be considered as preliminary to the great object of the physician, which is the discrimination and cure of diseases. When he is well acquainted with the nature and functions of the living body in its healthy state, he will be prepared to investigate them in a state of disease. *Pathology*, which delivers the general doctrine of the causes, symptoms, and effects of diseases, is obviously built upon *physiology*. The mode in which the seat and nature of diseases are to be ascertained from their symptoms and progress, and the indications to be deduced from them, have been detailed at length under the proper head. (See DISEASE.) The general doctrines to be observed in the cure of diseases, and the general nature of the remedies to be employed, constitute the *therapeia*, or *therapeutics*; which comprises a knowledge of the *Materia Medica*, or of the substances, natural and factitious, that are administered to the sick, and of their qualities and effects. In this branch of medicine, the necessity of a knowledge of *chemistry* is again apparent, since many of the most active and valuable agents are the products of this art; and the science of *botany*, so far as it facilitates the knowledge of the plants which are used n diet or medicine, is likewise subservient to therapeutics.

Thus copiously stored with all the information above alluded to, the physician is prepared to acquire experience, by observing the various symptoms of diseases, and the operations of medicines, during his attendance on the sick: and let it be remembered, that it is only upon such a foundaa foundation that real *experience* can be built. Experience does not confift in *feeing* a great number of difeafes: for if it were fo, the beft phyfician in the world would be an old nurfe in a large hofpital, who fees the daily and hourly progrefs of every fpecies of malady. Yet how contracted the views, how limited the refources of fuch a perfon! how mechanical and unvarying are the few rules of practice which are thus acquired! Yet fuch is, in fact, the fum of the *experience* which a whole life of practice affords to thofe who prefume to enter the profeffion of medicine, without that preliminary education, which alone fits the mind for *obfervation*, the only foundation of true experience. A perfon may be taught many of the practical arts of life, to a certain extent, without any knowledge of their principles. He may learn to navigate a fhip, in a certain courfe, with little knowledge of the principles of navigation; or he may make a dial without any acquaintance with aftronomy, or fpherical trigonometry: fo he may be taught, behind the counter of an apothecary's fhop, half a dozen apozems for the cure of a cough or a diarrhœa. But order fuch a navigator to fteer a new courfe, or fuch a diallift to take a new afpect; and from a total deficiency in the *firft principles* of their refpective arts, they are altogether unable to fucceed. Still more difficult is it to be fuccefsful in the cure of difeafes, without a knowledge of firft principles; becaufe the circumftances of difeafes are perpetually varying; and the fame fymptom, a cough or diarrhœa for inftance, are indicative of very different ftates of difeafe, and will be materially injured in one inftance by the very remedy which proved curative in another. (See COUGH.) Throughout the practice of medicine, indeed, a refort to general principles is perpetually neceffary, fince no two cafes of difeafe are exactly fimilar. Many difeafes, it is true, are obvious in their caufes, appearances, and treatment, and, if not actually mifmanaged, have a natural tendency to terminate in health; but on the other hand, many ferious maladies affume at firft a common form, and it requires no little fagacity to trace them in the bud, and no little knowledge to obviate their fatal confequences.

It is not, however, enough to poffefs knowledge; but the mind fhould be able at once to bring in review the knowledge which it retains, and fhould be ready and active in its application. It is often neceffary to adopt at once a plan, and to purfue it with active decifion: it is neceffary to weigh contending difficulties, and at once to feize the path where the feweft or leaft important appear, or where the inconveniencies are counterbalanced by the advantages. It is not always eafy for the obfervers to eftimate the value of fuch decifion in the phyfician; for this rapidity is often equally the offspring of ignorance: becaufe no difficulty can be experienced by thofe who are not able to anticipate confequences; and doubt, the confequence of different refources contending for fuperior eligibility, can fcarcely be felt by thofe who have no plan at all. Phyficians are called on, in general, to act with this prompt decifion; and to hefitate is ufually accounted a mark of ignorance. A man muft have merited the confidence of the world before he can claim time for confideration, and his reputation muft be firmly eftablifhed, before he can own himfelf at a lofs. This neceffary readinefs of refource is partly owing to habit and experience, but principally to a methodical arrangement and clear diftinct views of the knowledge treafured in the mind. The able and experienced phyfician, who can at once comprehend the object to be attained, will, at the fame moment, perceive the various methods by which it can be effected, and he has only to chufe the moft convenient and the beft adapted to the habit or idiofyncrafy of his patient. In his progrefs new views will probably open, and the foundeft judgment is fhewn in fteering between the oppofite extremes, of varying the plan according to the variety of fymptoms, or obftinately perfifting in it, notwithftanding every change of appearances. The firft is pleafing to common obfervers, as it fhews a diligent attention; but it is a proof of weaknefs and indecifion. The laft, perhaps the moft venial error, is the effect of too great confidence; and, unlefs accompanied with extenfive knowledge which dictated the firft opinion, and an acute fagacity in difcerning the effects of medicines, is fcarcely lefs injurious.

It feems obvious, then, that a complicated art, like that of medicine, can only be acquired by the union of extenfive information, with diligent obfervation, and that much evil is likely to enfue where it is practifed without thefe qualifications. Abfurd as is the notion of univerfal remedies, or of any given remedy for any one difeafe nominally the fame, the extent of quackery feems, however, to be increafing, partly from the revenue which government derives from it, but very much alfo from the acknowledged imperfection of the medical art in the hands of fo many half-qualified practitioners. To conclude, however, in the words of that able and eftimable phyfician before quoted; "On the whole, it will appear, that a phyfician, who underftands the principles of his profeffion, who has an extenfive acquaintance with every branch of natural knowledge connected with it, who properly applies his knowledge, and who has genius and attention equal to others, muft have a great advantage, as a practical phyfician, over one who is ignorant of the principles of medicine, and of the fciences connected with it. Genius and fenfe are, indeed, the peculiar gift of heaven, and cannot be acquired by the moft extenfive learning, or the greateft efforts of induftry. But with thefe affiftances, genius and fenfe are capable of the higheft improvements." Gregory's Lectures, before quoted, p. 87. See alfo Parr's London Medical Dictionary, art. *Medicine;* and Percival's Medical Ethics.

PHYSICIANS, *Dogmatical*, called alfo *rational*, among the ancients, were thofe who endeavoured to reduce their knowledge of difeafes to certain principles. The *dogmatic* phyficians were in oppofition to the *empirics*. See EMPIRIC.

PHYSICIANS, *Empirical*, properly fignify thofe who rely upon experience, and are directed by it in practice. An ancient fect of this appellation was oppofed to the *dogmatic* or rational fect; and the principles of both are admirably detailed and criticifed by the elegant Celfus. De Medicinâ, Præf. See EMPIRIC.

PHYSICIANS, *Methodical*, a fect of phyficians of Rome, who refufed to adopt the doctrines either of the dogmatic or empiric fect. See METHODISTS, in *Medical Hiftory*.

PHYSICIANS, *Galenical*, a diftinction affumed by thofe phyficians after the revival of learning, who prefcribed only vegetable medicines, and their preparations. They ftood in oppofition to the *chemical* or *fpagirical* phyficians, who employed the preparations of metals and minerals procured by chemiftry. See GALENICAL.

PHYSICO-MATHEMATICS, includes thofe branches of phyfic, which, uniting obfervation and experiment to mathematical calculation, undertake to explain the phenomena of nature. See *Mixed* MATHEMATICS.

PHYSICS, PHYSICA, φυσικη, derived from φυσις, *nature*, fometimes alfo called *phyfiology*, and *natural philofophy*, is the doctrine of natural bodies, their phenomena, caufes, and effects, with their various affections, motions, operations, &c.

Mr.

Mr. Locke would likewife have God, angels, and fpirits, comprehended under phyfics; but thefe are more ufually referred to metaphyfics.

The immediate and proper objects of phyfics, are body, fpace, and motion.

The origin of phyfics is referred by the Greeks to the Barbarians, *viz.* the Brachmans, Magi, and the Hebrew and Egyptian priefts.

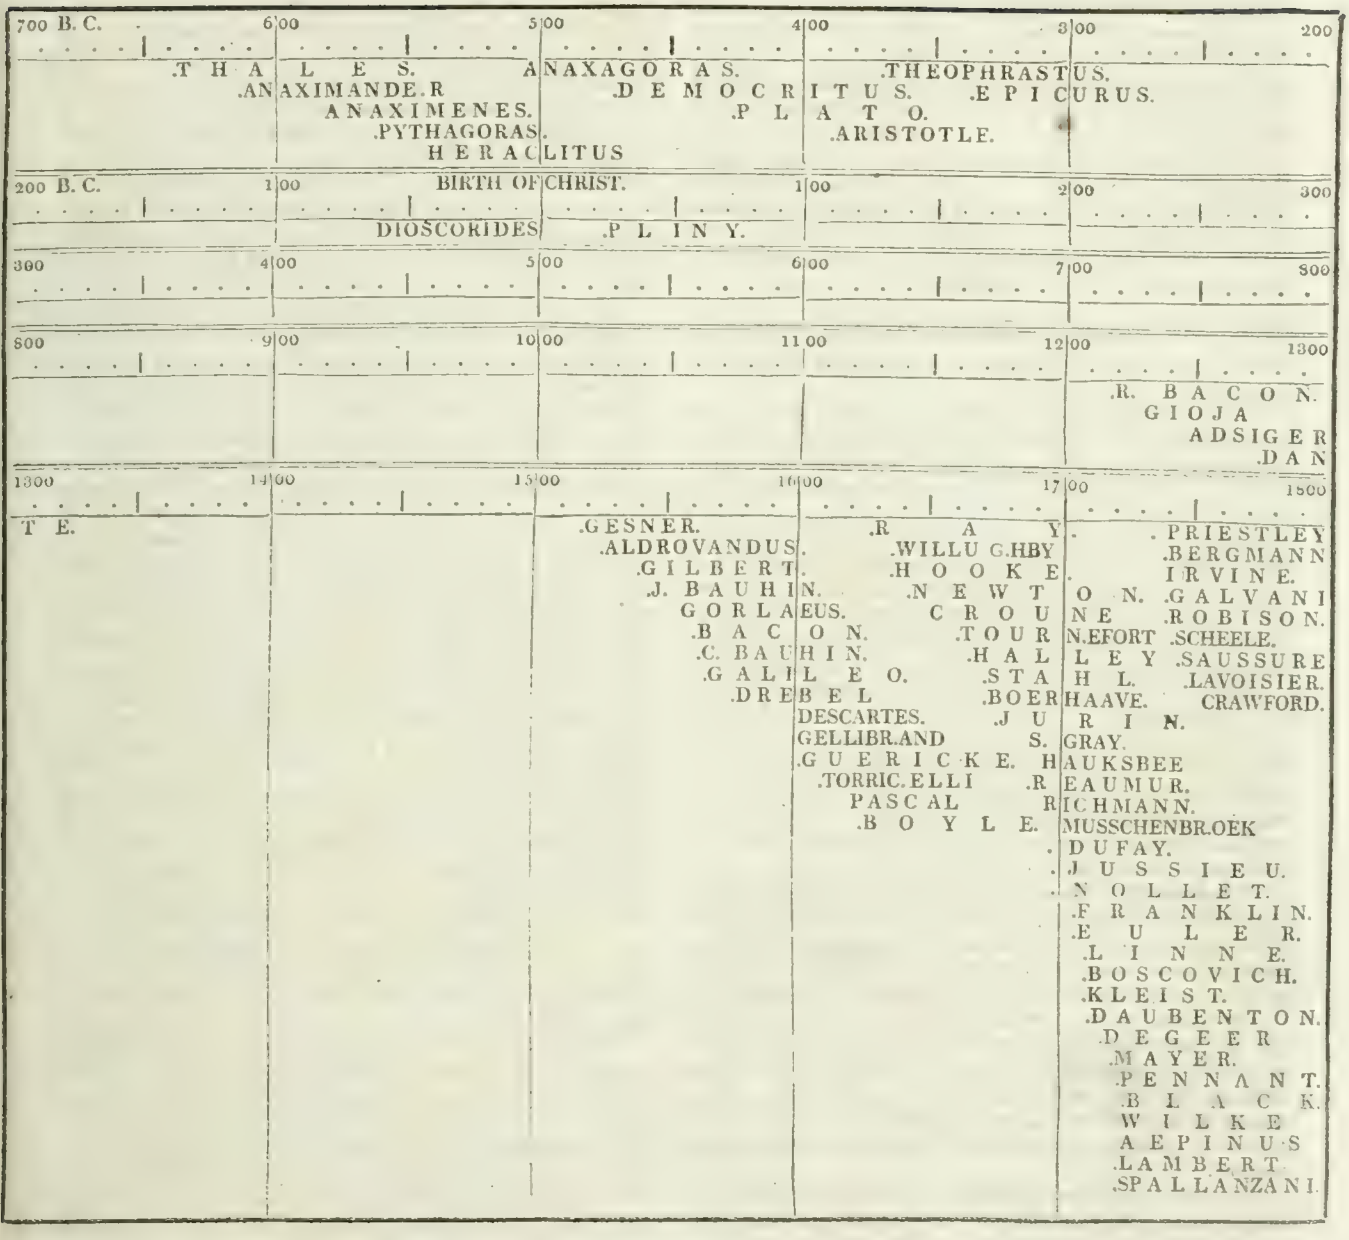
From thefe it was derived to the Greek fages or fophi, particularly to Thales, who is faid to have firft profeffed the ftudy of the phenomena of nature in Greece. He fuppofed water to be the general principle from which all material things are formed, and into which they are refolved: he particularly noticed the properties of the magnet, which had been before obferved to attract iron, as well as the effect of friction in exciting the electricity of amber; and to both of thefe fubftances he attributed a certain degree of animation, which he confidered as the only original fource of any kind of motion. (See THALES.) Anaximander (fee his biographical article) appears to have directed fome attention to meteorology; he derived the winds from the rarefaction of the air produced by the operation of heat; and he attributed thunder and lightning to the violent explofion or burfting of the clouds, which he feems to have confidered as bags, filled with a mixture of wind and water. The fame erroneous notion was entertained by Anaximenes (fee ANAXIMENES), who compared the light attending the explofion, to that which is often exhibited by the fea, when ftruck with an oar. Pythagoras is faid to have reafoned on phyfical effects in a manner too mathematical and vifionary to entitle him to be ranked among thofe who have inveftigated the minute operations of nature. (See PYTHAGORAS.) For the opinions of Anaxagoras and Democritus, fee their refpective articles. Thales had fuppofed water to be the firft principle of all things, and Anaximenes air. Heraclitus fixed on fire as the bafis of his fyftem, attributing to it the property of conftant motion, and deriving all kinds of groffer matter from its condenfation in different degrees. (See HERACLITISM.) It is obferved by Bacon, in his effay on the opinions of Parmenides, that the moft ancient philofophers, Empedocles, Anaxagoras, Anaximenes, Heraclitus, and Democritus, fubmitted their minds to things as they found them; but Plato made the world fubject to ideas, which he fuppofed to exift independently of the human mind, and of the external world, and to compofe beings of different kinds, by their union with an imperfect matter. Ariftotle made even ideas, as well as other things, fubfervient to words; the minds of men beginning, in thofe times, to be occupied with idle difcuffions and verbal difputations, and the correct inveftigation of nature being wholly neglected. Plato, however, entertained fome correct notions concerning the diftinction of denfer from rarer matter by its greater inertia; and it would be unjuft to detract from the extraordinary merit of Ariftotle's experimental refearches, in various parts of natural philofophy, and more efpecially from the information contained in his works on natural hiftory. Ariftotle attributed to fire abfolute levity, and to the earth gravity, confidering air and water as of an intermediate nature. (See PLATO and ARISTOTLE.) For an account of the opinions of Epicurus, fee EPICUREANS. The works of the ancients, though fcarcely any one of their opinions and conjectures was fcientifically eftablifhed on fure foundations, furnifh neverthelefs a variety of detached facts and obfervations, that have either led to modern experiments and difcoveries, or that have been confirmed by them. Such efpecially is the fact recorded by Protagorides of Cyzicum, quoted by Athenæus, who relates, that in the time of king Antiochus, it was ufual, as a luxury, to cool water by evaporation: and alfo the phenomenon noticed by the ancients, that water ufually froze the more readily for having been boiled.

The era of the revival, or perhaps we may juftly fay, of the commencement of phyfical difcoveries, was the 13th century; to which period we may refer the famous Roger Bacon; Hugo Bertius, who is faid to have defcribed the polarity of the magnetic needle, though fome fuppofe that the defcription of it was contained in verfes attributed to Guyot, a French poet, who lived about the year 1180; Gioja of Amalfi, who firft employed the compafs in navigation about the year 1260; Peter Adfiger, who mentions the declination of the needle from the true meridian in a manufcript bearing date 1269 (fee MAGNET); and the poet Dante, who, about the clofe of this century, diftinguifhed himfelf by his philofophical, as well as literary works, and who has given an effay on the nature of the elements. Amongft the philofophers of later date, to whom the fciences, comprehended under the head of Phyfics, are indebted, we might mention Dr. Gilbert of Colchefter, who flourifhed about the clofe of the 16th century, and to whofe writings on magnetifm and electricity we have referred under thofe articles. The change or variation of the declination of the needle, the difcovery of which has been commonly afcribed to Gellibrand, in 1625, muft have been inferred, fays Dr. Young, from Gunter's obfervations, made in 1622, if not from thofe of Mair, or of fome other perfon as early as 1612; for at this time the declination was confiderably lefs than Burrows had found it in 1580. In the beginning of the 17th century lord Bacon acquired, by his laudable efforts to explode the incorrect modes of reafoning which had prevailed in the fchools, the juft character of a reformer of philofophy: but his difcoveries were neither numerous nor ftriking. In 1620, he propofed an opinion, with refpect to heat, which appears to have been then new, inferring from a variety of obfervations, detailed in his "Novum Organum," that it confifted in "an expanfive motion, confined and reflected within a body, fo as to become alternate and tremulous: having alfo a certain tendency to afcend." A fimilar opinion, refpecting the vibrating nature of heat, was fuggefted, about the fame time, by David Gorlæus, and it was afterwards adopted by Defcartes, as a part of his hypothefis, concerning the conftitution of matter. (See CARTESIANISM.) In the year 1620 Cornelius Drebel invented a method of meafuring the degrees of heat by a thermometer, which, in its firft and imperfect ftate, was a very important inftrument; but it was much improved at the clofe of the century by Dr. Hooke's difcovery of the permanency of the temperature of boiling water; which afforded a correct and convenient limit to the fcale on one fide, as the melting of fnow ferved for fixing a fimilar point on the other. The true courfe of the circulation of the blood was difcovered by Dr. Harvey in 1628. (See CIRCULATION *of the Blood.*) In the middle of the 17th century the barometer was invented by Torricelli; the variation of the atmofpheric preffure was difcovered by Defcartes; and Pafcal made feveral experiments which led to the method of determining heights by barometrical obfervations. (See AIR, ATMOSPHERE, and BAROMETER.) We pafs over the obfervations of Gefner and Aldrovandus with refpect to the animal kingdom, and thofe a century later of the Bauhins, on the vegetable kingdom: and alfo of Ray and Willughby, Tournefort and Reaumur; and proceed to mention, that the latter half of the 17th century was rendered a very interefting period in the hiftory of natural knowledge by the eſtabliſhment of the philoſophical ſocieties of Europe; ſuch were the Royal Society of London, in which Boyle, Hooke, Halley, and Newton, diſtinguiſhed themſelves; and the Academy of Sciences at Paris; and alſo, though of leſs extent and ſhorter duration, the Florentine Academy del Cimento. (See ACADEMY and SOCIETY.) In the middle of the 18th century the ſcience of electricity was diligently cultivated by Stephen Gray, Haukſbee, Dufay, Winkler, Nollet, Muſchenbroek, Franklin, Wilſon, Canton, Henly, &c. &c. (See ELECTRICITY.) The celebrated Linnæus, in his ſyſtem of botany and zoology, has contributed in a very eminent degree towards bringing near to perfection the logic and phraſeology of natural hiſtory; nor has he wholly neglected the philoſophy of the ſcience. His ſucceſſors have acquired diſtinguiſhed merit in theſe departments of ſcience; but it would be almoſt endleſs to recount the names even of thoſe who have moſt excelled: among whom we may reckon Buffon, Spallanzani, Daubenton, Geoffroy, Pennant, the Juſſieus, Lacepede, Haüy, Bergmann, Kirwan, Werner, Shaw, Smith, &c. &c.

The abſorption of heat, during the converſion of ice into water, appears to have been ſeparately obſerved by De Luc, Black, and Wilke, about the year 1755. On this experiment Dr. Black principally founded his doctrine of latent heat, ſuppoſed to be retained in chemical combination by the particles of fluids. Dr. Irvine and Dr. Crawford explained the circumſtances ſomewhat differently, by the theory of a change of capacity for heat only. Bergmann, Lavoiſier, Seguin, Kirwan, Laplace, and many other philoſophers, have illuſtrated, by experiments and calculations, the various opinions which have been entertained on this ſubject; and few chemiſts, from the times of Boerhaave, Stahl, and Scheele, to thoſe of Prieſtley and other later authors, have left the properties of heat wholly unnoticed. For an account of the elegant hypotheſis of Aepinus reſpecting magnetiſm and electricity, founded in a great meaſure on the theory of Franklin, and advanced in 1759, we refer to MAGNETISM and ELECTRICITY. The electrophorus of Wilke, and the condenſer of Volta, are among the earlieſt fruits of the cultivation of a rational ſyſtem of electricity. (See ELECTROPHORUS and CONDENSER.) Mr. Cavendiſh's inveſtigation of the properties of the torpedo may ſerve as a model of accuracy and preciſion in the conduct of experimental reſearches. (See TORPEDO.) The ſpeculations of Boſcovich reſpecting the fundamental properties of matter, and the general laws of the mutual action of bodies on each other, (ſee MATTER,) have been conſidered by ſome candid judges as deſerving the higheſt commendation: they remain, however, ſays Dr. Young, almoſt in all caſes ſpeculations only; and ſome of the moſt intricate of them, being calculated for the explanation of ſome facts which have perhaps been much miſunderſtood, muſt conſequently be both inaccurate and ſuperfluous. The attention of ſeveral experienced philoſophers, now living, has been devoted, with much perſeverance, to the difficult ſubject of hygrometry: ſuch are De Luc, Sauſſure, Pictet, and Dalton. For ſome years paſt, the diſcoveries of Galvani, Volta, and others, have commanded particular attention; for an account of which, ſee *Galvanic* BATTERY, GALVANISM, and VOLTAISM. Count Rumford has not only contributed to the extenſion of phyſical ſcience by his own experiments and obſervations relating to light and heat, and alſo other ſubjects, but by his eſtabliſhment of a prize medal to be given at the interval of every three years by the Royal Society to the author of the moſt valuable diſcovery concerning heat or light. Profeſſor Leſlie entitled himſelf to one of theſe medals by his intereſting diſcovery of the different properties poſſeſſed by ſurfaces of different kinds, with regard to the emiſſion or reception of radiant heat. Perhaps, however, ſays Dr. Young, none of the modern improvements in ſpeculative ſcience deſerve a higher rank than Dr. Herſchel's diſcovery of the ſeparation of heat from light by refraction. M. Prévoſt has made ſome juſt remarks on the experiments of other philoſophers reſpecting heat; and his own theory of radiant heat, and his original inveſtigations on the effects of the ſolar heat on the earth, have tended materially to illuſtrate the ſubject of his reſearches. The general laws of the aſcent and deſcent of fluids in capillary tubes, and between plates of different kinds, had been long ago eſtabliſhed by the experiments of Haukſbee, Jurin, and Muſchenbroek (ſee ASCENT of *Fluids*, and CAPILLARY *Tubes*): many other circumſtances, depending on the ſame principles, had been examined by Taylor, Achard, and Guyton; and ſome advances towards a theory of the forms aſſumed by the ſurfaces of liquids, had been made by Clairaut, Segner, and Monge. Dr. Young, in an eſſay on the coheſion of fluids, read before the Royal Society in the year 1804, has reduced all effects of this nature to the joint operation of a coheſive and repulſive force, which balance each other; aſſuming only that the repulſion is more augmented by the approach of the particles to each other than the coheſion: and he has thus diſcovered a perfect correſpondence between many facts, which had not been ſuppoſed to have the ſlighteſt connection with each other. About a year after the publication of this paper, M. Laplace read to the National Inſtitute at Paris a memoir on capillary tubes, in which, as far as he has purſued the ſubject, he has preciſely confirmed the moſt obvious of Dr. Young's concluſions, although his mode of calculation appears, in our author's judgment, to be by no means unexceptionable, as it does not include the conſideration of the effects of repulſion.

Dr. Young, of whoſe hiſtory of Terreſtrial Phyſics in the firſt volume of his "Courſe of Lectures on Natural Philoſophy and the Mechanical Arts," we have availed ourſelves in the compilation of this article, cloſes his hiſtory with the following obſervations. "When we reflect on the ſtate of the ſciences in general, at the beginning of the 17th century, and compare it with the progreſs which has been ſince made in all of them, we ſhall be convinced that the laſt two hundred years have done much more for the promotion of knowledge, than the two thouſand that preceded them: and we ſhall be ſtill more encouraged by the conſideration, that perhaps the greater part of theſe acquiſitions has been made within fifty or ſixty years only. We have therefore the ſatisfaction of viewing the knowledge of nature not only in a ſtate of advancement, but even advancing with increaſing rapidity; and the univerſal diffuſion of a taſte for ſcience appears to promiſe, that, as the number of its cultivators increaſes, new facts will be continually diſcovered, and thoſe, which are already known, will be better underſtood, and more beneficially applied. The Royal Inſtitution, with other ſocieties of a ſimilar nature, will have the merit of aſſiſting in the diſſemination of knowledge, and in the cultivation of a taſte for its purſuit; and the advantages ariſing from the general introduction of philoſophical ſtudies, and from the adoption of the practical improvements depending on them, will amply repay the labours of thoſe, who have been active in the eſtabliſhment and ſupport of aſſociations ſo truly laudable."

Chronology of Phyſical Authors.



Phyſics may be divided, with regard to the manner in which it has been treated, and the perſons by whom, into

Physics, *Symbolical*, or ſuch as was couched in ſymbols: ſuch was that of the old Egyptians, Pythagoreans, and Platoniſts, who delivered the properties of natural bodies under arithmetical and geometrical characters, and hieroglyphics.

Peripatetical, or that of the Ariſtotelians, who explained the nature of things by matter, form, and privation, elementary and occult qualities, ſympathies, antipathies, attractions, &c. See Aristotelian and Peripatetics.

Experimental, which inquires into the reaſons and natures of things from experiments, ſuch as thoſe in chemiſtry, hydroſtatics, pneumatics, optics, &c. See Experimental *Philoſophy*.

And finally, *mechanical*, or *corpuſcular*, which explains the appearances of nature from the matter, motion, ſtructure, and figure of bodies, and their parts: all according to the ſettled laws of nature and mechanics. See Mechanical and Corpuscular *Philoſophy*.

PHYSIOGNOMICS, a term uſed by ſome phyſicians and naturaliſts, for ſuch ſigns as are taken from the countenance to judge of the ſtate, diſpoſition, &c. of the body and mind.

PHYSIOGNOMY, Φυσιογνωμια, formed from φυσις, *nature*, and γινωσκω, *I know*, the art of knowing the humour, tem-

temperament, or disposition of a person, from observation of the lines of his face, and the characters of its members or features; or of designating the powers and dispositions of the mind by a peculiar combination of the features.

Baptista Porta and Robert Fludd, to whom we may add in later times, Gall, Camper, Lavater, and Blumenbach, are the best modern authors on physiognomy. The ancient ones are the sophists Adamantius and Aristotle: the physiognomy of which last we have translated into Latin by de Lacuna.

With respect to physiognomy, this at least may be said, that of all the fanciful arts of the ancients, disused for a considerable time, but lately revived among the moderns, there is none has so much foundation in nature as this.

There is an apparent correspondence between the face and the mind: the features and lineaments of the one are directed by the motions and affections of the other; there is even a peculiar arrangement of the members of the face, and a peculiar disposition of the countenance, corresponding to each particular affection of the mind.

In effect, the language of the face, physiognomy, as the zealous advocates of this art pretend, is as copious, nay, perhaps, as distinct and intelligible, as that of the tongue, speech. In other words, it is plain to the most inattentive observer, that each individual of the human race possesses a set of distinctive marks in the form of the head, and the outlines of the countenance: in proof of which we refer to the articles CRANIOLOGY, CRANIUM, and MAN. It is also well known and universally allowed, that these marks insensibly lead us to form conclusions as to the nature and inclinations of persons at the first sight, or on the slightest acquaintance with them; which notions are sometimes just, but often erroneous.

The foundation of physiognomy, as some have stated it, is this: the different objects that present themselves to the senses, nay, the different ideas that arise in the mind, do each make some impression on the spirits; and each an impression correspondent or adequate to its cause: therefore each makes a different impression.

If it be asked, how such an impression should be effected, it is easy to answer, that it follows from the economy of the Creator, who has fixed such a relation between the several parts of the creation, to the end that we may be apprized of the approach or recess of things useful or hurtful to us.

The animal spirits, say the Cartesians, moved in the organ by an object, continue their motion to the brain: whence that motion is propagated to this or that particular part of the body, as is most suitable to the design of nature; having first made a proper alteration in the face, by means of its nerves, especially the pathetici, and oculorum motorii.

The face, here, does the office of a dial-plate; and the wheels and springs, withinside the machine, actuating its muscles, shew what is next to be expected from the striking part.

Now if, by repeated acts, or the frequent entertaining of a favourite passion, or vice, which natural temperament was hurried, or custom dragged one to, the face is often put in that posture which attends such acts; the animal spirits will make such patent passages through the nerves (in which the essence of an habit consists), that the face is sometimes unalterably set in that posture (as the Indian religious are by a long continued sitting in strange postures in their pagods); or, at least, it falls, insensibly and mechanically, into that posture, unless some present object distort it therefrom, or some dissimulation hide it; and this reasoning, it has been said, is confirmed by observation; which, y being a little more accurate and minute, would serve to distinguish not only habits and tempers, but even professions. After all, this is a kind of science which must be very precarious and delusive. (See LAVATER.) It should therefore be exercised with great judgment and discretion; otherwise we may deduce from it conclusions that are equally unfounded and injurious. To the observations on the theory of this science already introduced under the articles to which we have above referred, we shall here subjoin an account of the system of Lavater, which not long ago excited the public curiosity, though it is now almost forgotten.

Lavater asserts, that "each creature is indispensable in the vast compass of creation; but each individual," he adds, "is not alike informed of the truth of this fact, as man only is conscious that his own place cannot be supplied by another." The idea thus conceived, he thinks one of the best consequences of physiognomy, and he exults, that the most deformed and wicked persons are still superior to the most perfect and beautiful animal, because they always have it in their power to amend, and in some degree to restore themselves to the place assigned them in creation; and however their features may be distorted by the indulgence of their passions, still the image of the Creator remains, from which sin only is to be expelled, to render the likeness nearer perfection. In pointing out the distinguishing traits that discriminate the natives of different regions, Lavater observes, that the placing of several persons together, selected from nations remotely situated from each other, gives at one glance their surprising varieties of visage; and yet he acknowledges that to point out those variations is a task of considerable difficulty, and his assertion, that this may be done with more facility from an individual than the mass of population, seems extremely probable. The French, he thinks, do not possess equally commanding traits with the English, nor are they so minute as those of the Germans, and it is to the peculiarities of their teeth, and manner of laughing, that he attributed his power of deciding on their origin. The Italians he appropriated by the form of their noses, their diminutive eyes, and projecting chins. The eye-brows and foreheads are the criterion by which to judge of the natives of England. The Dutch possess a particular rotundity of the head, and have weak, thin hair: the Germans, numerous angles and wrinkles about the eyes and in the cheeks; and the Russians are remarkable for black and light coloured hair, and flat noses.

It must be extremely grateful to the natives of England to reflect, that Lavater considers them, in the aggregate, the most favoured upon the earth with respect to personal beauty; he says, they have the shortest and best arched foreheads, and that only upwards, and towards the eye-brows, sometimes gradually declining, and in other cases are rectilinear, with full, medullary noses, frequently round, but very seldom pointed, and lips equally large, well defined, curved, and beautiful, with the addition of full round chins. Still greater perfections are attributed to the eyes of Englishmen, which are said to possess the expression of manly steadiness, generosity, liberality, and frankness, to which the eye-brows greatly contribute. With complexions infinitely fairer than those of the Germans, they have the advantage of escaping the numerous wrinkles found in the faces of the latter, and their general *contour* is noble and commanding.

Judging from the ladies he had seen of our country, and from numerous portraits of others, Lavater was led to say, they appeared to him wholly composed of nerve and marrow, tall and slender in their forms, gentle, and as distant from coarseness and harshness as earth from heaven. His own countrymen he found to have many characteristic varieties:

varieties: thofe of Zurich are generally meagre, and of the middle fize, and either corpulent or very thin.

To purfue this fubject fomething further, it will be found, that the people of Lapland, and parts of Tartary, are of very diminutive ftature, and of extremely favage countenances, formed by flat faces, broad nofes, high cheek-bones, large mouths, thick lips, peaked chins, and their eyes are of a yellow brown, almoft black, with the lids retiring towards the temples; nor are the females of this difagreeable race more favoured by nature; and each fex is diftinguifhed by the groffeft manners, and minds ftupid beyond credibility; but of all the varieties of the human fpecies, the inhabitants of the coaft of New Holland feem the moft debafed and miferable; thofe are tall and flender, and to add to the deformity of thick lips, large nofes, and wide mouths, they are taught from their infancy to keep their eyes nearly clofed, to avoid the infects which fwarm around them.

Turning to the more favourable fide of this picture of national phyfiognomy, we fhall find the people of Cachemire, the Georgians, the Circaffians, and Mingrelians, erect, noble, and formed for admiration, particularly the females, whofe charms of face and perfon are proverbial.

There are too many local and phyfical caufes for this difference in the external appearance of the inhabitants of the different parts of the world, for enumeration and explanation in fo confined a fpace as that to which we are limited. Profeffor Kant, of Konigfberg, in an effay on this fubject, divides the human race into four principal claffes, into which the intermediate gradations may readily be refolved: thofe are the Whites, the Negroes, the Huns, (Monguls or Calmucs,) and the Hindoos, or people of Hindooftan. Circumftances purely external may be the accidental, but cannot be the original caufes of what is affimilated or inherited: as well could chance produce a body completely organized. " Man," fays the profeffor, " was undoubtedly intended to be the inhabitant of all climates and all foils. Hence the feeds of many internal propenfities muft be latent in him, which fhall remain inactive, or be put in motion according to his fituation on the earth: fo that in progreffive generation, he fhall appear as if born for that particular foil in which he feems planted."

In the opinion of this gentleman, the air and the fun are the two caufes which moft powerfully influence the operations of propagation, and give a lafting developement of germ and propenfities, or in other words, the above powers may be the origin of a new race.

Food may produce fome flight variations; thefe, however, muft foon difappear after emigration, and it is evident, that whatever affects the propagating powers, does not act upon the fupport of life; but upon the original principle, the very fource of animal conformation and motion. It has been obferved, that man degenerates in ftature and faculties the nearer he is fituated to the frigid zone: this feems a neceffary confequence of that fituation, for this obvious reafon; were men of the common ftature in thofe regions of extreme cold, the impelling power of the heart muft be increafed, to force the blood through the extremities, which would otherwife chill, and become totally ufelefs; but as the Creator did not think it ufeful to adopt this mode of preferving the limbs, they have been fhortened, for the purpofe of confining the circulating fluid to the trunk, where the natural heat accumulating, the whole body has a greater proportion of that comfortable fenfation than ftrangers feel when vifiting thofe northern countries.

The propenfity to flatnefs, obfervable in the prominent parts of the countenance of the perfons under confideration, expofed to the effects of cold, is accounted for by that very circumftance; and it appears probable, that their high cheek-bones, and fmall, imperfect eyes are fo contrived, to preferve the latter from the piercing effects of the wind, and the offenfive brilliancy of the almoft eternal fnows. The abbé Winkelman attributes the enormous and difgufting lips of the Negroes to the heat of the climate they inhabit; others account for the blacknefs of their fkin by fuppofing " the furplus of the ferruginous, or iron particles, which have lately been difcovered to exift in the blood of man, and which, by the evaporation of the phofphoric acidities, of which all Negroes fmell fo ftrong, being caft upon the retiform membrane, occafions the blacknefs which appears through the cuticle, and this ftrong retention of the ferruginous particles feems to be neceffary, in order to prevent the general relaxation of the parts."

In pointing out the diftinguifhing traits that difcriminate the natives of different regions, Lavater obferves, that a perfon deeply enamoured of another, and thinking intenfely on the form and pofition of their features, might affume a refemblance of the admired object, though miles of fpace intervened between them; and purfuing his mental dream, he adds, that it is equally probable an individual meditating revenge in fecret, may compofe his countenance into a likenefs of him who was to be its victim. The incorrectnefs of the latter fancy may be expofed by merely obferving that the perfon under the influence of the paffion of revenge, muft bear in his countenance the lines expreffive of that reftlefs affection; now as the object intended to be injured is unconfcious of the fecret machinations againft him, he may at the inftant be engaged in fome benevolent purfuit, or may feel fome internal joy which moulds his features into an expreffion directly oppofite to that of his adverfary, who may have generally feen him thus; for revenge is often aimed by the wicked at the beft of men: confequently, the countenance of a fiend grinning with malice cannot at the fame time beam with a complacency arifing from a fet of features entirely unruffled.

Before we enter upon a defcription of the marks which, according to Lavater, point out the character of the poffeffor, it may be proper to give one or two inftances of the fallacy, and of the truth, of the conclufions drawn from them, in order that our readers may form their own conclufions, as to the folly or propriety of entertaining a propenfity to form a judgment of mankind from the fhapes of their nofes, eyes, foreheads, and chins.

M. Sturtz declared to Lavater, that he " once happened to fee a criminal condemned to the wheel, who, with fatanic wickednefs, had murdered his benefactor, and who yet had the benevolent and open countenance of an angel of Guido. It is not impoffible, adds this gentleman, to difcover the head of a Regulus among guilty criminals, or of a veftal in the houfe of correction." Lavater admits this affertion in its fulleft extent, but his reafoning to reconcile it to his fyftem is by no means conclufive.

When we hear of any atrocious act, the natural abhorrence of vice and cruelty implanted in us, leads the imagination to form a portrait of the perpetrator, fuited to the deformity of the mind capable of committing it; without reflecting, that had fuch an index exifted in the countenance of the abhorred object, it is moft probable, his murderous and horrible exterior would have placed mankind fo far on their guard as to detect his intentions. Upon viewing the culprit, we are perhaps furprifed to find that there is nothing particularly indicative of cruelty in the outlines of his face, and we induftrioufly endeavour to force each into the immediate form of our preconceived portrait; this occafions us to read lurking villainy in his eyes, and converts the wrinkles

kles of diſeaſe, or approaching age, into the frown of a dæmon; and we depart exclaiming againſt the ſtriking contour of the miſerable wretch, when, perhaps, many of our friends, and even relatives, would ſuffer by a compariſon, and yet had led uniformly innocent lives. On the other hand it muſt be admitted, that vice generally ſtamps her votaries with marks, which may be known at a glance, but this admiſſion applies only to the confirmed enemies of virtue, thoſe whoſe habits of living are ſo uniformly vicious, that very little propriety occurs in their conduct.

The following anecdote, related by Lavater, may ſerve as a partial illuſtration of the aſſertion, that the features are affected by the turn of the mind, or, perhaps, more correctly ſpeaking, the muſcles of the face. An innocent, amiable, and virtuous young lady, of high birth, who had beed educated in the retirement of the country, happened one evening to paſs a mirror, immediately after having attended evening prayers, and with a candle in her hand was depoſiting a bible on a table, when ſhe obſerved her image reflected in the glaſs: affected with a ſenſe of humility, and of extreme modeſty, ſhe averted her eyes and retired. A ſucceeding winter was paſſed in the amuſements and diſſipation of a city, where this lady had the misfortune to forget all her previouſly devout purſuits: but returning to the country, ſhe once more paſſed the glaſs and the bible, and ſaw her features reflected, now deprived of thoſe faſcinating graces which belong alone to the ſerene and happy ſtate of mind ſhe had loſt. Alarmed at the change, ſhe fled from the ſpot, and retiring to a ſofa, ejaculated ſentences of penitence, and formed reſolutions of future amendment.

Lavater begins his remarks on the human face with the forehead. According to this obſerver, the general form, proportion, the arch obliquity, and poſition of the ſkull of the forehead, denote the degree of thought, the ſenſibility, the mental vigour, and the propenſities of man; and at the ſame time the ſkin of this part of the head explains, by its hue, tenſion, or wrinkles, the ſtate of the mind at the moment of obſervation, and the paſſions which influence it, the bones affording the internal quantity, and the covering the application of power: however the latter may be affected, it is well known that the bones muſt remain unaltered, and yet they regulate the wrinkles by their variation of component form. Wrinkles are produced by a certain degree of flatneſs; others ariſe from arching, and theſe conſidered ſeparately will give the form of the arch, and *vice verſâ*. Some foreheads are furniſhed with wrinkles that are confined to horizontal, perpendicular, curved, and others confuſed and mixed lines; thoſe leaſt perplexed when in action are uſually obſerved in foreheads without angles.

Lavater appears to have been the firſt who attended to the peculiar turns of the poſition and outline of the forehead, which he conſidered the moſt important part preſented for the ſtudy of the phyſiognomiſt. This he divides into three claſſes, and thoſe he termed the perpendicular, the projecting, and the retreating, each poſſeſſing a number of variations: the principal, however, are rectilinear, "half round, half rectilinear, flowing into each other; half round, half rectilinear, interrupted; curve-lined, ſimple; the curve lined double and triple."

A long forehead denotes much capacity of comprehenſion, and leſs activity; a compreſſed, ſhort, and firm forehead, more compreſſion, ſtability, and little volatility; ſeverity and pertinacity belong to the rectilinear; and the more curved than angular portends flexibility and tenderneſs of character; deficiency of underſtanding is diſcoverable in thoſe whoſe foreheads are perpendicular from the hair to the eye-brows; but the perfectly perpendicular, gently arched at the top, ſignifies that the poſſeſſor thinks coolly and profoundly. The projecting forehead indicates ſtupidity and mental weakneſs; the retreating, exactly the reverſe; the circular, and prominent above, with ſtraight lines below, and nearly perpendicular, ſhews ſenſibility, ardour, and good underſtanding; the rectilinear oblique forehead has the ſame properties; arched foreheads are conſidered as feminine; an union of curved and ſtraight lines, happily diſpoſed, with a ſimilar poſition of the forehead, gives the character of conſummate wiſdom. "Right lines, conſidered as ſuch, and curves, conſidered as ſuch, are relaxed, as power and weakneſs, obſtinacy and flexibility, underſtanding and ſenſation." When the bones ſurrounding the eye project, and are ſharp, the perſon thus formed poſſeſſes a powerful ſtimulus to exerciſe a ſtrong mental energy, which is productive of excellent and well digeſted plans, and yet this doth not ſeem a peculiar mark of wiſdom, as many wiſe men have been known without it: thoſe thus circumſtanced have more firmneſs, when the forehead reſts perpendicularly upon horizontal eye-brows, and is conſiderably rounded towards the temples. Perpendicular foreheads, which, however, project ſo as not to reſt on the noſe, and which are ſhort, ſmall, ſhine, and are full of wrinkles, give undoubted indications of a weakneſs of the thinking faculties; perſeverance and oppreſſive violent activity, united with vigour and harſhneſs, belong to the forehead compoſed of various confuſed protuberances; and on the other hand, when the profile of this part of the head affords two well proportioned arches, the loweſt projecting, it is a certain ſign of a good temperament and a ſound underſtanding. All great and excellent men have been found to have their eyebones firmly arched, and well defined; and circumſpection, followed by ſtability, attends ſquare foreheads, with ſpacious temples, and eye-bones of the above deſcription; when perpendicular natural wrinkles appear, they expreſs power of mind and application; but horizontal, interrupted in the middle, or broken at the extremities, betray, in general, negligence, if not want of ability.

Deep indenting in the bones of the forehead ſituated between the eye-brows, and extending in a perpendicular direction, mark the happy few who poſſeſs generous and noble minds, connected with excellence of underſtanding; beſides, a blue vena frontalis, in the form of a Y, ſituated in an arched ſmooth forehead, is an indication of ſimilar advantages. Lavater having given the above hints, deſcribes the following characteriſtics, which he aſſerts, give "the indubitable ſigns of an excellent, a perfectly beautiful and ſignificant, intelligent, and noble forehead." Such muſt be one-third of the face in length, or that of the noſe, and from the noſe to the chin; the upper part muſt be oval, in the manner of the great men of England, or nearly ſquare; the ſkin muſt be ſmooth, and wrinkled only when the mind is rouſed to juſt indignation, or deeply immerſed in thought, and during the paroxyſm of pain; the upper part muſt recede, and the lower project; the eye-bones muſt be horizontal, and preſent a perfect curve upon being obſerved from above; an interſecting cavity ſhould divide the forehead into four diſtinct parts, but with that ſlight effect as to be only viſible with a clear deſcending light; and all the outlines ſhould be compoſed of ſuch, that if the ſection of one-third only is obſerved, it would be difficult to decide whether they were circular or ſtraight; to conclude this portrait of a tranſcendant forehead, the ſkin muſt be more tranſparent, and of a finer tint than the remainder of the face. Should an infant, a relative, or a friend, who poſſeſſes a forehead reſembling the above deſcription, ſeriouſly err, the good enthuſiaſt intreats, that the corrector may not deſpair of ſucceſs;

cefs, as in all human probability the latent feeds of virtue may be roufed into growth by perfeverance, and finally produce the defired fruit.

The eyes of mankind are compofed of various fhades of colour, the moft common of which are grey mixed with white, grey tinged with blue, and fhades of green, orange, and yellow. According to Buffon, the orange and blue are moft predominant, and thofe colours often meet in the fame eye; thofe generally fuppofed to be black are not really fo, and may be found, on attentive examination, and with a proper difpofition of the light, to confift of yellow, a deep orange, or brown, which being violently oppofed to the clear white of the ball, affumes a darknefs miftaken for black. The fame naturalift obferves, that fhades of yellow, orange, blue and grey, are vifible in the fame eye; and when blue, even of the lighteft tint, appears, it is invariably the predominant colour, and may be found in rays difperfed throughout the iris: the orange is differently difpofed, at a trifling diftance from the pupil, is in flakes, and round; but the blue fo far overpowers it, that the eye affumes the appearance of being wholly of that colour. The fire and vivacity emitted by the eye cannot be fo powerful in thofe of the lighter tints; it is therefore in the dark ones alone that we look for the emotions of the foul; quiet and mildnefs, and a certain degree of archnefs, are the characteriftics of the blue. Some eyes are remarkable for the abfence of colour; the iris is faintly fhaded with blue or grey, and the tints of orange are fo light, that they are hardly obfervable: in eyes thus conftituted, the black of the pupil appears too confpicuous, and it may be faid, that portion is alone vifible at a little diftance, which circumftance gives the perfon a ghaftly and fpiritlefs appearance.

There are eyes whofe iris may be faid to be almoft green; but thefe are very uncommon. It would require the pen of an infpired writer to defcribe the aftonifhing variety of expreffion of which the eyes are capable: being fituated near the fuppofed feat of the foul, every fenfation of that invifible fpirit appears to rufh in full vigour from thofe intelligent organs: all the paffions may be feen in them; we fhrink from their indications of anger, we find pleafure with all her train of joys dancing in them, we feel their force in love, and melt into tears upon obferving them fuffufed with the moifture of grief; in fhort, their language is far more powerful than that of the tongue. The tranfitions are fo rapid in the expreffion of the eyes, that it requires very clofe and attentive examination to catch and defcribe the emotions of the mind vifible in them; admitting this fact, it will appear that the phyfiognomift is liable to numerous and egregious errors in drawing his conclufion of propenfities from them. Paracelfus, a man of ftrong genius, and, like Lavater, mifguided in many inftances by enthufiafm, and a kind of fuperftition allied to the ftudy of this art or fcience, pronounced that thofe eyes generally termed black frequently denoted health, firmnefs, courage, and honour; but the grey, deceit and inftability. Thus far probability at leaft accompanies his remarks. It is, however, impoffible to fubfcribe to his affertion, that fhort-fighted perfons are deceitful and crafty, or that thofe who fquint have fimilar propenfities to evil, as it is evident both the peculiarities alluded to are the confequences of injury, and are never found in people whofe organs of vifion are perfect: indeed many inftances might be cited of the actual and known caufe of fquinting and near fight, which frequently occur in adults from extreme anxiety and difeafe.

Small eyes fituated deep in the fockets are faid, by Paracelfus, to indicate active wickednefs, with a mind calculated to oppofe with vigour, and fuffer with perfeverance; and their oppofites, or very large prominent eyes, he conceived, explained the avaricious, covetous, propenfities of their poffeffor; thofe in conftant motion denote fear and care; winking is the mark of forefight, of an amorous difpofition, and quicknefs in projecting; and the eye fearful of looking directly forward, decides upon innate modefty.

Lavater thought blue eyes, in general, fignified effeminacy and weaknefs, and yet he acknowledged that many eminent men have had blue eyes; ftill he was convinced that ftrength and manhood more particularly belong to the brown: in oppofition to this opinion, the Chinefe, who are known to be an imbecile people, rarely have blue eyes; thefe contradictions, it muft be confeffed, weaken the reliance we are inclined to place on appearances during the quiefcent ftate of the eyes, and the indications of their colour. Men intemperate in anger, and eafily irritated, may be found with eyes of all the ufual colours; when they incline to green, ardour, fpirit, and courage, are conftant attendants. People of a phlegmatic habit, but who may be roufed to activity, have clear blue eyes, which never belong to thofe inclined to melancholy, and they rarely belong to the choleric. Benevolence, tendernefs, timidity, and weaknefs, are exhibited by the perfectly femi-circular arch formed by the under part of the upper eye-lid; perfons of acute and folid underftandings have a generous open eye, compofing a long and acute angle with the nofe; and when the eye-lid forms a horizontal line over the pupil, it is a ftrong indication that he who poffeffes it is fubtle, able, and penetrating. Widely opening lids, fhewing the white of the ball under the other colours, may be obferved in the phlegmatic and timid, as well as in the courageous and rafh; but upon comparing thefe marks in the different characters juft mentioned, a very perceptible difference is difcovered in the characteriftics of the eyes; the latter are lefs oblique, better fhaped, and more firm.

The eye-brows are effential in the expreffion of the eyes; in anger they are brought down and contracted; in all pleafant fenfations, and in aftonifhment, they affume a fine arch; in youth they are naturally and regularly arched; the horizontal and rectilinear eye-brows belong to the mafculine bias of the foul; and the above defignations combined fhew ftrength of underftanding, united with feminine kindnefs; thofe that are deranged in their appearance, and the hairs growing in various directions, demonftrate a wild and perplexed ftate of mind; but if the hair is fine and foft, they fignify gentle ardour. The compreffed firm eye-brow, formed of parallel hairs, is a certain proof of profound wifdom, true perception, and a manly, firm habit of thought. There are eyebrows which meet acrofs the nofe; this circumftance gives the perfon an air of ferocious gloom, which is admired by the Arabs, but the ancients, verfed in phyfiognomy, conceived fuch to be the characteriftic of cunning; Lavater, on the contrary, obferves, that he had difcovered them on the moft worthy and open countenances, admitting at the fame time that they may denote a heart ill at eafe. Thofe who think profoundly, and thofe equally prudent and firm in their conduct, never have high and weak eye-brows, in fome meafure equally dividing the forehead; they rather betray debility and apathy, and though men of an oppofite character may be found with them, they invariably fignify a diminution of the powers of the mind. Thick angular eye-brows, interrupted in their lengths, fignify fpirit and activity; and when they approach the eyes clofely, the more firm, vigorous, and decided, is the character; the reverfe fhews a volatile and lefs enterprifing difpofition; when the extremes are remote from each other, the fenfations of the poffeffor are fudden and violent. White eye-brows are demonftrative of weaknefs, in the fame degree that the dark brown are of firmnefs.

The good Lavater confidered the nofe as the abutment, or buttrefs, of the forehead, the feat of the brain, without which the whole face would prefent a miferable appearance; indeed an ugly or difagreeable fet of features is never accompanied by a handfome nofe: but there are thoufands of fine and expreffive eyes where a perfectly formed nofe is wanting: he defcribes this portion of the face as requiring the following peculiarities: "Its length fhould equal the length of the forehead; at the top fhould be a gentle indenting; viewed in front, the back fhould be broad, and nearly parallel, yet above the centre fomething broader; the bottom, or end of the nofe, muft be neither hard nor flefhy, and its under outline muft be remarkably definite, well delineated, neither pointed nor very broad; the fides, feen in front, muft be well defined, and the defcending noftrils gently fhortened; viewed in profile, the bottom of the nofe fhould not have more than one-third of its length; the noftrils above muft be pointed below, round, and have in general a gentle curve, and be divided into equal parts by the profile of the upper lip; the fide, or arch of the nofe, muft be a kind of oval; above, it muft clofe well with the arch of the eye-bone, and near the eye muft be at leaft half an inch in breadth. Such a nofe is of more worth than a kingdom." Numbers of great and excellent men have flourifhed in all ages of the world, whofe nofes would fuffer effentially by a comparifon with Lavater's defcription of a nofe, more valuable to the poffeffor than extenfive empire: indeed, he is compelled to acknowledge this indifputable fact, and obferves that he has feen perfons endowed with purity of mind, noble in their conceptions, and capable of exertion, whofe nofes were fmall, and the arches of their profiles inverted; and yet true to his firft principles, he difcovered, or imagined he difcovered, their worth to confift chiefly in the elegant effufions of their imaginations, their learning, or fortitude in fuffering, and this is accompanied with a provifo that the remainder of their form muft be correctly organized.

Nofes arched near the forehead belong to thofe who poffefs the energy to command, are capable of ruling, acting, overcoming, and deftroying; others, rectilinear, are the medium between the extremes above noticed, and are appropriated by nature to perfons who act and fuffer with equal power and patience. Socrates, Laireffe, and Boerhaave, were great men, and had ill-fhaped nofes, and were diftinguifhed for meeknefs and gentlenefs. Were it poffible to attribute a general prevalence of difpofition to a general form of the nofe, individuals of every nation would be found to refemble the Tartars, who have flat indented nofes, the Negroes who have broad, and the Jews who have high arched nofes, in their propenfities, and it muft follow that whatever qualities the phyfiognomift may apply to thofe individuals, muft alfo belong to the whole people whofe nofes bear a refemblance to them; were this particular accurately examined into, it would tend, in a great meafure, to confirm the correctnefs or incorrectnefs of the fcience, as it has hitherto been practifed.

The admirers of this ftudy attribute great powers to the mouth, in expreffing the emotions of the mind; and Lavater expatiates on it with enthufiaftic fervour indeed: "Whoever," he exclaims, "internally feels the worth of this member, fo different from every other member, fo infeparable, fo not to be defined, fo fimple, yet fo various; whoever, I fay, knows and feels this worth, will fpeak and act with divine wifdom." He then proceeds to call it "the chief feat of wifdom and folly, power and debility, virtue and vice, beauty and deformity, of the human mind; the feat of all love, all hatred, all fincerity, all falfehood, all humility, all pride, all diffimulation, and all truth." Granting the benevolent paftor full affent to thefe obfervations on the mouth, it becomes the indifpenfible duty of all men to notice the phyfiognomy, or indications of that organ; in making thofe obfervations, it will be neceffary to examine the lips feparately, and to afcertain when they are clofed, during the moments of perfect tranquillity, whether that operation is performed without a forcible exertion of the mufcles, particularly the middle of the upper and under lips, the bottom of the middle line at each end; and finally, the extending of the middle line on both fides.

The character of the man is proclaimed in the lips, the more firm the latter the more fixed the former; the weak and irrefolute man has weak lips, with rapidity in their motion. The vicious, cringing, mean, and bad countenance is never formed with lips well defined, large, and juftly proportioned to the other parts of the face, and the line of which is equally ferpentine on each fide; fuch, though they may denote a tendency to fenfuality, belong exclufively to a character deferving of admiration in moft relations of life.

A mouth, the lips of which are fo thin as to prefent, at firft view, little more than a line, is faid to indicate apathy and quiet, but induftrious when roufed. When this defcription of mouth is raifed at the extremities, vanity or vain pretenfions, affectation, and probably deliberate malice, diftinguifh thofe fo formed. The oppofite of this kind of lips, fwelled into confiderable fize, is a mark of indolence and fenfuality. The "cut through, fharp drawn lip," as Lavater terms fome, has to contend with avarice and anxiety. Lips clofed accurately, without exertion, and handfome in their outline, belong to the exercife of difcretion and firmnefs. Lips with the latter advantage, and the upper projecting, is generally appropriated to the virtuous and benevolent, though there are, without doubt, numberlefs perfons of excellent character whofe under lips project, but in Lavater's opinion, the laft peculiarity implies a well-meaning man, whofe goodnefs confifts rather of cold fidelity than ardent friendfhip. The under lip, hollowed in the middle, denotes a fanciful character. Let the moment be remarked, when the conceit of the jocular man defcends to the lip, and it will be feen to be a litle hollow in the middle.

The mouth remaining naturally clofed, invariably fignifies fortitude and courage. When the latter quality is in operation, the mouth clofes infenfibly; the naturally open mouth makes a difpofition to complain; the clofed, on the contrary, defignates endurance. "Though phyfiognomifts," adds Lavater, "have as yet but little noticed, yet much might be faid concerning the lips improper, or the flefhy covering of the upper teeth, on which anatomifts have not, to my knowledge, yet beftowed any name, and which may be called the curtain, or pallium, extending from the beginning of the nofe to the red upper lip proper. If the upper lip improper be long, the proper is always fhort; if it be fhort and hollow, the proper will be large and curved: —another certain demonftration of the conformity of the human countenance. Hollow upper lips are much lefs common than flat and perpendicular; the character they denote is equally uncommon."

The ancients who ftudied the phyfiognomy of man, fuppofed that diminutive fhort teeth betrayed the weaknefs of thofe who poffeffed them; more modern obfervers contradict this fuppofition, and declare that men of uncommon ftrength have fuch, but they are rarely of that pure white fo neceffary

to

to preserve the general beauty of the countenance. Teeth of unusual length, and narrow, are signs of weakness and cowardice; those justly proportioned to each other, white and transparent, which appear immediately upon opening of the mouth, though not projecting, and entirely exposed to view, from the insertion in the gums to the opposite extremities, are seldom to be met with in the jaws of persons who possess unamiable propensities; when teeth of a different description are discovered belonging to amiable and worthy characters, enquiry will generally satisfy the physiognomist that his conclusions on this head were just, and that the blackness and derangement were occasioned by disease.

In one way the observer and admirer of this art cannot possibly be mistaken, for he that neglects his teeth, suffering them to decay through contempt of public opinion and indolence, may be safely pronounced an unhappy character, with many evil propensities.

The chin alone remains to be noticed in this slight survey of the human face, as connected with the internal operations of the soul or mind. The projecting chin is said to mark something decided, and the receding the reverse; and it has been asserted that the presence or absence of strength is frequently demonstrated by the form of this part of the countenance; it has also been remarked, that sudden indentings in the midst of the chin are peculiar to men of excellent cool understandings, unless attended by marks of a contrary tendency. When the chin is pointed, those so formed are supposed to be penetrating and cunning, though it seems there are people with pointed chins who are different at least in the latter particular; and here again the chin offers a certain criterion for the physiognomist, who may securely pronounce a large fat double chin an appendage of gluttony. "Flatness of chin speaks the cold and dry; smallness, fear; and roundness, with a dimple, benevolence."

"No one," says Lavater, "whose person is not well formed can become a good physiognomist. Those painters were the best whose persons were the handsomest. Reubens, Vandyke, and Raphael, possessing three gradations of beauty, possessed three gradations of the genius of painting. The physiognomists of the greatest symmetry are the best. As the most virtuous can best determine on virtue, so can the most handsome countenances on the goodness, beauty, and noble traits of the human countenance, and consequently on its defects and ignoble properties. The scarcity of human beauty is the reason why physiognomy is so much desired, and finds so many opponents. No person, therefore, ought to enter the sanctuary of physiognomy, who has a debased mind, an ill-formed forehead, a blinking eye, or a distorted mouth. "The light of the body is the eye; if, therefore, thine eye be single, thy whole body shall be full of light! but if thine eye be evil, thy whole body shall be full of darkness: if therefore the light that is in thee be darkness, how great is that darkness?"

PHYSIOLOGI, in *Botany*, those authors whose writings tend to set that study in its clearest light, by explicating and enumerating the various dispositions of the male and female parts in the flowers of plants.

PHYSIOLOGY, Φυσιολογια, formed of φυσις, *nature*, and λογος, *discourse*, or *reason*, the doctrine of nature, or natural bodies; called also *physics*, and *natural philosophy*.

Physiology properly denotes only an internal reasoning, or discoursing, which stops or terminates in the speculation, or abstract contemplation of its object, *viz.* natural appearances, their causes, &c. and does not direct or prescribe rules for the making of natural things, *e. gr.* stones, plants, &c.

In which view, chemistry does not properly belong to physiology, but is a kind of counter part thereto, as in many cases, imitating nature, rather than considering and explaining her.

Physiology, according to its etymological import, signifies a discourse on nature; but it is now usually employed, in a more limited sense, to denote the science which treats of the powers that actuate the component parts of living animal bodies, and of the functions which those bodies execute. It presupposes therefore a knowledge of the structure of the body, which is the object of anatomy; the latter is conversant with the dead, the former with the living body; the one may be called the science of organisation, the other the science of life.

The principal source of our physiological knowledge of the human body, is an observation of its actions in all the various states comprehended under the general terms of health and disease. The results of the latter are very instructive: comparison of the phenomena during life with the state of parts after death, shews us the uses of many organs, which cannot be submitted to direct observation in the living state. But the information derived, even from the most attentive survey of the living human being in health and disease, is still very imperfect: it leaves many interesting subjects entirely unexplained: the viscera are all so hidden by their situation, that we can hardly have the testimony of our senses for any of their functions in man. The physiologist supplies this deficiency by experiments on living animals, in whom he exposes the various internal organs, and observes the consequences of circumstances altered and combined at his pleasure. It is not our business to consider here, whether this use of sentient beings is morally justifiable; or whether it may be advantageous to the individual or society, to stifle that internal voice which remonstrates most loudly in every mind not accustomed to acts of cruelty, against the infliction of pain on beings who seem to feel it as acutely as ourselves: we have only to observe that these proceedings, however afflicting to the humane, are full of physiological instruction. A comparison of the structure and functions of animals in all classes of the animal kingdom, is another most important source of physiological knowledge. The aid of chemistry is indispensible to the physiologist in the subjects of respiration, perspiration, and the secretions; indeed in unfolding the structure of the body in general.

We must refer the reader to various articles of this Cyclopædia, for an account of the physiology of man. Under Life and Fibre he will find general views of the structure and actions of the body; and under Function, a classification of the functions. The physiology of the thoracic organs will be found under Heart, Circulation, Lungs, and Respiration; of the lymphatic system, under Absorbents and Absorption; of the blood-vessels, under Heart and Artery; of the brain, nerves, and muscles, under Brain, Nervous *System*, and Muscle; of the mechanical preparation of the food, and its descent into the stomach, under Deglutition; of the changes wrought on it in the alimentary canal, under Digestion. Further remarks on subjects connected with this will be found under Liver, Spleen, Pancreas, Stomach, and Intestines. The physiology of the urinary apparatus is considered under Kidney. The functions of the organs of sense are explained under Integuments, Eye, Ear, Nose, and Tongue; and those of the generative organs, under Generation and Embryo. Various physiological points are considered under Gland, Larynx, Membrane, and Death; also under the article Man. We may also refer to to BONE, CARTILAGE, CELLULAR *Subſtance*, CRANIUM, and other anatomical articles.

The Inſtitutiones Phyſiologicæ of Blumenbach is the beſt compendium of this ſcience: it is executed with brevity and great neatneſs, and is remarkable for the ſmall quantity of objectionable matter it contains. Its well ſelected references will lead the ſtudent to the beſt ſources of more detailed information. The Firſt Lines of Haller, and the Elements of Phyſiology of Richerand, are inferior to the above-mentioned claſſical production of Blumenbach. The Elementa Phyſiologiæ of Haller is a moſt accurate and uſeful repoſitory of all the facts and opinions relating to phyſiological ſcience up to the period of its publication, and ſuperſedes the neceſſity of all works previous to that date. The works of John Hunter and of Bichat (his Anatomie Generale, and Recherches ſur la Vie et la Mort), the Syſtem of Phyſiology of Dumas, the Leçons d'Anatomie comparée of Cuvier, and the Manual of the ſame ſcience of Blumenbach, with various detached papers in the collections of learned ſocieties in this and foreign countries, are the beſt ſources of information ſubſequent to the work of Haller. More particular references will be found in the different articles.

PHYSKIUM, in *Botany*, φυςκιον, *a little bladder*, is a genus of Loureiro's, found in the waters of Cochinchina, which by his characters and deſcription appears to be very near the *Valiſneria octandra*, Roxb. Coromand. v. 2. 34. t. 165, and probably may be the very ſame plant.

PHYSOCELE, from φυσα, *flatus*, and κηλη, *a tumour*, in *Surgery*, a ſwelling occaſioned by air. See EMPHYSEMA.

PHYSOMETRA, in *Medicine*, from φυσαω, *to inflate*, and μητρα, *the womb*, a tympany of the womb, occaſioned by air diſtending that organ. This is, at all events, a very rare diſeaſe, and the accounts given of it by the older authors have probably originated in miſtake. Air, however, appears to be occaſionally generated in the internal cavities of the living body, as Mr. John Hunter ſuggeſted, by a ſort of ſecretion from the blood-veſſels. Sauvages mentions two varieties of the diſeaſe. Noſol. Method. Claſs x. Gen. 14.

PHYSOSPERMUM, in *Botany*, from φυσαω, *to inflate*, and σπερμα, *ſeed*, a genus ſo named by Cuſſon, who removed it from LIGUSTICUM, (ſee that article,) principally on account of the double ſkin of the ſeed, the outer coat being ſeparated by a ſmall cavity from the inner. The plant, on which this ſuppoſed genus depends, is no other than the ſo much talked of, and long ſo little known, *L. cornubienſe* of Linnæus and Fl. Brit. the *L. alterum*, Lob. Ic. 786; ſee Juſſ. Gen. 222.

PHYSSOPHORA, in *Natural Hiſtory*, a genus of the claſs and order Vermes Molluſca. The generic character is this; body gelatinous, pendent from an aerial veſicle, with gelatinous ſeſſile members at the ſides, and numerous tentacula beneath. There are three ſpecies. They are all nearly allied to the Meduſæ, and might perhaps without much impropriety be removed to that genus.

Species.

HYDROSTATICA. Oval; with numerous, lateral, three-lobed veſicles, open outwardly; middle inteſtine and four larger tentacula red. It inhabits the Mediterranean; is about half an inch long, compreſſed, and always ſwims with the tip of the veſicle above the water.

ROSACEA. Orbicular, and imbricate with oblong, horizontal, foliaceous membranes affixed to the veſicle. It is found in the Mediterranean. The body is hyaline, an inch in diameter, and reſembles a full blown flower bending downwards. The veſicle is obtuſe, ovate, reddiſh, and covered with flat, obtuſe, foliaceous membranes, curved and thickly laid.

FILIFORMIS. Lateral members oblong, filiform, and pendent. This is found in the Mediterranean. The body is very tender, not thicker than a thread, and a ſpan long, hyaline, with an obtuſe ovate head, about the ſize of a grain of rice.

PHYSTA, in *Ichthyology*, a name given by Geſner, and ſome others, to the fiſh called by the Greeks, and many of the later authors, *ballerus* and *balerus*. Artedi denies its right to any generical name, reducing it to the genus of the cyprini, to which it evidently belongs, and diſtinguiſhing it from the others of that numerous genus by the ſpecific name of the very broad and thin cyprinus, with forty rays in the pinna ani. See CYPRINUS.

PHYSTE, in the *Writings of the Ancient Phyſicians*, a word uſed to expreſs a maſs of meal macerated in a cloſe veſſel with wine, but not left to ferment.

PHYTALIA, a word uſed by the ancients in two very different ſenſes; with ſome expreſſing the latter part of the winter ſeaſon, and with others a place where vines are planted, whether in ſtandard vineyards or otherwiſe.

PHYTEUMA, in *Botany*, a name adopted from Dioſcorides, whoſe φυτευμα, whatever it may have been, appears to have received that appellation from φυτευω, *to ſow* or *plant*. Some have ſuppoſed an alluſion to the reputed qualities of the herb as a philter, which Dioſcorides and Pliny mention. We can trace no reaſon for the Linnæan application of the name, except perhaps in the fiſſures or perforations of the fruit of our *Phyteuma*, to which the Greek deſcription ſeems to allude. Linn. Gen. 89. Schreb. 118. Willd. Sp. Pl. v. 1. 919. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 354. Sm. Fl. Brit. 240. Prodr. Fl. Græc. Sibth. v. 1. 143. Juſſ. 165. Lamarck Illuſtr. t. 124. Gærtn. t. 30.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, in five deep, acute, ſomewhat ſpreading ſegments. *Cor.* of one petal, wheel-ſhaped, ſpreading, in five deep, linear, acute, recurved ſegments. *Stam.* Filaments five, ſhorter than the corolla; anthers oblong. *Piſt.* Germen inferior, roundiſh; ſtyle thread-ſhaped, the length of the corolla, recurved; ſtigma in two or three oblong revolute ſegments. *Peric.* Capſule roundiſh, membranous, of two or three cells, opening by a fiſſure at each ſide. *Seeds* very numerous, ſmall, roundiſh, ſmooth.

Eſſ. Ch. Corolla wheel-ſhaped, in five deep linear ſegments. Stigma in two or three ſegments. Capſule inferior, opening laterally, of two or three cells.

A genus of herbaceous, almoſt uniformly perennial, mountain or alpine, European plants, with handſome blue flowers; nearly allied to *Campanula*, but with a differently ſhaped corolla. Willdenow well remarks, that the alpine ſpecies, and indeed all that are the produce of the more northern or middle regions of Europe, bear a denſe oblong ſpike, or roundiſh head; while the oriental ones generally have diſperſed flowers. In ſenſible qualities the genus agrees with *Campanula;* and the herbage, when wounded, diſcharges a bitter milky fluid. Linnæus has ſix ſpecies in his Sp. Pl. and the ſame number in Syſt. Veg. ed. 14. Willdenow has ſixteen. One only is wild in Britain. Five exotic ſpecies occur in Hort. Kew. one of them before publiſhed by Dr. Sims alone. Three are added to the ſtock in Prodr. Fl. Græcæ, of which one is *Campanula limonifolia* of Linnæus and Willdenow. The alpine ſpecies are,

are, in many inftances, not free from obfcurity in their characters and fynonyms, as being liable to vary much, according to fhade or expofure of fituation, in the fhape of their leaves, length and figure of their fpikes, as well as in their whole habit and dimenfions. Hence arifes fo much obfcurity in their determination, that though we have examined not a few in their native ftations, and have received fome authentic fpecimens from the authors, who have defcribed them, the difficulty of arranging their fynonyms, and defining their limits, feems rather to grow under our hands. We fhall attempt to correct fome errors, in enumerating a few of the moft certain fpecies. There can be no good reafon for perfevering in the old blunder of making *Phyteuma* of the feminine gender.

Ph. *Scheuchzeri.* Willd. n. 2. Allion. Pedem. v. 1. 116. t. 39. f. 2. (Rapunculus, n. 682; Hall. Hift. v. 1. 304.)—Flowers in a round head, much exceeded by the long, linear, fpreading bracteas. Stem leafy. Leaves linear-lanceolate, toothed, ftalked, rough-edged.—Native of the alps of Switzerland and Savoy.—*Stem* from twelve to eighteen inches high, upright, weak, flender, fmooth, fimple. *Leaves* from one to three inches long, fcattered, narrow, bluntifh, minutely rough at the edges, and befet with glandular diftant teeth. *Flowers* not very numerous, in a perfectly round, folitary, terminal head. *Bracteas* few, one much longer, and more leafy, than the reft. *Style* flender, hairy upwards. *Style* long, three-cleft, revolute.

Ph. *fcorzonerifolium.* Villars Dauph. v. 1. 519. t. 12. f. 2.—Spike cylindrical. Bracteas fhort, reflexed. Stem naked above. Leaves linear-lanceolate, toothed, fmooth.—Native of the mountains of Dauphiny and Italy. We gathered it on the hill called *la Bocchetta*, above Genoa, in 1787. Willdenow confiders this as but a variety of the former, to which he was perhaps led by an affertion of Villars, that it was fent by Allioni as his *Ph. Scheuchzeri.* Here muft have been fome miftake. The two fpecies are effentially diftinct in their inflorefcence, and all the reft of the characters indicated above. The fpike in our Genoefe fpecimens is in feed, and meafures near two inches in length, though only a quarter of an inch in thicknefs. The *ftem-leaves* are moftly feffile, quite fmooth at the edges, numerous about the lower part of the *ftem*, though wanting in the upper. Their teeth are more like ferratures.

Ph. *hemifphæricum.* Grafs-leaved Rampion. Linn. Sp. Pl. 241. Willd. n. 4. Ait. n. 1. Jacq. Ic. Rar. t. 333.—Head roundifh. Bracteas ovate, pointed. Leaves linear, nearly entire, about as long as the ftem.—Native of the alps of Switzerland, Italy, France, and Germany, as well as of the Pyrenees. It has been introduced from time to time into our gardens, but requires the fhelter of a frame, like many other alpine productions, that are fo long buried in fnow in their native ftations. The *roots* are fomewhat creeping. *Stems* from two to fix inches high, afcending or curved, concealed by the numerous, chiefly radical, narrow, fmooth *leaves*, which fometimes overtop them, and whofe graffy afpect characterifes this fpecies. The *bracteas* are feveral, fhorter than the head, broad, taper-pointed, fomewhat membranous, fringed. Two or three of the very earlieft *leaves* are often fhort and fpatulate.

Ph. *comofum.* Glaucous Rampion. Linn. Sp. Pl. 242. Willd. n. 5. Ait. n. 2. Jacq. Auftr. append. 56. t. 50.—Flowers in a terminal leafy tuft. Leaves ftrongly toothed, fmooth, glaucous; the radical ones heart-fhaped.—This beautiful fpecies, fo remarkable for its very glaucous *herbage*, and purple inflated *flowers*, was firft found on mount Baldus. It occurs alfo on the alps of Carniola and the Tyrol, but fcarcely elfewhere. The *ftem* is but three or four inches high. *Leaves* broad, moftly elliptical. No obfcurity attends this plant, of which many figures are to be found in the old authors. We have never feen a garden fpecimen. The *root* is biennial.

Ph. *orbiculare.* Round-headed Rampion. Linn. Sp. Pl. 242. Willd. n. 6. Ait. n. 3. Jacq. Auftr. t. 437. Engl. Bot. t. 142.—Head roundifh. Leaves crenate; the loweft fomewhat heart-fhaped; the uppermoft feffile, ovate, pointed.—Found on the mountains of Italy and Switzerland, as well as on the chalky hills of Suffex and Surry, being the only Britifh fpecies. It flowers in Auguft, and is perennial. The firft or loweft *leaves* only are heart-fhaped; the reft of the radical ones elliptic-oblong; all crenate, veiny, flightly roughifh: the *ftem-leaves* are fcattered, feffile, fmall, lanceolate or ovate, taper-pointed. *Stem* about a foot high, in luxuriant ground twice as much, crowned with a denfe head of numerous dark-blue *flowers*, fubtended by feveral ovate fringed *bracteas.*—Willdenow fubjoins as varieties three fpecies of Villars, which we can fcarcely think belong to *orbiculare*, though we have not had an opportunity of feeing more than two of them. *Ph. lanceolatum*, Villars t. 12. f. 1, we have not feen, but the uniformly ovate *leaves*, all ftalked, indicate a ftrong fpecific difference from our *orbiculare*. *Ph. ellipticum*, t. 11. f. 2, is ftill more different, in its fhort denfe hairinefs, as well as in its oblong blunt upper *leaves*, and long leafy *bracteas*. *Ph. Charmelii*, t. 11. f. 3, is abundantly diftinct from all thefe, in its fmall, violet-like, heart-fhaped, radical *leaves*, rough with minute points, and fupported by capillary *footftalks*, above five times their own length; as well as in its humble *ftem*, bearing many long, narrow, lanceolate or linear *leaves*, and the long narrow *bracteas* which accompany its fmall denfe head of *flowers*.

Ph. *repandum.* Olympian Rampion. Sm. Prodr. Fl. Græc. Sibth. v. 1. 143.—Spike rather lax. Leaves elliptic-oblong, ftalked, wavy, fmooth. Stem perfectly fimple, almoft leaflefs.—Gathered by Dr. Sibthorp on the fummit of the Bithynian Olympus. The *root* is ftrong, woody, and perennial, producing many tufts of *leaves* not unlike thofe of *Globularia nudicaulis*, but lefs coriaceous, and fomewhat wavy at the margin. *Stems* folitary, erect, ftraight, two, three, or four inches high, fmooth, bearing one or two diftant leaves. The *footftalks* are all fringed at the bafe. *Flowers* blue, in a folitary, erect, lax *fpike*, the lower ones often in pairs, and fometimes very remote. *Bracteas* linear-lanceolate, fringed. This fpecies is no where figured.

Ph. *ellipticum.* Elliptical Mountain Rampion. Sm. Prodr. Fl. Græc. Sibth. v. 1. 143. Fl. Græc. t. 217. unpubl. (Ph. campanuloides; Sims in Curt. Mag. t. 1015. Ait. n. 5.)—Spike rather lax. Leaves elliptical, ftalked, crenate, rough. Stem perfectly fimple, leafy, hairy.—Native of the Bithynian Olympus and of mount Caucafus. The *root* is fomewhat creeping. *Stems*, in the wild plant, from fix to twelve inches high, erect, more or lefs rough with hoary denfe hairs, and bearing many elliptic or ovate, ftrongly crenate, roughifh *leaves*, about an inch and a half long, on fringed *footftalks* of various lengths. *Flowers* deep blue, in a terminal bracteated *fpike*, extremely variable in length and luxuriance. In a garden, it feems, the *ftem* becomes fmooth, and the *fpike* racemofe, with ternate *flowers*, which laft character occafionally prefents itfelf likewife in wild fpecimens. Dr. Sibthorp's figure, with about feven flowers, and that in the Botanical Magazine, exhibit the two extremes of the inflorefcence. Our fpecimens account for the appellation of *canefcens*, under which Mr. Loddiges received the plant; and it is much to be wifhed that our ſpecific name, antecedent to that in the Magazine, might alſo take place of the probably unpubliſhed Flora Taurica, *campanuloides* being liable to ſeveral objections.

Ph. *betonicifolium*, Villars Dauph. v. 2. 518. t. 12. f. 3; *ſpicatum*, Linn. Sp. Pl. 242. Fl. Dan. t. 362; and *ovatum*, Willd. n. 10, which laſt is Haller's Rapunculus n. 683, are ſufficiently defined in Willdenow, nor does any obſcurity attend theſe ſpecies.

Ph. *limonifolium*. Sea-lavender Rampion. Sm. Prodr. Fl. Græc. Sibth. v. 1. 144. Fl. Græc. t. 218, unpubl. (Campanula limonifolia; Linn. Sp. Pl. 239. Willd. Sp. Pl. v. 1. 914. C. orientalis, limonii minimi facie, flore patulo; Tourn. Cor. 3.)—Leaves lanceolate, roughiſh with reverſed hairs, wavy, and ſomewhat toothed. Stem panicled. Flowers ſeſſile, about three together.—Gathered by Tournefort in the Levant; by Sibthorp in graſſy places towards the ſummit of the Bithynian Olympus. The *root* is very thick and woody, crowned with numerous tufts of narrow, bluntiſh, long-ſtalked, ſpreading *leaves*, about three inches long, and half an inch wide, of a bright green; their ſhort rigid pubeſcence directed backwards, or towards the baſe; their margin either toothed or waved. *Stems* about a foot high, erect, round, ſmooth, leafy, copiouſly branched in an alternate manner; their *branches* ſpreading, leafleſs, beſet with many ſmalliſh, blue, ſeſſile *flowers*, two or three together, having yellow *anthers*, and a rough, reddiſh, club-ſhaped *ſtyle*.

Ph. *lobelioides*. Willd. n. 12. Phytogr. faſc. 1. 6. t. 4. f. 2. (Rapunculus orientalis, heſperidis folio; Tourn. Cor. 4.)—Leaves linear-lanceolate, ſomewhat toothed, rough. Stem panicled. Flowers ſtalked, ſcattered.—Gathered by Tournefort in America. It is very remarkable that ſo great a *corolliſt* ſhould have ſeparated this plant generically from the laſt, their *flowers* agreeing ſo exactly in the depth of their ſegments. Indeed they come ſo near in ſpecific characters, that but for the different diſtributions of their *flowers*, which ſeems conſtant, we could hardly have diſtinguiſhed them.

Ph. *amplexicaule*. Toothed Rampion. Willd. n. 15. Sm. Fl. Græc. Sibth. t. 219, unpubl. (Rapunculus orientalis, campanulæ pratenſis folio; Tourn. Cor. 4.)—Leaves ovate, pointed, ſtrongly and doubly ſerrated, ſmooth; ſlightly heart-ſhaped, and claſping the ſtem. Cluſter leafy, ſomewhat panicled.—Gathered by Dr. Sibthorp, in graſſy ſpots, near the top of the Bithynian Olympus. A very handſome ſpecies, twelve or eighteen inches high, ſmooth and unbranched, with numerous, alternate, ſtrongly and ſharply ſerrated, or toothed, *leaves*, about two inches long. *Flowers* large, bright blue, vying in beauty with the following, but far leſs numerous.

Ph. *pinnatum*. Winged-leaved Rampion. Linn. Sp. Pl. 242. Willd. n. 16. Ait. n. 6. Venten. Jard. de Cels. t. 52. Sm. Fl. Græc. Sibth. t. 220, unpubl. (Rapunculus creticus, ſeu Pyramidalis altera; Tourn. Inſt. 113. Petromarula di Candia, overo lattuca petrea; Pon. Bald. 96. Imperati Hiſt. Nat. 668.)—Leaves pinnate. Panicle cylindrical, branched, many-flowered.—Very common on the rocks and mountains of Crete, but does not appear to be found wild any where elſe. Parkinſon is ſaid to have cultivated this beautiful plant in 1640; but it had long been loſt to our collections, till Dr. Sibthorp brought ſeeds, which produced flowering plants at Dr. Pitcairn's, Iſlington, from whom we obtained a ſpecimen in 1791, there being none previouſly in the Linnæan herbarium. The wooden cuts of Pona and Imperati are good and original; but the beſt hiſtory of the plant is given, from Honorius Belli's letter to Cluſius, by the former. This all writers have copied, and Ventenat attributes the credit of ſome of it to J. Bauhin, who certainly has nothing original on the ſubject. Ventenat alſo errs, in his own obſervation, when he ſays the ſimple ſtigma diſagrees with the character of *Phyteuma*. But this part, though drawn ſimply capitate in his plate, is truly three-cleft, as drawn by Bauer. The *root* is perennial, thick and milky, eaten, like that of *Campanula Rapunculus*, being ſuppoſed of an aphrodiſiac quality. The firſt *leaves* are ſimply heart-ſhaped, like thoſe of violets; the reſt pinnate, ſometimes interruptedly, a ſpan long, ſmooth, deeply ſerrated; pale, and often purpliſh, beneath; their terminal leaflet heart-ſhaped, the reſt obliquely ovate, ſtalked. *Flowers* very abundant, in a long, erect, terminal, denſe, *panicle*, with cymoſe branches; their ſtalks glaucous and purpliſh; their *corolla* and *ſtamens* of a lilac hue.

PHYTOLACCA was firſt ſo called by Tournefort, from φυτὸν, *a plant*, and *lacca*, a barbarous word, deſignating a kind of colouring ſubſtance; ſee LAKE or LAQUE; becauſe the berries of ſeveral ſpecies of this genus afford a beautiful, though not laſting, purple or crimſon dye.—Tourn. t. 154. Linn. Gen. 233. Schreb. 313. Willd. Sp. Pl. v. 2. 822. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 139. Sm. Prodr. Fl. Græc. Sibth. v. 1. 318. Juſſ. 84. Lamarck Illuſtr. t. 393. Gærtn. t. 77.—Claſs and order, *Decandria Decagynia*. Nat. Ord. *Holeraceæ*, Linn. *Atriplices*, Juſſ.

Gen. Ch. *Cal.* inferior, of five roundiſh, concave, ſpreading, coloured, permanent leaves, inflexed at the ſummit. *Cor.* none. *Stam.* Filaments ten, or eight, or twenty, awl-ſhaped, the length of the calyx; anthers roundiſh, lateral. *Piſt.* Germen ſuperior, orbicular, depreſſed, marked with alternate furrows and ribs; crowned with ten, or eight, or five, or ſeven, very ſhort, ſpreading, reflexed ſtyles; ſtigmas ſimple, permanent. *Peric.* Berry orbicular, depreſſed, furrowed, with ten, or eight, or five, or ſeven, cells, the ſummit hollowed, lodging the ſtyles. *Seeds* ſolitary in each cell, kidney-ſhaped, ſmooth.

Obſ. *Ph. dioica* has the flowers of diſtinct ſexes, on different plants. Linnæus having now fixed the place of this genus, amongſt his *Holeraceæ*, not *Miſcellaneæ*, it becomes neceſſary to reform his generic character, as to the flower having a *calyx*, not a *corolla*, on which ſubject he ſpeaks with doubt in his Gen. Pl.

Eſſ. Ch. Calyx of five coloured leaves. Corolla none. Berry ſuperior, of five or ten cells, and as many ſeeds.

The genus before us is remarkable for having all its ſpecific differences depend on the number or ſituation of the organs of impregnation; ſo that, ſtrictly ſpeaking, every ſpecies belongs to a different claſs or order of the artificial ſyſtem. No genus, notwithſtanding this irregularity, can be more natural. Linnæus knew but four ſpecies; Willdenow has ſix, five of them in the gardens of England. It is worthy of remark, that the two new ſpecies, diſcovered ſince Linnæus wrote, differ in the number of their ſtamens and ſtyles from each other, as well as from all thoſe originally deſcribed, ſo as to preſerve the unity of the principle according to which they are all diſcriminated.

1. Ph. *octandra*. White-flowered Phytolacca, or Poke-weed. Linn. Sp. Pl. 631. Willd. n. 1. Ait. n. 1. (Ph. mexicana, baccis ſeſſilibus; Dill. Elth. 218. t. 239. f. 308. Sjoorikii, vulgò Jamma Gobó; Kæmpf. Amoen. 828. t. 829.)—Stamens and ſtyles eight.—Native of Mexico, as well as of Japan. The *root* is perennial, long and fleſhy, according to Kæmpfer eatable, and like a turnip. *Stem* herbaceous, thick, fleſhy, alternately branched, leafy, ſmooth,

ſmooth, from three to ſix feet high. *Leaves* alternate, ovate, with a glandular point, ſmooth, wavy, veiny, reſembling thoſe of a *Rumex* or *Beta*, on thick ſtalks. *Flowers* white, numerous, in denſe, cylindrical, terminal, ſolitary ſpikes. *Berries* ſeſſile, black, the ſize of a large pea. The whole plant has a coarſe rank habit, like a dunghill herb, and ſmells unpleaſantly when bruiſed.

2. Ph. *ſtricta*. Erect Phytolacca. Willd. n. 2. Hoffm. Comm. Goett. v. 12. 27. t. 3. (Ph. heptandra; Retz. Obſ. faſc. 6. 29.)—"Stamens eight. Styles ſeven. Leaves lanceolate, pointed."—Native of America. We have ſeen no ſpecimen. Retzius deſcribes it as follows. *Root* perennial. *Stem* two feet high, branched, erect, ſtriated, ſmooth, hollow. *Leaves* ſcattered, ſtalked, lanceolate, entire, ſmooth, an inch and a half long. *Flowers* racemoſe, with ſeveral ſmall awl-ſhaped *bracteas*, at or near the baſe of their partial ſtalks. *Calyx* white within. *Stamens* ſeven. *Styles* ſix. *Berries* yellow, pellucid, of ſix diſtinct lobes, or grains. Hoffmann and Willdenow both give the number of *ſtamens* and *ſtyles* as above.

3. Ph. *abyſſinica*. African Phytolacca. Willd. n. 3. Ait. n. 2. Hoffm. Comm. Goett. v. 12. 28. t. 2. (Ph. dodecandra; L'Herit. Stirp. 143. t. 69.)—Stamens ten. Styles five. Said to have been brought from Abyſſinia, by Mr. Bruce, in 1775. It is a ſhrub, kept in the ſtove, and flowering in May and June. *Stem* ſix feet high. *Branches* ſlender and ſpreading. *Leaves* ſtalked, ſpreading, ovate, wavy, tipped with an acute, reflexed, channelled point. *Cluſters* long, drooping, downy, of many greeniſh downy *flowers*. *Berry* deeply lobed, red, with orange-coloured juice. L'Heritier found the *ſtyles* and *ſeeds* moſt commonly but five; the *ſtamens* uſually fifteen. Both are acknowledged to be variable. Our garden ſpecimen, in the collection of the younger Linnæus, bears the name of *Ph. ſcandens*, which we find no where in print, nor does it ſeem to agree with the character of the ſhrub.

4. Ph. *decandra*. Common Phytolacca, or Virginian Poke-weed. Linn. Sp. Pl. 631. Willd. n. 4. Ait. n. 3. Curt. Mag. t. 931. Mill. Illuſtr. t. 36.—Stamens and ſtyles ten.—Native of America, now naturaliſed in Spain, Portugal, Barbary, Zante and Greece. With us it is a tolerably hardy perennial, flowering from July to the end of autumn, forming a large herbaceous buſh, decorated at once with cluſters of greeniſh-white *flowers* and dark purple *berries*. The latter are ſaid to have ſometimes ſerved in Portugal to improve the colour of ſuch red port as is compounded in that country, not in England.

5. Ph. *icoſandra*. Red Phytolacca. Linn. Sp. Pl. 631. Willd. n. 5. Ait. n. 4. (Ph. ſpicis florum longiſſimis, radice annua; Mill. Ic. v. 2. 138. t. 207.)—Stamens twenty. Styles ten.—Native of the Eaſt Indies. Annual with us, if planted abroad; but perennial in a ſtove, flowering in autumn. The *ſtem* is herbaceous, three or four feet high. *Leaves* rather narrower than in the laſt. *Cluſters* erect, long, and taper-pointed, of numerous bluſh-coloured *flowers*, the lowermoſt of which, Linnæus ſays, have certainly twenty *ſtamens*. By Miller's account the generality have much fewer. *Berries* dark purple, on rather ſhort partial ſtalks.

6. Ph. *dioica*. Tree Phytolacca. Linn. Sp. Pl. 632. Willd. n. 6. Ait. n. 5. L'Herit. Stirp. 145. t. 70.—Flowers dioecious, with many ſtamens.—Native of South America. Miller cultivated this ſpecies in 1758, and L'Heritier ſays it is extremely common in European gardens. The Hortus Kewenſis marks it as a ſtove ſhrub, without any mention of its flowering. The *ſtem* is thick, ten or twelve feet high, with round ſmooth leafy branches. *Leaves* preciſely ovate, pointed, ſmooth, entire, on long ſtalks. *Cluſters* drooping, ſomewhat downy. *Flowers* greeniſh-white; the female ones ſmalleſt. *Berries* large, crowded, pale, much depreſſed and umbilicated.

The *leaves* of all the ſpecies that we have ſeen terminate in an awl-ſhaped, channelled, pale or coloured, ſomewhat glandular point, or appendage, which ſeems characteriſtic of the genus.

Phytolacca, in *Gardening*, affords plants of the herbaceous hardy kinds, of which the ſpecies cultivated are; the white-flowered phytolacca (P. octandra); the branching phytolacca, or Virginian poke (P. decandra); the red phytolacca (P. icoſandra); and the tree phytolacca (P. dioica).

The firſt ſort is in ſome places found a palatable wholeſome green: the tender ſtalks being frequently ſerved up as young aſparagus.

Alſo, in ſome places the young ſhoots of the ſecond ſort are boiled and eaten as ſpinach.

The fruit in the third ſort is a globular berry.

Method of Culture.—The three firſt ſorts may be increaſed by ſeeds, which ſhould be ſown in pots, in the ſpring, and plunged in a moderate hot-bed; when the plants have had a few inches growth, they ſhould be removed into ſeparate pots in the firſt and third ſorts, but in the ſecond into the borders or other parts, allowing them good room. The two former may be ſet out in warm borders or other places during the ſummer in pots, being carefully watered, ſhaded, and kept free from weeds.

The fourth ſort may be raiſed by planting cuttings in the ſummer ſeaſon, in pots filled with light earth, plunging them in the bark hot-bed and covering the pots with hand-glaſſes, proper ſhade being given. When well rooted, they ſhould be removed into ſeparate pots of a ſmall ſize, replunging them in the hot-bed with proper ſhade till rooted, when they ſhould be gradually inured to the open air, being removed into a moderate ſtove during the winter ſeaſon.

The firſt ſorts afford ornament and variety among potted plants of the ſtove kind; and the ſecond ſort, in the borders of the natural ground.

PHYTOLOGI, Phytologists, authors who have written any treatiſe on botany, or the hiſtory or uſes of vegetables.

PHYTOLOGY, Φυτολογια, compounded of φυτον, *plant*, and λογος, *diſcourſe*, of λεγω, *I deſcribe*, or *rehearſe*, a diſcourſe upon plants, or a deſcription of their forms, kinds, properties, &c.

PHYTOTOMA, in *Ornithology*, a genus of birds of the order Paſſeres. The generic character is; bill conic, ſtraight, ſerrate; noſtrils oval; tongue ſhort and obtuſe; feet four-toed. There is but a ſingle ſpecies; *viz.*

Rara, which inhabits Chili, about the ſize of a quail; it has a harſh interrupted cry, reſembling the ſyllables *ra ra*; it feeds on freſh vegetables, which it cuts down near the roots with its bill as with a ſaw, and is, on account of the miſchief which it does to gardens, deteſted by the natives: it builds in high ſhady trees in retired places; the eggs are white, ſpotted with red. The bill of this bird is thick, and about half an inch long, toothed on each ſide like a ſaw; the irides are brown; the body above is of a duſky aſh, beneath it is paler; the quill and tail-feathers are ſpotted with black; tail rounded; the hind toes ſhorter than the fore ones.

PHYZANIA, in *Ancient Geography*, the name of a country of Africa, according to Ptolemy.

PIA Mater, in *Anatomy*, one of the coverings of the brain. See Brain and Nervous *Syſtem*.

PIABA, in *Ichthyology*, the name of a ſmall freſh-water fiſh, caught in all the rivers and brooks in the Braſils, and ſome other parts of America.

It is of the ſize of the common minow; is a well-taſted fiſh, and much eſteemed by the natives.

PIABUCU, the name of an American fiſh eaten by the natives in many places. It is a ravenous fiſh, and ſo greedy of blood, that if a man goes into the water with a wound in any part of his body, this fiſh will make up to it to ſuck the blood: it is a ſmall fiſh, ſeldom exceeding four inches in length. See Salmo *Argentinus*.

PIACENZA, in *Geography*. See Placentia.

PIACHE, Piazza, a covered arched walk, or portico. See Portico and Piazza.

PIADA, in *Ancient Geography*, a town of Aſia, in Serica, between Damna and Aſmiræa. Ptolemy.

PIADELLA, in *Geography*, a town of Italy, in the department of the Lario; 20 miles N. of Como.

PIADENA, a town of Italy, in the department of the Mincio; 16 miles W. of Mantua.

PIAFFEUR, in the *Manege*, is a proud, ſtately horſe, being full of mettle, or fire, reſtleſs and forward, with a great deal of motion, and an exceſſive eagerneſs to go forwards, makes this motion the more that you endeavour to keep him in, and bends his leg up to his belly. He ſnorts, traverſes if he can, and by his fiery action ſhews his reſtleſſneſs; whence ſome, though very improperly, ſay, he dances.

Such horſes as theſe, or ſuch as are bred to paſſage upon a ſtraight line, are much admired in carouſals and magnificent feſtivals. See Snort, and Passade.

PIALAPOUR, in *Geography*, a town of Bengal; 20 miles N. of Dacca. N. lat. 23° 35′. E. long. 90° 8′.

PIALITZ, a river of Ruſſia, in the government of Archangel, on the coaſt of the White ſea, near Pialitza. N. lat. 66° 10′. E. long. 37° 44′.

PIALITZA, a town of Ruſſia, in the government of Archangel, on the coaſt of the White ſea; 100 miles N. of Archangel.

PIAL-UL-GEEL, a town of Pruſſia, in the circle of Natangen; 10 miles E. of Lick.

PIALZY, a town of Hindooſtan, in the country of Dindigul; 23 miles W.N.W. of Dindigul. N. lat. 10° 28′. E. long. 17° 37′.

PIANA, a town of the iſland of Corſica; nine miles N.W. of Vico.—Alſo, a river of Ruſſia, which runs into the Sura, near Yadrin, in the government of Kazan.—Alſo, a ſmall iſland near the N. coaſt of Sardinia. N. lat. 41°. E. long. 8° 27′.—Alſo, a ſmall iſland near the W. coaſt of Sardinia. N. lat. 39° 17′. E. long. 8° 25′.—Alſo, a ſmall iſland in the Mediterranean, near the coaſt of Naples. N. lat. 40° 13′. E. long. 12° 55′.

PIANEG, a town of Ruſſia, in the government of Viatka; 16 miles E.N.E. of Yarenſk.

PIANELLO, a town of the iſland of Corſica; 18 miles E. of Corte.

PIANEZZA, a town of France, on the Dora; four miles W. of Turin.

PIANISSIMO, in the *Italian Muſic*. See Piano.

PIANKANSHAWS, or Pyankeshaws, *Vermilions* and *Muſcontins*, in *Geography*, are tribes of Indians in the Indiana territory, who reſide on the Wabaſh and its branches, and Illinois river. Theſe, with the Kickapoos, Muſquitons, and Ouiatanons, could together furniſh about 1250 warriors, in the year 1780.

PIANKATUNK, a ſmall river of Virginia, which runs E. into Cheſapeak bay, oppoſite to Gwin's iſland; navigable eight miles for ſmall craft.

PIANO, a town of Italy, in the department of the Panaro; 16 miles S.W. of Modena.

Piano *della Corte*, a town of Naples, in Principato Citra; 12 miles N.N.W. of Cangiano.

Piano *Picola*, a town of Naples, in Capitanata; two miles W. of Vieſte.

Piano, an Italian muſical term implying ſoft, with a ſubdued voice, was at firſt only uſed in repeating ſhort paſſages in the way of echo. It was no otherwiſe uſed by Corelli. At preſent its uſe is extended to whole periods in the way of chiaro-ſcuro, and contraſt to *forte*, loud, in every degree of compariſon. It is abridged to *pia*, and the initial letter P., as is its ſuperlative degree, *pianiſſimo*, to *pianiſs*, and *pp*. Sometimes *pp*. ſtands for *pian piano*, when it has ſomewhat more force.

Piano *Forte*, a keyed inſtrument, of which the tone is produced by hammers inſtead of quills, like the virginal, ſpinet, and harpſichord. There is a minute account of the invention, and a deſcription of the piano forte, in the "Giornale d'Italia," tom. v. p. 144, printed at Venice, 1711. This inſtrument was invented at Florence, by Bartolommeo Criſtofali, harpſichord maker, a native of Padua, in the ſervice of the grand duke of Tuſcany. For the hiſtory of the piano forte, ſee Harpsichord.

PIANOSA, in *Geography*, a ſmall iſland in the Mediterranean, near the coaſt of Etruria, anciently called "Plunatia," and uſed as a place of exile. Its flat ſurface is a league in extent, elevated only a few feet above the level of the ſea; an uncultivated rock, abandoned to wild goats; dangerous to navigators in the night; ſeven miles S.S.W. from the iſland of Elbe. N. lat. 42° 42′. E. long. 10° 15′.

PIAPET, or Magpie, in *Ornithology*. See Corvus *Pica*.

PIAPIS Harbour, in *Geography*, a port on the N. coaſt of the iſland of Waygoo, on the Equator. E. long. 130° 45′.

PIAQUEMINES, a river of Louiſiana, which runs into the Miſſouri, N. lat. 38° 25′. W. long. 91° 37′.

PIARANTHUS, in *Botany*, from πιαρος, *fat* or *thick*, and ανθος, *a flower*, a genus ſeparated by Mr. R. Brown from *Stapelia*, becauſe it wants the external crown. Brown Tr. of the Wernerian Society, v. 1. 23. Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ. *Aſclepiadeæ*, Brown.

Eſſ. Ch. Corolla bell-ſhaped, five-cleft, fleſhy, including the column of fructification. Crown of the ſtamens ſingle, of five leaves, toothed at their back. Anthers ſimple at the ſummit. Maſſes of pollen erect, attached by the baſe, cartilaginous and pellucid at one edge. Stigma pointleſs. Follicles . . . .

There are but two certain ſpecies.

1. P. *punctatus*. (Stapelia punctata; Maſſon Stapel. 18. t. 24. Willd. Sp. Pl. v. 1. 1289. Ait. Hort. Kew. v. 2. 92.)—Branches decumbent, jointed. Flower-ſtalks axillary, longer than the corolla. Found by Mr. Maſſon in the Namaqua lands, at the Cape of Good Hope. He ſent it to Kew in 1795, and it flowers there, in the dry ſtove, during moſt part of the autumn. The joints of the *branches* are obovate, ſquariſh, of a dark glaucous green, beſet with numerous prominences, each of which is tipped with a brown tooth. *Flower-ſtalks* axillary from the prominences, ſeveral together, an inch and a half long, ſmooth, purpliſh, ſingle-flowered. *Flowers* about an inch wide; internally pink,

pink, dotted with minute crimfon tubercles: externally whitifh; the fegments fpreading, acute.

2. P. *pullus*. (Stapelia pulla; Maffon Stapel. 21. t. 31. Willd. Sp. Pl. v. 1. 1288. Ait. Hort. Kew. v. 2. 92.)—Branches erect, with about fix angles. Flower-ftalks lateral, fhorter than the corolla. Difcovered by Mr. Maffon in the hot fandy region of Karrò in fouthern Africa. He introduced it at Kew fo early as 1774, and it flowers in Auguft and September in the dry ftove. The *ftems* or *branches* form a thick tuft, about a fpan high, of a light green, flightly glaucous; their angles befet with ftrong brown teeth. *Flowers* two or three together, on fhort fimple ftalks, from the fides of the branch, remote from the teeth. *Corolla* about an inch long, flightly fpreading, acute; dark brown within; whitifh, with five purple ribs, without; the edges revolute.

Thefe plants fo precifely accord with various *Stapeliæ* in every point of habit, that we fhould prefume the finglenefs of the crown can afford no legitimate generic diftinction, any more than the difference between five and ten ftamens in *Ceraftium*, the want or prefence of a nectary in *Tilia*, and other fimilar cafes.

PIASANSKOI, Niznei, in *Geography*, a town of Ruffia, in the government of Tobolfk, near the Frozen fea. N. lat. 69° 16′. E. long. 87° 14′.

Piasanskoi, *Verchnei*, a town of Ruffia, in the government of Tobolfk, near the Frozen ocean. N. lat. 68° 30′. E. long. 87° 14′.

PIASKY, a town of Poland, in the palatinate of Lublin; 12 miles E.S.E. of Lublin.

PIASTER, or Piastre, a Spanifh money, more ordinarily called a *piece of eight*.

PIASTLA, in *Geography*, a town of Mexico, in the province of Chiametlan, on the river Piaftla, which runs into the Pacific ocean, N. lat. 23° 25′. The town is fituated at the diftance of 50 miles N.W. of Chiametlan.—Alfo, a town of Mexico, in the province of Guafteca; 15 miles S. of Panuco.—Alfo, a town of Mexico, in the province of Tlafcala; 55 miles S. of Puebla de los Angelos.

PIASTRE, in *Commerce*. See Piaster, or Piece *of eight*.

Piastre is alfo a money of account and filver coin in Turkey, and the Levant. The piaftre of Aleppo, and of its port, Alexandretta or Scanderoon, is accounted at 80 afpers, or 24 fyainos. The piaftres of Alexandria are valued at 40 medini, each medino being fubdivided into 8 borbi, or 6 forli, or 3 afpers. The piaftre at Algiers is the fame with the *pataca gourda*, which fee. At Grand Cairo accounts are kept, by European merchants, in piaftres of 40 medini; but the Levanters reckon only in medini.

Conftantinople and the whole of Turkey keep accounts in piaftres, commonly called grouch by the Turks, and by the Englifh, dollars. Each piaftre is divided into 40 paras, and each para into three afpers. Thefe are real coins; but the piaftre is alfo fometimes divided into 80, and fometimes into 100 imaginary parts, called afpers or minas. A jux or juck is a fum of 100,000 real afpers: a chife or purfe is 500 ditto. The gold coin, called fequin fonducli, was coined in 1764; 100 of thefe weigh 5415 Englifh grains, and they are about 23 carats fine; it paffed at firft for $3\frac{1}{2}$ piaftres, or 440 afpers, but its price was gradually raifed to four piaftres; and in 1769 moft of them were called in for a new coinage. The dollar or piaftre is a filver coin of 40 paras. By the regulations of 1780, the purfe of 500 piaftres was to weigh $2812\frac{1}{2}$ Turkifh drams, fo that a fingle piaftre weighed $5\frac{5}{8}$ drams, or 277 Englifh grains, and the other pieces in proportion. The ftandard of finenefs was reduced at the fame time to 50 carats (or hundredth parts) of fine filver, and 50 of alloy; which gave the value of the piaftre at $19\frac{1}{4}d.$ fterling, and the other filver coins in proportion. But fince that period the Turkifh have fuffered a deterioration. Dr. Kelly, the author of the Univerfal Cambift, has caufed a piaftre of the lateft coinage to be weighed and affayed, by the king's affay-mafter of the mint, and the report is as follows: weight, 8 dwt. 6 gr. Finenefs, 5 oz. 6 dwt. worfe than the Englifh ftandard. This gives its finenefs 47 carats 2 grains Turkifh, and its value in fterling $13\frac{1}{2}d.$ Venetian fequins pafs at prefent for $9\frac{1}{2}$ piaftres; Dutch, Imperial, and Hungarian ducats, for 9 piaftres; Spanifh dollars, and German rix-dollars or Imperial tallaris (called by the Turks cara grouch) for $4\frac{1}{2}$ piaftres.

Damafcus keeps accounts in piaftres of 80 afpers like Aleppo, and has the fame coins as Conftantinople. Smyrna keeps accounts in piaftres or dollars; which the Englifh and Swedes reckon at 80 afpers; the Dutch, French, and Venetians at 100; and the Turks, Greeks, Perfians, and Armenians, at 120 afpers. This piaftre (called by the Turks grouch) is alfo divided into 12 temins, and 40 paras or medini. Tripoli keeps accounts in piaftres, of 13 grimellini, or 52 afpers. The grimellin is valued at 6 fous Tournois, which makes the piaftre of Tripoli worth 3*s.* 3*d.* fterling. At Tunis accounts are kept in piaftres, of 52 afpers; each afper being divided into 12 borbes.

The affay, &c. of the Turkifh piaftres is as follows:

	Affay.	Weight.	Contents in pure Silver.	Value in Sterling.
	oz. dwt.	oz. dwt. grs.	grains.	s. d.
Piaftre of Muftapha III. (1757)	W. 4 11	0 12 7	161	1 $10\frac{1}{2}$
Piaftre of Abdul. Hamed (1773)	W. 5 2	0 12 7	147.5	1 $8\frac{1}{2}$
Another of the fame period -	W. 4 9	0 12 0	159.6	1 $10\frac{1}{4}$
Double piaftre of Selim (1789)	W. 5 12	0 16 $22\frac{1}{4}$	186.4	2 2
Piaftre of Selim (1801) -	W. 5 6	0 8 0	96.7	1 $1\frac{1}{4}$
Half piaftre -	W. 6 13	0 4 1	35.9	0 5
Piaftre of Crim Tartary (1778) -	W. 6 13	0 10 5	91.9	1 $0\frac{3}{4}$
Piaftre of Tunis (1787) -	W. 6 $5\frac{1}{2}$	0 10 0	96.5	1 $1\frac{1}{2}$

N.B. W. denotes worfe than Englifh ftandard.

The piaftre and other filver coins bear the fame infcriptions as the gold coins, and the fame differences exift in them. The infcriptions on the fingle, double, and half piaftres of Selim of 1789 are fimilar to thofe on the fequin fonducli of this prince, which has on one fide, *Sultan Selim, fon of Muftafa Khan*, and on the reverfe, *Struck at Slambul*, in the year 1203, being the date of the Hegira, which began in 622 of the Chriftian era. The piaftre of Tunis bears on one fide the words, *Sultan of the two lands, and fovereign of the two feas, Sultan Selim Khan, bleft with victory:* and on the reverfe, *Struck at Tunis*, in the year, &c. See Kelly's Univerfal Cambift.

Piastre is alfo the French for a *dollar*; which fee.

PIASTRINE. See Pistereen.

PIAT Sopok, in *Geography*, a clufter of five iflands, among

among the Fox iſlands, in the North Pacific ocean. N. lat. 53° 24′. E. long. 189° 46′.

PIATEK, a town of Samogitia; 15 miles N.N.E. of Miedniki.

Piatek, or *Piontek*, or *Prontko*, a town of the duchy of Warſaw, celebrated for its be r; eight miles N.N.E. of Lenczicz.

PIATIA, a town of Naples, in Calabria Ultra; eight miles S.W. of Gierace.

PIATIGER, a town of Ruſſia, in the government of Viatka; 16 miles E. of Kai.

PIATNITZKA, a town of Ruſſia, in the government of Tobolſk; 28 miles N.N.W. of Eniſeiſk.

PIATTA, a town of Italy, in the county of Bormio; two miles S. of Bormio.

PIATTI. See Patti.

PIATZINA, a town of Ruſſia, in the government of Olonetz; 32 miles N.W. of Kargopol.

PIAUBAU, in *Ornithology*. See Muscicapa *Rubricollis*.

PIAVE, in *Geography*, a river which riſes in the Tyroleſe, croſſes the Feltrin and Treviſan, and runs into the Adriatic; 16 miles N.E. of Venice.

PIAVO, a lake of Ruſſia, in the government of Archangel. N. lat. 66° 30′. E. long. 30° 14′.

PIAW, a river of Mexico, which runs into the bay of Honduras, N. lat. 15° 52′. W. long. 85° 50′.

PIAZIDA, a river of Ruſſia, which riſes in lake Piazinſkoi, in the government of Tobolſk, N. lat. 69° 40′. E. long. 89° 14′, and runs into the Kargſkoi ſea, at Verchnei Piazinſkoi. N. lat. 73° 30′. E. long. 87° 14′.

PIAZZA, a town of Naples, in Principato Citra; 14 miles E.N.E. of Salerno.—Alſo, a town of Sicily, in the valley of Noto, ſituated nearly in the centre of the iſland, and containing 18,000 inhabitants; 25 miles N. of Alicata. N. lat. 27° 23′. E. long. 14° 22′.

Piazza, in *Building*, properly called *piache*, an Italian name for a portico, or covered walk, ſupported by arches. The word literally ſignifies a broad open place, or ſquare; whence it alſo became applied to the walks, or porticos around them. See Portico.

PIAZZOLA, in *Geography*, a town of Corſica; 3 miles E.S.E. of La Porta.

PIBERSTAIN, a town of Auſtria; 10 miles W. of Freyſtatt.

PIBGORN, Welſh. See Hornpipe.

PIBIGGA, in *Geography*, a town of Hindooſtan, in Bahar; 35 miles S.W. of Patna.

PIBRAC, a town of France, in the department of the Upper Garonne; 9 miles W. of Toulouſe.

PIC, or Pike, in *Commerce*, a long meaſure in Turkey, which at Aleppo is equal to 299.8 French lines, or $26\frac{2}{3}$ Engliſh inches. At Conſtantinople it is of two ſorts: the longeſt, called Halebi, or Archim, with which ſilks and woollens are meaſured, is 314 French lines, or $27\frac{9}{10}$th Engliſh inches in length; the other, called Endaſſé, with which cotton goods and carpets are meaſured, is 3 per 100 ſhorter. But in the general courſe of European trade the pike is reckoned at $\frac{3}{4}$th of an Engliſh yard. But in different places it is of different lengths. In the iſle of Cyprus the pic or ell meaſures $26\frac{1}{24}$ Engliſh inches. At Damaſcus it is $22\frac{1}{5}$ Engliſh inches. The Morocco pic, or pic Moriſco is $26\frac{1}{3}$ Engliſh inches; ſo that 108 pics = 79 Engliſh yards. The long pic of Algiers is 24.5 Engliſh inches, and the ſhort pic = 18.4 inches. The pic of Candia is 25.1 Engliſh inches; that of Corfu, 22.6; that of Jeruſalem, 27; that of Negropont, 23.4; that of Oran, 27; that of Rhodes, 29.7; the long pic of Scio, 27, and the ſhort, 26; that of Sidon, 23.8; that of Smyrna, 27; that of Tripoli, 27; the woollen pic of Tunis, 26.5; the ſilk ditto, 24.8; and the linen ditto, 18.6 Engliſh inches.

Pic *de l'Etoile, Le*, in *Geography*, a ſmall iſland in the South Pacific ocean, ſo named from its reſemblance in form to a ſugar-loaf, by M. Bougainville in 1768. It is one of the group called by Quiros "Terra Auſtral del Spiritu Santo," by Bougainville "the Archipelago of the Great Cyclades," and by Cook "New Hebrides." S. lat. 14° 29′. E. long. 168° 9′.

Pic *Lamanon*, a mountain on the W. coaſt of the iſland of Saghalien, ſo called by Perouſe. N. lat. 48° 40′.

Pic *Martiniere*, a mountain on the W. coaſt of Saghalien, ſo called by Perouſe, after the name of a French botaniſt, the companion of his voyage, on account of the great number of curious plants found there.

Pic *de Luco*, a town of the duchy of Spoleto; 16 miles S.S.E. of Spoleto.

Pic-*bœuf*, in *Ornithology*. See Buphaga *Africana*.

Pic *de Cayenne, Petit*. See Yunx *Minutiſſima*.

Pic *Noir, &c. &c.* See Picus.

PICA, or Pye, in *Eccleſiaſtical Antiquity*, was a term formerly uſed in the ſame ſenſe with *ordinal*, for a table or directory, pointing out the order in which the devotional ſervices appointed for different occaſions were to be performed. Accordingly ſome derive it from Πι, a contraction of πιναξ, *a table*; and others from *litera picata*, a great black letter at the beginning of ſome new order in the prayer. In much the ſame ſenſe the term was uſed by officers of civil courts, who called their calendars or alphabetical catalogues directing to the names and things contained in the rolls and records of their courts, the *Pyes*.

Pica, in *Geography*, a river of South America, which runs into the Pacific ocean, forming a harbour at its mouth. S. lat. 20° 12′.

Pica *de Regalados*, a town of Portugal, in the province of Entre Duero e Minho; 5 miles N.N.E. of Braga.

Pica, in *Medicine*, called alſo *malacia*, and by the Greeks κιττα, *citta*, ſignifies a depraved ſtate of the appetite, which induces the patient to crave and ſwallow unuſual and indigeſtible things, ſuch as chalk, aſhes, coals, pitch, ſalt, cinders, &c. Why the appellation of *pica* was given to this morbid appetite we know not: ſome writers aſſert that the bird called *pica* (the pic) is ſubject to the diſeaſe.

This morbid longing for uneatable ſubſtances occurs principally in women, and that under two conditions of the uterine ſyſtem; namely, in a ſtate of chloroſis, in the unimpregnated female, and in the early months of pregnancy. The proximate cauſe of the deranged appetite is, doubtleſs, a morbid ſtate of the ſtomach and its ſecreted fluids, which we know to be commonly produced by the ſympathy with the uterus in the early period of pregnancy in general, and to accompany the chlorotic condition. It has been ſuppoſed that the prevalence of an acid in the ſtomach occaſioned this demand for earthy and abſorbent ſubſtances: but many of the ſubſtances, taken in different inſtances, are not poſſeſſed of any antacid qualities. The diſorder is very frequently beyond the power of medicine to relieve in a direct way. In the caſe of pregnancy, it commonly ceaſes altogether about the fourth month, and has been relieved by blood-letting in ſtrong and plethoric women: but in chlorotic girls it is only removed by the courſe of medicine, which removes the morbid ſtate of the habit in general, and reſtores the natural diſcharge where that was ſuſpended. See Chloroſis.

Pica *Naſi*, a name given by Cohauſen to the immoderate taking

taking of ſnuff. It ſeems a whimſical term, but he chooſes to treat this habit as a diſeaſe, and has written an expreſs treatiſe concerning it. The word *pica*, in general, denotes an abſurd and unnatural appetite; and the deſire of taking the powder of tobacco in this manner is called a diſtempered appetite of the part into which it is taken, that is, the noſe.

The conſequences of the taking ſnuff immoderately, are, that the ſenſe of ſmelling is either entirely deſtroyed, or at leaſt greatly impaired: for the nervous tubercles of the noſtrils being continually vellicated by this powder, are by degrees clogged up, or wholly deſtroyed, and the ſenſible membrane, which lines the noſtrils, is rendered callous, and wholly unfit for the diſcharge of its office in ſmelling. The voice is next affected by this powder; for it cauſes a ſort of aſtriction at the bottom of the noſe, which affects the palate, and conſequently the ſpeech; this gives the perſon who takes it a continual deſire of taking more and more, to rid himſelf of that ſtoppage.

Pica, in *Ornithology*, the *Magpie*, a ſpecies of *Corvus*; which ſee.—Alſo, a ſpecies of Alca, the black-billed auk of Pennant and Latham. See Alca.

Pica is alſo a name by which ſome have called the *lanius*, or *butcher-bird*. See Lanius.

Pica *Braſilienſis*. See Merops *Braſilienſis*.

Pica *Glandaria*, the *Jay*. See Corvus *Glandarius*.

Pica *Glandaria cærulea criſtata*, the *Blue Jay*. See Corvus *Criſtatus*.

Pica *Jamaicenſis*. See Gracula *Quiſcala*.

Pica *Maderaſpatana*, &c. of Ray. See Oriolus *Melanocephalus*.

Pica *Marina*, *Puffin*. See Alca *Arctica*.

Pica *Marina*. See Hæmatopus.

Pica *Papuenſis*. See Todus *Paradiſacus*.

Pica *Papuenſis* of Briſſon. See Muscicapa *Paradiſi*.

Pica *Perſica*. See Oriolus *Perſicus*.

Pica, in *Printing*. See Printing.

PICACIA, a name given by the ancients to that diſtempered appetite of women with child, and maidens at a certain time of life, which makes them long for things not fit for food. It is more uſually called *pica*.

PICACUROBA, in *Ornithology*, the name of a Braſilian ſpecies of pigeon, of a greyiſh colour, variegated with a reddiſh-brown, and with very red legs and feet. See Columba *Carolinenſis*.

PICÆ, the ſecond order of the claſs Aves in the Linnæan ſyſtem. The diſtinguiſhing characteriſtics of this order of birds are; a bill ſomewhat compreſſed, more or leſs crooked, and always convex; toes divided, and adapted either for climbing or for ſtepping. Some of them feed on inſects, worms, and the fleſh and offal of other animals, and ſome on the ſeeds and juices of plants. During the breeding ſeaſon they are monogamous, and make their neſts in trees; and during the time that the female is ſitting ſhe is fed by the male. There are twenty-ſix genera, divided into ſections.

A. Feet formed for perching: this ſection contains

Buphaga,	Oriolus,
Certhia,	Paradiſea,
Coracias,	Sitta,
Corvus,	Trochilus,
Glaucopis,	Upupa.
Gracula,	

B. Feet formed for climbing, containing

Bucco,	Pſittacus,
Crotophaga,	Rhamphaſtos,
Cuculus,	Scythrops,
Galbula,	Trogon,
Picus,	Yunx.

C. Feet formed for walking, containing

Alcedo,	Momotus,
Buceros,	Todus.
Merops,	

PICANING, in *Geography*, a town of Africa, on the Ivory coaſt. N. lat. 5° 25′. W. long. 4° 35′.

PICARA, a large province of South America, in New Granada; bounded on the eaſt by the Andes.

PICARD, in our *Old Writers*, a kind of large boat, about fifteen tons or upwards, uſed on the river Severn. Stat. 35 Hen. VIII. cap. 9. 13 Eliz. cap. 11.

Picard, John, in *Biography*, an able French aſtronomer and mathematician in the 17th century, was born at Flêche, in Anjou, but in what year is not known. He was educated for the church, but had a ſtrong thirſt for mathematical knowledge, and for thoſe other branches of ſcience that depend upon it, particularly for aſtronomy. Coming to Paris, his talents ſoon rendered him known and reſpected; and as the Academy of Sciences was at that time forming, he was ſelected to become one of its members, and was aſſociated with them in the year 1666, with the appointment of aſtronomer to the academy. In the ſame year he publiſhed a new micrometer, for meaſuring the ſmalleſt apparent diameters of the ſtars, and their leaſt ſenſible diſtances. In 1671 he was ſent by order of the king to the obſervatory of Uraniberg, on the iſland of Huen, in the Sound, not far from Copenhagen, in order that by aſtronomical obſervations on the ſpot, he might determine, with the greateſt exactneſs poſſible, the true elevation of the pole, and the longitude of that place, for the purpoſe of adapting to the meridian of Paris the aſtronomical tables on the obſervations of Tycho Brahe. He was commiſſioned likewiſe to collect, as far as poſſible, the original manuſcripts of Tycho Brahe's obſervations which had been printed in Germany. He was ſucceſsful in his reſearches, and the MSS. were found to differ in many reſpects from the printed copies, and they contained a book more than had been printed. He traverſed ſeveral parts of the kingdom of France for the purpoſe of meaſuring the degrees of the French meridian, and he firſt gave a chart of the country, which the celebrated Caſſini carried to a great degree of perfection. He was one of the firſt who applied the teleſcope to aſtronomical quadrants; and he was the projector of the work entitled "Connoiſſance des Temps," which he calculated from 1679 to 1683 incluſively. He died in the laſt named year: his chief works are as follow: "A Treatiſe on Levelling;" "Practical Dialling by Calculation;" "Fragments of Dioptrics;" "De Menſuris;" "De Menſura Liquidorum et Aridorum;" "An Abridgment of the Meaſure of the Earth;" "A Journey to Uraniberg, or Aſtronomical Obſervations made in Denmark." Theſe and other of his pieces are to be found in the 7th and 8th vols. of the Memoirs of the Academy of Sciences. Moreri.

PICARDS, in *Eccleſiaſtical Hiſtory*, a religious ſect, which aroſe in Bohemia in the 15th century, ſo called from its author, who, becauſe he originally came from Picardy, was called *Picard*. He drew after him, as it has been ſaid, a great a great number of men and women, pretending he would restore them to the primitive state of innocence in which Adam was created: and accordingly himself assumed the title of the New Adam.

Under this pretence (say their enemies) he taught his followers to abandon themselves to all impurity; making them believe, that in this consisted the liberty of the sons of God; and that all those not of their sect were in bondage.

He first began in Germany and the Low Countries, persuading many people to go naked, and giving them the name of Adamites. After this, seizing an island in the river Lausnecz, a few leagues from Thabor, the head quarters of Zisca, he fixed himself and his followers therein; appointing his women to be common, but allowed none to enjoy them without his permission: so that when any man desired a woman, he carried her to Picard, who gave him leave in these words, "Go, increase, multiply, and fill the earth."

At length Zisca, the great general of the Hussites, (so famous for his victories over the emperor Sigismund), struck with their abomination, marched against them; and, making himself master of their island, put them all to death except two; whom he spared to inform himself of their doctrine.

Such is the erroneous and injurious account, as many have thought, which different writers, ultimately relying on the insufficient authorities of Æneas Sylvius and Varillas, have given of the Picards, who seem to have been a party of the Vaudois, or Waldenses, that fled from persecution in their own country, and sought refuge, about the beginning of the 15th century, in Bohemia. It is very doubtful whether a sect of this denomination, chargeable with the licentious principles and conduct above recited, ever existed; and we cannot forbear expressing our astonishment that Mr. Bayle, in his art. *Picards*, should adopt the reproachful representations of the writers just mentioned.

It is most probable, as competent and candid judges have maintained, that the whole or a great part of these charges is either an exaggeration or a calumny invented and propagated, in order to disgrace the Picards, because they deserted the communion and protested against the errors of the church of Rome. Lasitius relates, that Picard settled in Bohemia in the year 1418, accompanied by forty other persons, besides women and children. The Jesuit Balbinus, in his Epitome Rerum Bohemicarum, lib. ii. concurs in this account, and charges on the Picards none of the extravagancies or crimes ascribed to them by Sylvius. Schlecta, secretary of Ladislaus, king of Bohemia, in his letters to Erasmus, gives a particular account of the Picards; representing them as persons, who considered the pope, cardinals, and bishops of Rome, as the true Antichrists; who censured those that adored the consecrated elements in the eucharist as idolaters, and denied the corporal presence of Christ in this ordinance; who condemned the worship of saints, prayers for the dead, auricular confession, the penance imposed by priests, the feasts and vigils observed in the Romish church; and confined themselves to the observance of the sabbath, and of the two great feasts of Christmas and Pentecost. From this abstract of their sentiments, it sufficiently appears, that they were no other than the Vaudois; and M. de Beausobre has plainly shewn that they were both of the same sect under different denominations. Besides, it is a certain fact, that the Vaudois were settled in Bohemia in the year 1178, where some of them adopted the rites of the Greek church, and others those of the Latin church. The former were generally adhered to till about the middle of the fourteenth century, when the establishment of the Latin rites occasioned great disturbance. When the national troubles commenced in Bohemia, on occasion of the opposition to the papal power (see MORAVIANS), the Picards appeared more publicly in the avowal and defence of their religious opinions; and they formed a considerable body in an island by the river Launitz or Lausnecz, in the district of Bechin, and recurring to arms, were defeated by Zisca. Encyclop. art. *Picards*.

Mosheim considers the Picards as deriving their name from that of the *Beghards* (see that article), by a change in the pronunciation of that word, and concurs in the unfavourable account of them given by the writers to whom we have already referred. He represents them as appearing in the religious assemblies, and joining in the celebration of divine worship, without any veil or covering whatever; agreeably to the maxim which they are said to have adopted, *viz.* that those were not free (*i. e.* sufficiently extricated from the shackles of the body) who made use of garments, particularly such garments as covered the thighs and the parts adjacent. But though he mentions this practice, and denominates them an absurd sect, which by such tenets incurred deserved reproach, he acknowledges that in their religious assemblies nothing passed that was contrary to the rules of virtue, however they were suspected of the most scandalous incontinence, and of the most lascivious practices. He states that Zisca, the austere general of the Hussites, gave credit to the rumours that were industriously circulated against them; and falling upon them in the year 1421, put some to the sword, and condemned the rest to the flames, which dreadful punishment they sustained with the most cheerful fortitude, and also with a contempt of death that was peculiar to their sect, and which they possessed in a degree that seems to surpass credibility. These extravagant enthusiasts, he says, were distinguished by other appellations, such as those of *Adamites* and *Beghards* (see these articles), and the denomination was extended so as to comprehend the Hussites, and all the Bohemians who opposed the tyranny of the church of Rome. They were called by their enemies, and indeed by the multitude in general, "Picardiers." He says that Beausobre, in his attempts to justify the Picards, or Bohemian Adamites, against the accusations of their enemies, which he considers as altogether groundless, is manifestly endeavouring to wash the Ethiopian white: and he adds, that it may be demonstrated, by the most unexceptionable and authentic records, that his account is true; suggesting at the same time a charge of prejudice and partiality against the respectable and learned author from whom he differs. Eccl. Hist. vol. ii. p. 464, note.

PICARDY, in *Geography*, a considerable province of France before the revolution, which now forms the departments of the Somme, part of the department of the straits of Calais, and the department of the Aisne; which see respectively.

PICARY, in *Zoology*, a name given by Bancroft, in his "Guiana," to the SUS *Tajassu*; which see.

PICATUM VINUM. See VINUM.

PICAUVILLE, in *Geography*, a town of France, in the department of the Channel; 9 miles N.W. of Charentan.

PICAWEES, Indians of America, on the banks of the Great Miami.

PICCINI, NICOLA, in *Biography*, born in 1728 at Bari, capital of the little province of that name, in the

kingdom

kingdom of Naples, may be ranked among the moſt fertile, ſpirited, and original compoſers that the Neapolitan ſchool has produced. An invincible paſſion for muſic fruſtrated the intention of his father, who deſigned him for the church, and made him ſtudy for that intent; but for fear of his neglecting ſerious buſineſs for amuſement, he would not let him learn muſic. The young man, whoſe genius ſuffered him not to reſt, never ſaw an inſtrument, eſpecially a harpſichord, without emotion; he practiſed in ſecret all the opera airs which he had heard, and which he retained with ſurpriſing accuracy. His father having carried him one day to the biſhop of Bari, he amuſed himſelf in the room where he was left alone, with a harpſichord which he found there, thinking he could be heard by no one; but the prelate in the next apartment having heard him, condeſcended to go to the harpſichord, and obliged him to repeat many of the airs which he had been playing; this he did with ſo much accuracy and preciſion, with the ritornele and accompaniments, which he likewiſe remembered, that the biſhop perſuaded his father to ſend him to the Conſervatorio of St. Onofrio, at Naples, of which the celebrated Leo was then the principal maſter.

The young Piccini was admitted in that ſeminary in 1742, and was placed at firſt under the tuition of a ſubaltern maſter, whoſe leſſons, given in a dry and contracted manner, ſoon diſguſted him: and in a few months his diſcontent at ſuch unprofitable inſtructions drew on him the reſentment of his tutor, expreſſed in no very gentle way. Shocked with this treatment, he reſolved to ſtudy by himſelf, and began compoſing without rules, or any other guides than his own genius and fancy, pſalms, oratorios, and opera airs; which ſoon excited the envy or admiration of all his fellow ſtudents. He even had the courage to compoſe an entire maſs. One of the maſters who had ſeen it, and even permitted him to have it rehearſed, thought it right to mention it to Leo; who, a few days after, ſent for Piccini to come and ſpeak to him. The young man, penetrated with the higheſt reſpect for ſo great a maſter, which is in ſome ſort an intuitive indication of genius, was extremely frightened at this meſſage, and obeyed the order with fear and trembling. "You have compoſed a maſs," ſaid Leo, with a cold, and almoſt ſevere countenance: "Yes, ſir." "Shew me your ſcore;"—"ſir, ſir,"—"ſhew it me, I ſay." Piccini thought himſelf ruined; but he muſt obey. He fetched his ſcore, at which Leo looked, turned over the leaves, examined each movement, ſmiled, rung the bell, as the ſignal for a rehearſal. The young compoſer, more dead than alive, begged in vain to be ſpared what he thought ſuch an *affront*. The ſingers and inſtrumental performers obeyed the ſummons; the parts were diſtributed, and the performers waited only for Leo to beat the time. When turning gravely to Piccini, he preſented him the *bâton*, which was then uſed every where in the performance of full pieces. Piccini, put to new confuſion, offered freſh prayers to be excuſed obeying this command, wiſhing he had never dared to meddle with compoſition. At length he muſtered his courage, and marked with a trembling hand the firſt bars. But ſoon animated and inflamed by the harmony, he neither ſaw Leo, nor the ſtanders by, who were numerous; he was abſorbed in his muſic, and directed its performance with a fire, energy, and accuracy which aſtoniſhed the whole audience, and acquired him great applauſe. Leo kept a profound ſilence during the performance: when it was over, —"I forgive you, for once," ſaid he, "but if you are again guilty of ſuch preſumption, you ſhall be puniſhed in ſuch a manner as you will remember as long as you live. What! you have received from nature ſo eſtimable a diſpoſition for ſtudy, and you loſe all the advantages of ſo precious a gift! Inſtead of ſtudying the principles of the art, you give way to all the wild vagaries of your imagination, and fancy you have produced a maſter-piece." The boy, piqued by theſe reproaches, related what had paſſed between him and the aſſiſtant maſter under whom he was placed. Leo became calm, and even embraced and careſſed him; ordering him to come to his apartments every morning, to receive inſtructions from himſelf.

This truly great maſter died ſuddenly ſome months after. Happily for his promiſing pupil, his ſucceſſor was the celebrated Durante, one of the moſt learned compoſers Italy ever produced. He ſoon diſtinguiſhed Piccini from the reſt of his claſs; conceived a particular affection for him; and had pleaſure in communicating to him all the ſecrets of his art. "Others are my pupils," he ſometimes uſed to ſay, "but this is my ſon."

At length, after twelve years' ſtudy, Piccini, in 1754, quitted the Conſervatorio, knowing all that is permitted to an individual to know in practical muſic, and poſſeſſed of ſuch a creative and ardent imagination, as perhaps, till then, was unexampled.

He begun his career at the Florentine theatre in Naples, which is that of San Carlo, what Foote's theatre uſed to be compared with Drury Lane, or the Opera Houſe. His firſt production there was "Le Donne Diſpettoſe," and the next year, "Le Geloſie," and "Il Curioſo del ſuo Proprio Danno," of all which the ſucceſs increaſed in a duplicate ratio. At length, in 1756, he ſet the ſerious opera of "Zenobia" for the great theatre of San Carlo, which was crowned with ſtill greater ſucceſs than his comic operas. In 1758, he compoſed "Aleſſandro nell' Indie," for Rome; and after this, every theatre in Italy was eager to engage him. In 1760, his celebrated comic opera of the "Buona Figliuolo" had a ſucceſs that no muſical drama could boaſt before. It was no ſooner heard at Rome than copies were multiplied, and there was no muſical theatre in Europe where this burletta was not frequently performed, in ſome language or other, during many years. In 1761, he compoſed ſix operas, three ſerious and three comic, for different theatres of Italy; and was at once applauded in Turin, Reggio, Bologna, Venice, Rome, and Naples. Sacchini aſſured us, in 1776, that Piccini had compoſed at leaſt three hundred operas, thirteen of which were produced in ſeven months. On his arrival at Paris, he received many mortifications before his reputation was firmly eſtabliſhed, from the partizans of the old French muſic, as well as the friends of Gluck. The ſucceſs of his operas of "Roland," "Atys," "Iphigénie en Tauride," "Adele de Ponthieu," "Didon," "Diane et Endymion," and "Penelope," ſeems to have ſolved a problem which was long thought inſolvable: "Whether the French language was capable of receiving Italian melody?"

If we add to ſo many dramatic works the oratorios, maſſes, cantatas, and occaſional ſongs and ſcenes in paſticcio operas, it would prove, that in twenty-five years he had produced more muſic, and good muſic, than any other ten maſters had done in their whole lives.

What ſtill more aſtoniſhes in ſuch innumerable works, is the prodigious variety which reigns in them all; and the ſcience which never degenerates into pedantry or affectation; an harmony pure, clear, and profound; a melody perfectly ſuited to the ſubject and ſituation of the performers; and a force, an originality, and reſources of all kinds, unknown till his time, and of which perhaps the ſecret will long remain undiſcovered. And what appears as extraordinary as the reſt is, that the genius of this maſter, far from being exhauſted by ſo many labours, by frequent and ſevere ſickneſs, by domeſtic diſquietude and chagrin, inſeparable from a numerous family, ſeemed, before the revolution, to continue in full force. Deprived of all his appointments, and well-earned theatrical penſions, he returned to Naples, where, after he had eſtabliſhed himſelf in France, all his appointments had been diſpoſed of. Unluckily, on the arrival of a French army at Naples, he either did adhere to the invaders, or was ſuppoſed by the court to be in correſpondence with them, which occaſioned his diſgrace, and precipitated his flight back to Paris, where he was received with open arms, and placed at the head of a new ſinging ſchool; but we have heard nothing of new compoſitions after his return, nor any thing more concerning him, except that he died at Paris in 1800.

PICCINİNI, Alessandro, of Bologna, lived about the year 1570, and was in the ſervice of the duke of Ferrara in 1594. He is author of a treatiſe on the tablature of the lute, which was in great eſtimation. In this work, we find the origin of the *theorbo* and *pandore.* He pretends to have been the inventor of the *arch-lute.*

PICCIOLO, in *Commerce*, a money of account in the iſland of Sicily. Thus, a taro contains 2 carlini, 15 ponti, or 120 piccioli; a carlino, 10 grani; a ponto, 8 piccioli; and a grano, 6 piccioli.

PICCITONO, Parde Angelo da, in *Biography*, author of a book entitled "Fior Angelico di Muſica," publiſhed at Venice in 1547; a work which, however difficult to find at preſent, is, from its dulneſs and pedantry, ſtill more difficult to read.

PICCOLOMINI, Alessandro, a learned Italian, was born at Sienna in 1508. He paſſed the early part of his life in his native place, and was a member of the celebrated academy of Degli Intronati, in which he bore the name of "Stordito." He is ſuppoſed to have been in that city at the time of the viſit of the emperor Charles V. in 1536, when his comedy, entitled "Amor Coſtante," was recited before that prince. He wrote two other comedies, "L'Aleſſandro" and "L'Ortenſio," and tranſlated the 13th book of Ovid's Metamorphoſis, and the 6th book of Virgil's Eneid, into Italian verſe, and printed a collection of 100 ſonnets. About the year 1540 he went to Padua, where he was aggregated to the academy Degli Infiammati, and engaged to read lectures in it on moral philoſophy. He wrote books alſo on morals, on philoſophy, and aſtronomy; and by order of duke Franceſco de Medici, he wrote a book on the reformation of the calendar undertaken by pope Gregory XIII. He reſided ſeveral years at Padua and Rome, and at an advanced age retired to Sienna, where he poſſeſſed a villa and a fine garden. In 1574 Gregory nominated him to the titular archbiſhopric of Patras, and made him coadjutor of the archbiſhop of Sienna. He died in 1578, and was interred in the cathedral of that city.

PICE, in *Commerce*, a money of account and copper coin in the Eaſt Indies. At Calcutta and in Bengal, 12 pice = 1 anna, and 16 annas = 1 current rupee. See Rupee.

The double and ſingle pice are copper coins, with a mixture of tin or lead at Bombay, the ſingle pice being 4 reas, and the double pice or fuddea being 8 reas, the rea being $\frac{1}{100}$dth of the quarter, and the quarter $\frac{1}{4}$th of the rupee. At Anjengo, on the Malabar coaſt, accounts are kept in fanams, pice, and budgerooks: a fanam being = 12 pice, or 16 vis, and 1 pice = 4 budgerooks: a ſilver rupee is worth 7 old fanams, or 6 new ones, called gallon fanams. All theſe are real coins. At Scindy the coins are ſilver rupees of 16 annas or 48 copper pice. At Surat, accounts are kept in rupees of 16 annas or 64 pice. Here are alſo pezas or pice of copper or lead, 64 of which are reckoned to 1 ſilver rupee. Sixty padens, a ſort of bitter almonds from Perſia, paſs for 1 pice.

Pice is alſo a weight in the Eaſt Indies. See Maund.

PICENDACA, in *Ancient Geography*, a town of India, in the interior of the country belonging to the people called Arvari. Ptolemy.

PICENTES, a people of Italy, inhabitants of Picenum, who were originally Sabines. Strabo ſays that they took their name from the word *picus*, which they followed whilſt they were going to eſtabliſh themſelves in their new country. See Picenum.

PICENTIA, Bicenza, a town of Italy, and capital of the Picentini. It was ſituated in the interior of the country: and Pliny reports, that the inhabitants were driven from it on account of their having taken part with Hannibal. It continues to ſubſiſt under the ſame name; though at preſent there are merely traces of it remaining.

PICENTINI, a people of Italy, who were deſcended from the Picentes, and whoſe immediate origin is very uncertain; they were ſettled towards the weſt on the ſea-coaſt.

PICENTINUM, Pezentinum, or *Peſcentinum*, a town of Pannonia, upon the route from Æmona to Sirmium, between Inicerum and Leuconum, according to Antonine's Itinerary.

PICENUM, a country of Italy, on the Adriatic gulf; extending from the Æſis, towards the N.W., as far as Truentus. It was bounded to the N. by the Æſis, to the S. by the Truentus, to the E. by the Adriatic ſea, to the W. by a ſmall part of Umbria and mount Fiſcelus, and ſome other mountains which ſeparated it from the country of the Sabines. Its principal rivers were the Æſis, the Miſios, the Potentia, the Tinna, and the Truentus. The moſt noted places were, commencing from the N., Ancona, Auximum, Firmum, and Aſculum. The origin of its name has been given under Picentes. Euſebius and Servius, however, give the name of Picus to the chief of the colony.

PICHANA, in *Geography*, a town of South America, in the province of Cordova; 130 miles N.W. of Cordova.

PICHINCA, a mountain of Peru, in the juriſdiction of Piura, and biſhopric of Truxillo, whoſe height is ſaid to be 2432 toiſes above the level of the ſea. M. Von Humboldt was twice at the mouth of the crater of this mountain; no one but Condamine having ever reached it before. From the edge of the crater, he ſays, riſe three peaks, which are free from ſnow, as it is continually melted by the aſcending vapour. At the ſummit of theſe is a rock that projects over the precipice, and from which he made his obſervations. The rock is about twelve feet long by ſix broad, and ſtrongly agitated by frequent ſhocks, of which he counted eighteen in leſs than half an hour. On this he lay on his belly, that he might the better examine the bottom of the crater. The mouth of the volcano forms a circular hole, near a league in circumference, the perpendicular edges of which are covered with ſnow on the top. The inſide is of a deep black; but the abyſs is ſo vaſt, that the ſummits of ſeveral mountains may be diſtinguiſhed in it. Their tops ſeemed to be ſix hundred yards below his ſtation; and he has no doubt but the bottom of the crater is on a level with the city of Quito, which the mountain overlooks. Condamine found it extinct, and even covered with ſnow: but M. Humboldt found it burning. On his ſecond viſit, being furniſhed with inſtruments, he found the diameter of the crater to be 1600 yards, whereas that of

Vesuvius is but 670. The height of the mountain is 5280 yards.

PICHINCHAS, a town of South America, in the province of Quito; 15 miles N.E. of Quito.

PICHMANSKOI, a town of Ruſſia, in the government of Olonetz, on the lake Latcha; 32 miles S.S.W. of Kargapol.

PICICITLI, in *Ornithology*, the name of a bird in the Spaniſh Weſt Indies, deſcribed by Nieremberg. Its head and neck are black, and its whole body grey; it is a ſmall bird, and makes its appearance in Mexico after the rainy ſeaſons; it is a bird of paſſage, and it is not known where it breeds. See PIPRA *Criſtata*.

PICIERNO, in *Geography*, a town of Naples, in the province of Baſilicata; eight miles W.N.W. of Potenza.

PICIOTTI, a river of Naples, which runs into the ſea, 15 miles S.E. of Reggio.

PICK, a river of Upper Canada, which runs into lake Superior, N. lat. 48° 28′. W. long. 86° 4′.—Alſo, a ſmall iſland, in the N. part of lake Superior. N. lat. 48° 31′. W. long. 86° 28′.

PICK, among *Miners*, is a tool which they uſe to cut down the clifts and rocks of ſtone to make paſſages in the earth; and which is alſo uſed in digging canals.

PICK-*Axe*, in the *Military Art*, a tool carried by the pioneers to dig up ground that is too hard for the ſpade; they are of great uſe for mending the ways, and in fortifications.

PICKS, *Ear*. See EAR-*picks*.

PICKAGE, or PICCAGE, *Piccagium*, an ancient cuſtom, or duty, paid at fairs and markets, for breaking the ground, and pitching up ſtalls, or ſtandings.

This profit of pickage was uſually given, or granted, in charters for holding a fair or market.

PICKAWAY, in *Geography*, a county in the ſtate of Ohio, containing, in 1810, 10 towns and 7124 inhabitants. —Alſo, a town in the ſaid county, of the ſame name, containing 1598 inhabitants.

PICKEERING, or PICKEROONING. See PICQUEERING.

PICKER, or HORSE-PICKER, in the *Manege*, an iron inſtrument five or ſix inches long, bent or crooked on one ſide, and flat and pointed on the other. It is uſed by grooms to cleanſe the inſide of the horſes feet, and to pick out the earth, ſand, or ſmall ſtones that get into them.

PICKERELL, in *Ichthyology*, an Engliſh name uſed by ſome authors for the jack or pike.

PICKERING, in *Geography*, a market-town in the weſt diviſion of the wapentake of Pickering-Lythe, and North Riding of Yorkſhire, England, is pleaſantly ſeated on an eminence, ſurrounded by the lofty mountains of Blakemore, at the diſtance of 26 miles from York, and 225 from London. It is a town of very remote antiquity. It ſeems formerly to have enjoyed the privileges of a borough, and undoubtedly ſent members more than once to parliament. How it loſt this right is unknown; but it was moſt probably through neglect. The market day here is on Monday weekly; and there are beſides four annual fairs for horned cattle, horſes, and ſheep. Pickering is an honour belonging to the duchy of Lancaſter, and poſſeſſes a juriſdiction over ſeveral of the neighbouring villages, lying within its boundaries. Here are, therefore, held the courts of the honour, and alſo the petty ſeſſions for the weſt diviſion of the wapentake.

In the parliamentary returns of 1811, the houſes in this town are eſtimated at 540 in number, and the inhabitants at 2332. The former are arranged chiefly in one long ſtraggling ſtreet, which offers no edifice worthy of notice, except the church, an ancient and ſpacious ſtructure, adorned with a lofty ſpire. Here are three meeting-houſes appropriated to the public worſhip of Quakers, Preſbyterians, and Methodiſts. Its weſtern extremity, however, is rendered intereſting by the remains of a ſtrong caſtle, which occupies the brow of a hill overlooking the town, and commanding a delightful view of the vale of Pickering. The date of the foundation of this fortreſs is uncertain, but it appears from Domeſday book to have belonged to Morcar, earl of Northumberland, in the time of Edward the Confeſſor. In the beginning of the reign of Henry III. the cuſtody of it was committed to William, lord Dacre, high ſheriff of the county; but this nobleman had only retained it two or three years, when it was beſtowed by the monarch on his own ſon, Edmund, earl of Lancaſter, whoſe ſucceſſor, Thomas, forfeited it to the crown by rebellion. His deſcendants, however, afterwards recovered it; and it conſequently came by marriage into the poſſeſſion of the celebrated John of Gaunt, duke of Lancaſter and king of Caſtile. What became of it after his death is unknown; but in the reign of queen Elizabeth we find it once more poſſeſſed by the crown; and in the time of the civil wars, in the ſeventeenth century, it is recorded to have ſtood a long ſiege againſt a party of the parliamentary forces ſent to reduce it. Beauties of England and Wales, vol. xvi., by John Bigland.

PICKERING, a townſhip in the Eaſt Riding of the county of York, in Upper Canada, between Whitby and Scarborough, and parting lake Ontario.

PICKERSGILL COVE, a harbour within Chriſtmas Sound, on the S. coaſt of Terra del Fuego, at the S. extremity of South America.

PICKERSGILL *Harbour*, a port of New Zealand, on the S. ſhore of Duſky bay. S. lat. 45° 47′. E. long. 166° 18′.

PICKERSGILL *Iſland*, a ſmall iſland in the South Atlantic ſea, near the S. coaſt of the iſland of Georgia, ſo called after the name of captain Cook's third lieutenant. S. lat. 54° 47′. W. long. 36° 42′.

PICKERSVILLE, the chief town of Waſhington diſtrict, in South Carolina; 771 miles from Philadelphia.

PICKET, PICQUET, or *Piquet*, in *Fortification*, a ſtake ſharp at one end, and uſually ſhod with iron; uſed in laying out the ground, to mark the ſeveral meaſures and angles thereof.

There are alſo larger pickets, driven into the earth to hold together faſcines, or faggots, in any work caſt up in haſte.

PICKETS are alſo ſtakes driven into the ground by the tents of the horſe, in camp, to tie their horſes to; and before the tents of the foot, where they reſt their muſkets, or pikes about them, in a ring.

The picket was a corporal puniſhment, chiefly uſed by the cavalry and artillery, and in the former often inflicted by order of the commanding officer, without the ſentence of a court-martial. The mode of inflicting it was this: a long poſt being driven into the ground, the delinquent was ordered to mount a ſtool near it, when his right hand was faſtened to a hook in the poſt by a nooſe round his wriſt, drawn up as high as it could be ſtretched; a ſtump, of the height of the ſtool, with its end cut to a round and blunt point, was then driven into the ground near the poſt before-mentioned, and the ſtool being taken away, the bare heel of the ſufferer was made to reſt upon the ſtump, which, though it did not break the ſkin, put him to great torture: the only mitigation he could obtain was by reſting his weight on his wriſt, the pain of which ſoon became intolerable. Soldiers were frequently ſentenced to ſtand on the picket for

for a quarter of an hour. This, like the riding of the wooden horſe, has been for ſome time left off, as it lamed and ruptured many ſoldiers. See *Wooden* Horse.

Pickets are alſo ſtakes with notches toward the top, to which are faſtened the cordages of tents. Thus, to plant the picket, is to encamp.

Picket, in *Gaming*. See Picquet.

Picket, *Watching*, in *Ornithology*. See Oriolus *Nidipendulus*.

PICKLE, a brine, or liquor, ordinarily compoſed of ſalt, vinegar, &c. ſometimes with the addition of ſpices; in which meats, fruits, and other things, are preſerved and ſeaſoned.

Pickle is alſo uſed ſubſtantively, for a fruit, root, leaf, or other vegetable matter, prepared in pickle, to be uſed by way of ſauce, &c. See Sallet, &c.

They pickle artichoaks, muſhrooms, aſhen-keys, barberries, aſparagus, beans, onions, &c. Broom-buds, capers, and olives, are pickled with oil and vinegar.

Pickle, in *Agriculture*, a ſort of brine or liquor uſed for ſteeping grain, to preſerve it from diſeaſe, ſlugs, and vermin.

A great number of different compoſitions have been at different times employed as ſteeps or pickles, for freeing grain from diſeaſe; but thoſe which are the moſt in uſe at preſent are ſuch as are deſcribed below, though very ſtrong ſolutions of common ſalt, and other ſimilar ſubſtances, have been often employed.

Pickle Arſenic.—Much advantage is ſaid to have been found by Mr. Young, from the uſe of half a hogſhead of ſtrong lixivium of wood-aſhes, put in a caſt-iron boiler, with ſeven pounds of common ſalt, and one pound of arſenic boiled well, and kept in the boiler for uſe when cold. And which, without the ſalt, was employed with benefit by Mr. Andrews.

Pickle Salt.—This is prepared, according to Mr. Summerville, ſometimes with plain water, into which common kitchen ſalt is put, till it is of ſuch a ſtrength as to float an egg. In many caſes, however, ſea-water is uſed, and ſalt added to it, till it will alſo carry an egg. The advantage of uſing ſea-water is, that leſs ſalt is required. The pickle, thus prepared, is put into a large open veſſel, that will hold perhaps 30 or 40 gallons: the wheat is then poured into it, in the quantity of from a buſhel, to two buſhels at a time, and well ſtirred round, either with a broom or a ſtick; during the ſtirring, the light grains riſe to the ſurface and are ſkimmed off; the veſſel is then lifted up, and the contents poured into another of equal dimenſions, upon the mouth of which a ſieve is placed; the ſieve retains the grain, and ſuffers the pickle to paſs through it into the veſſel beneath. The ſame quantity of wheat is again put into the pickle, and the ſame proceſs repeated, till the whole has been waſhed and pickled; and progreſſively as it is taken out of the water, ſome new ſlaked lime is ſifted upon it. The whole is then carefully mixed up with a wooden ſhovel, and frequently turned over, till it attain a ſufficient degree of dryneſs, in which ſtate it is committed to the earth without any further preparation or management.

Pickle Urine.—This is prepared in this way, according to the ſame writer: a quantity of urine, in as ſtale a ſtate as poſſible, is put into a veſſel, in the ſame manner as for the ſalt pickle, into which the grain is put and well ſtirred. The contents are then poured through a ſieve, and the proceſs continued till the whole of the wheat intended to be ſown is moiſtened. It is then ſprinkled with lime, as in the former caſe, and committed to the earth. It is, however, added, that in many caſes, inſtead of mixing the whole of the grain with the urine, it is common to ſpread the wheat upon the barn-floor, and ſprinkle the urine upon it, either with a watering-pan or a kind of bruſh made of ſtraw: when it is ſufficiently moiſtened, lime is made uſe of as before, and the grain ſown.

Pickle Italian.—This is that recommended by J. B. Scandella, an Italian phyſician, which is prepared in this manner: Take of nitre, three pounds; alum, one pound; vitriol, ſix ounces; verdigris, three ounces; wood-aſhes, well ſifted, ſix pounds; boil the whole in a copper with five pails of water for an hour, then remove them from the fire, and pour them into a large veſſel; then add ſixteen pails of water, in which half a buſhel of quick-lime has been previouſly diſſolved; mix the whole intimately, and allow them to ſtand ſtill till they are quite cold. In this ſteep, two buſhels and a half of wheat are to be plunged, and left for about ſix hours, ſtirring it up frequently with a wooden ſhovel, and ſkimming off what riſes to the ſurface: the wheat is then to be withdrawn, and ſpread out till it is dry enough for ſowing. The proceſs is thus to be continued until the whole quantity of ſeed intended to be ſown is pickled. The above ſteep is generally ſufficient for preparing about twenty-four buſhels of wheat.

And on theſe different pickles or ſteeps the ingenious writer has made ſeveral pertinent reflections. On the firſt he remarks, that as far as his own obſervation, aided by the teſtimony of the moſt reſpectable farmers, can be depended upon, it has never been known to fail in a ſingle inſtance, where judiciouſly applied; that is to ſay, it has always prevented the crop from ſuffering by ſmut. But though it has anſwered this purpoſe moſt effectually, and the proofs in favour of it are too numerous to be diſputed, there is little doubt that, under certain circumſtances, it may be highly injurious to the crop. And that while the grain, ſteeped in this pickle, continues in a moiſt ſtate, it may be kept for any length of time, without much injury to its vegetative powers; a circumſtance of no ſmall conſequence, as it not unfrequently happens that after the grain has been pickled, and made ready for ſowing, a ſudden fall of rain prevents it from being put into the earth for ſeveral days, perhaps weeks. But though the pickle is thus harmleſs while the grain continues in a moiſt ſtate, repeated trials convince him that it is quite otherwiſe when well dried, and expoſed to a certain degree of heat. He does not hazard this merely as an opinion, but ſpeaks from conviction, when he ſays that if wheat, which has undergone this preparation, and has had lime in a very active ſtate mixed with it, is ſown early in the autumn (as in Auguſt), upon dry warm land, and no rain falls for a conſiderable time after, a thing by no means uncommon at that ſeaſon of the year, a great proportion of the grain will either be entirely deſtroyed, or materially injured, by the dry cauſtic cruſt with which it is ſurrounded. The miſchief in this caſe is certainly done by the action of the lime, and in many inſtances is, he ſuppoſes, very conſiderable. But in order to avoid this inconvenience, the writer ſtates, that from much inquiry, as well as numerous trials of his own, he is perfectly ſatisfied that the moſt valuable part of this preparation conſiſts in immerſing the wheat in the brine, and that the lime is only added afterwards as an abſorbent to dry up the ſuperfluous part of the moiſture, and make the grains ſeparate, and ſow more readily. If this is admitted, and it certainly is the caſe, it will be extremely eaſy to reap the whole benefit of the ſalt pickle, without any of its defects, merely by ſubſtituting ſome other article in the place of lime; and for that purpoſe nothing ſeems better calculated than powdered chalk, or common whitening. The former is known, in its unburnt ſtate,

ſtate, to be entirely deſtitute of any cauſtic or corroſive quality; and the latter conſiſts of burnt limeſtone, which has been completely ſaturated with moiſture, and afterwards dried, by which proceſs its activity is deſtroyed. Both of theſe articles can be obtained in ſufficient quantity, in moſt ſituations; and as neither of them are expenſive, they will be found good ſubſtitutes for lime; and if properly managed, will anſwer every purpoſe that can be expected from it, without the ſmalleſt degree of riſk.

It is aſſerted, in reſpect to the urine pickle, that there is no article at preſent employed that requires to be uſed with more circumſpection than this; nor is there any where the riſk or loſs attending its uſe has a chance of being ſo great. He is ready to admit, that where the urine is ſufficiently ſtale, and the grain properly moiſtened with it, every inſect or animalcule contained therein will be completely deſtroyed; but to counterbalance this, he has to ſtate that as yet there has been no teſt eſtabliſhed to aſcertain the neceſſary degree of ſtaleneſs: and as it is known that urine, which is not ſtale, will not deſtroy vermin, there is an abſolute certainty, if it is uſed in that ſtate, it will be of no ſervice; and that, on the other hand, when urine is completely ſtale, it abounds with volatile alkali, which, in its naked ſtate, is known to be hurtful, when applied either to ſeeds or plants; but when united with lime, it then forms what is called cauſtic alkali, in which ſtate its ſtrength and dangerous qualities are very conſiderably increaſed. This compound, though an excellent manure when applied to the ſoil, and allowed to operate properly upon it before the crop is ſown, is completely deſtructive both to ſeeds and plants, when brought into contact with them. When wheat, therefore, has been completely moiſtened with urine, and is afterwards mixed with quick-lime, the cruſt with which it is ſurrounded will be of the moſt acrid nature, and nothing but throwing the ſeed immediately into a tolerably moiſt ſoil can poſſibly ſave it from deſtruction. Accordingly it has often happened, when wheat pickled in this way has, by bad weather, or any other accident, been prevented from being ſown even for a ſingle night, nine-tenths of the ſeed have been known to periſh. He has ſaid, that nothing can ſave the ſeed thus cruſted over from deſtruction, but ſowing it inſtantly upon land containing a certain ſhare of moiſture. If the ſoil happens, however, to be of a warm nature, is very dry at the time of ſowing, and the weather continue warm and dry for any conſiderable time afterwards, an immenſe deal of the ſeed will periſh by the action of the pickle. And theſe objections to the urine pickle, which every man who is in the ſlighteſt degree acquainted with its chemical properties will readily underſtand, apply to thoſe caſes where the pickle has been moſt faithfully prepared and adminiſtered, and that is when the grain has been completely immerſed in it. The other method, *viz.* that of laying the wheat upon the barn-floor, and ſprinkling it with a wiſp of ſtraw dipt in the urine, is alſo liable to many objections. He has already hinted, that we have at preſent no teſt for aſcertaining the neceſſary degree of ſtaleneſs in urine: the want of this muſt always ſubject the uſe of it to very great uncertainty. But admitting that it were in all caſes ſufficiently ſtale, there is no poſſibility of applying it properly or equally, when the wheat is ſpread upon the floor: ſome of it will have more moiſture than it requires, ſome will be very imperfectly moiſtened, and many of the grains will not be moiſtened at all. He need ſcarcely add what the conſequences of ſuch management will be. The part of the ſeed, which has got an over-doſe, will be ſubjected to all the riſks he has mentioned, from the cauſtic quality of the urine and lime; and the remaining part, which has been either imperfectly moiſtened, or not moiſtened at all, will, by the vermin not being deſtroyed, produce blighted or ſmutted ears. When ſpeaking of the ſalt pickle, he has ſaid, that if powdered chalk or common whitening are uſed, it will deſtroy the inſects as effectually as lime, and that without the leaſt riſk to the grain, and has accordingly recommended it to be prepared in that way. The urine pickle he decidedly condemns, as it is in every point of view liable to inſuperable objections: for whether the urine is uſed ſingly, or in conjunction with lime, great miſchief may be done by it, if the wheat is either prevented by any accident from being ſown even for a ſingle night, or if it is ſown upon dry land, and the weather continues warm, and no rain falls for a conſiderable time afterwards; but if the urine pickle is ever had recourſe to, it will certainly be much milder, if chalk or whitening be employed as abſorbents in place of lime, than under other circumſtances.

But he is fully ſenſible that much oppoſition will be made to the doctrine here laid down concerning theſe pickles, eſpecially by thoſe who have been long accuſtomed to the uſe of them; and who, without knowing the riſk with which they are attended, have generally aſcribed the failure or deficiency of their wheat crop to other cauſes. But the ideas here held forth are by no means the offspring of conjecture, or a warm imagination. Careful trials have been made of each, under almoſt every variety of circumſtances that can occur, with this reſult;—that though, in a few fortunate caſes, both the ſalt and the urine pickles may be uſed without any ſeeming loſs or inconvenience, yet in a majority of all the inſtances in which they are employed, more or leſs of the ſeed periſhes from their effects. He has, for ſeveral years paſt, made trials of both pickles upon a given number of ſeeds, ſown at different periods of the ſeaſon, and under different circumſtances of heat and moiſture, and he has uniformly found that when wheat, pickled with ſalt and lime, was ſown either upon ground containing a moderate ſhare of moiſture, or had a ſlight ſhower ſoon after it was ſown, ſcarcely one grain in ten periſhed; whereas, when it was ſown upon warm dry land, and no rain fell for perhaps two or three weeks afterward, nearly a third of the ſeed never vegetated. And that when the urine pickle was uſed, even under the moſt fortunate circumſtances, two grains out of ten, or one-fifth part of the whole, was generally the leaſt failure that happened, even when it was ſown immediately after being pickled: but in caſes when it was kept a night or two in the pickle, nine-tenths of the ſeed have been known to periſh; and when ſown upon very dry land, and much dry warm weather followed, the loſs has alſo been very great. Theſe trials having been made with a given number of grains, the writer was enabled to aſcertain, with perfect accuracy, the proportion which periſhed in each experiment.

But with regard to the laſt ſort, or Italian pickle, it has not hitherto been ſufficiently in uſe fully to aſcertain in what reſpects it may be injurious, or beneficial, when made uſe of in preparing ſeed corn for being put into the ground. From the nature of the different ingredients, it would, however, ſeem to be a preparation of an active nature, and which ſhould be employed with caution, till more full experience has ſhewn its effects and advantages.

Pickle is alſo a term ſometimes applied to the grains of wheat, in diſcriminating its quality; thus we have a *lean* and a *hungry* pickle, &c.

PICKLED Fish. See Fish.

PICKLING *of Grain*, in *Agriculture*, the art of ſteeping it in pickles, in order to preſerve it, and prevent the crops from being diſeaſed.

It

It is sufficiently plain, from what has been observed in respect to pickles, that they are liquors of a very active nature, and which must be employed with considerable care, and nice attention to the circumstances of the weather and state of the land; as, without this, much injury and disadvantage, instead of benefit, may be the result. The length of time for effecting the purpose, in the safest manner, must also be had in the mind of the farmer; as the steeping of grain from twenty to twenty-four hours in solutions of wood-ashes and arsenic, as well as in lime-water, gave clean crops from extremely smutty seed; while the retaining it in these mixtures only a short time had but a comparatively trifling effect. In all cases, in using these pickles, great attention should likewise be paid to having the grain as equally as possible imbibed and impregnated with the liquors, as in this way the most beneficial effects must be produced.

But whatever danger there may be in pickling seed corn, for the purpose of preventing its being affected with the smut, it is a practice that is seldom or ever neglected in the northern parts of England, and in Scotland, without the farmers in these parts suffering from such omissions.

PICKOUAGAMIS, in *Geography*, a river of Canada, which runs from lake Shabamoushan to lake St. John.

PICLE, PICTELLUM, a small parcel of land inclosed with a hedge; a little close. This word seems to come from the Italian *picciola*, i. e. *parvus*; and in some parts of England is called *pightel*.

PICO, GIOVANNI, of Mirandola, in *Biography*, one of the most extraordinary persons of his time, surnamed the Phœnix, was the third son of Gianfranchesco Pico, prince of Mirandola, and Concordia. He was born in 1463, and almost from his childhood displayed an eager attachment to literature. At the age of 14 he was sent to Bologna to study canon law, but after spending two years there, he set out to visit the most celebrated schools in Italy and France. He went to Ferrara, where he was kindly received by his relation duke Hercules I., and studied under Batista Guarino. He had a great readiness in acquiring languages, and is said to have thoroughly understood twenty-two by the time he was eighteen years of age. This is probably an exaggeration. After he had employed seven years in his academical tour, he returned to Rome at the age of twenty-three. There he posted up 900 propositions appertaining to dialectics, morals, physics, mathematics, &c. offering to dispute with any antagonist whomsoever upon any one of them. This caused him to be looked upon with envy and jealousy, none daring to accept of his challenge. Thirteen of his propositions were however accused before the pope as contrary to sound doctrine. He published an elaborate defence of them addressed to Lorenzo de Medici, and after putting him to a considerable deal of trouble in justifying himself, he was acquitted of all blame. The effect of the anxiety produced by this business caused a total change in his course of life, and though young, rich, elegant in person and manners, and in some degree habituated to pleasure, he gave himself up to devotion, and confined his future studies to theological subjects. He fixed his abode in Florence, where he enjoyed the intimacy of several illustrious characters, among whom was Lorenzo de Medici, who testified his affection for him by calling him to a parting embrace on his death-bed. His high reputation caused him to be thought of for the cardinalate, but it does not appear that any steps were taken to advance him to that dignity. At this period he had a most enthusiastic desire to be useful, and he resolved to distribute all his property among the poor, and travel bare-footed through the world to preach the gospel. An early death, at the age of 32, put an end to his projects. The writings of Pico display an acute genius, and a vast extent of learning, but they added very little to true science. His principal works are "Hexaplus, or an Explanation of the Six Days of Creation;" "Adversus Astrologiam Divinatricem;" Epistolarum, lib. viii.

PICO, GIANFRANCESCO, prince of Mirandola, nephew of the preceding, being son of his brother Galeotto, was born in 1470. He studied at Ferrara, and manifested, like his uncle, an early attachment to literature. After the death of his father, he succeeded to the sovereignty of Mirandola, an elevation which proved the source of many troubles. His brother Lodovico, who had married a daughter of general Trivulzi, was his competitor, and by the assistance of a third brother, he expelled Gianfrancesco in 1502. He was restored by the arms of pope Julius II. in 1511, but was again dethroned, and on the 15th of October, 1533, Galeotto, nephew of Lodovico, with a band of armed men surprised Mirandola, and entering the chamber of Gianfrancesco, put him and one of his sons to death, and then imprisoned his wife and younger son. He was probably much better fitted for a private than a public station. In the midst of all the changes of fortune, religion and letters were his chief solace. He was in habits of correspondence with all the eminent literary characters of his time, many of whom held him in the highest estimation. He was author of many works, but that by which he is best known is a life of his uncle, containing much curious information respecting that extraordinary man. He also composed a life and apology of the famous Savonarola.

PICO, or the PEAK, in *Geography*, one of the Azores, which derives its name from a high mountain, terminating in a peak. This volcanic mountain is by some reported to be equal to the peak of Teneriffe in height. Mr. Adanson, who visited these islands in his return from Senegal in 1753, says that the peak is about half a league in perpendicular altitude, which, allowing the French league to be 2450 toises, would give a moderate height, not exceeding 7350 feet. The peak would form a very convenient first meridian, from which to reckon the longitude. The dimensions of the island are about 30 British miles in length, and 10 in breadth. The chief places are Pico, Lagoas, Santa Cruz, San Sebastian, Pasquin, San Rocko, Playa, and Magdalena. The island is productive; its cattle are numerous, of various kinds, and excellent; its wine is highly commended; and it furnishes a considerable quantity and variety of wood, particularly the cedar and teixo, which is solid and hard as iron, and veined when finely polished. The inhabitants live wholly on the produce of their own island in plenty and comfort. Pico carries on a considerable trade in wine, which seems to be sold as Canary. N. lat. 38° 30′. W. long. 28° 16′.

PICO, a mountain of Spain, on the confines of New and Old Castile, and Estremadura.

PICO, or *Puerto de Pico*, a town of Spain, in Old Castile, on a mountain, near the source of the Tormes.

PICO *Sacro*, a mountain of Spain, in Galicia; nine miles S. of Santiago.

PICO *Teneriffe*, a mountain of Barbadoes; one mile S. of Cuckold's point.

PICO *el Teja*, a town of Spain, in Old Castile; 20 miles W.S.W. of Segorbe.

PICO *d'Urbino*, a mountain of Spain, in Old Castile; 12 miles S. of Calzada.

PICOLATA, a fortress of East Florida, on the river St. John; 27 miles from St. Augustine.

PICOLET POINT, a point on the N. side of the island of St. Domingo, that forms the W. boundary of the bay which

which ſets up to cape Francois. Under its cannon ſhips have been ſecured in time of war.

PICOLO, a town of Italy, in Friuli; ſix miles S. of Udina.

PICOLOS, the name of an ancient Pruſſian idol, to which human ſacrifice was offered. See POTRIMPOS.

PICOSA, or PISANA, in *Geography*, mountains of the coaſt of Peru, extending about ſeven leagues between Colamahe river and Salango iſland, S. of the equator, and ſerving for the direction of mariners.

PICOTA, a name given by ſome authors to a diſtemper which they deſcribe as conſiſting wholly in an eruption of a number of very minute pimples upon the ſkin, all over the body; it is attended with no danger, unleſs they are ſtruck in.

PICOY, in *Geography*, a town of Peru, in the dioceſe of Guamanga, on a river of the ſame name, which runs into the Xauxa, 20 miles N. of Guanca Velica.

PICQUEERING, PICKEERING, or *Pickerooning*, a little flying war or ſkirmiſh, which the ſoldiers make when detached from their bodies to pillage, or before a main battle begins.

PICQUET, or PICKET, a celebrated game at cards, much in uſe throughout the polite world.

It is played between two perſons, with only thirty-two cards; all the duces, threes, fours, fives, and ſixes, being ſet aſide.

In reckoning, at this game, every card goes for the number it bears, as a ten for ten; only all court-cards go for ten, and the ace for eleven: and the uſual game is one hundred up. In playing, the ace wins the king, the king the queen, and ſo down. Twelve cards are dealt around, uſually by two and two; which done, thoſe that remain are laid in the middle. If one of the gameſters finds he has not a court card in his hand, he is to declare he has *carte blanche*, and tell how many cards he will lay out, and deſire the other to diſcard, that he may ſhew his game, and ſatisfy his antagoniſt, that the *carte blanche* is real; for which he reckons ten.

Each perſon *diſcards*, *i. e.* lays aſide a certain number of his cards, and takes in a like number from the ſtock. The firſt, of the eight cards, may take three, four, or five; the dealer all the remainder, if he pleaſes.

After diſcarding, the eldeſt hand examines what ſuit he has moſt cards of; and, reckoning how many points he has in that ſuit, if the other have not ſo many in that, or any other ſuit, he tells one for every ten of that ſuit. He who thus reckons moſt is ſaid to win the *point*.

The point being over, each examines what *ſequences* he has of the ſame ſuit; *viz.* how many tierces, or ſequences of three; quarts, or fours; quintes, or fives; ſixiemes, or ſixes, &c. For a tierce they reckon three points, for a quarte four, for a quinte fifteen, and for a ſixieme ſixteen, &c. And the ſeveral ſequences are diſtinguiſhed in dignity by the cards they begin from: thus, ace, king, and queen, are called *tierce major;* king, queen, and knave, *tierce to a king;* knave, ten, and nine, *tierce to a knave*, &c. and the beſt tierce, quarte, or quinte, *i. e.* that which takes its deſcent from the beſt card, prevails; ſo as to make all the others in that hand good, and deſtroy all thoſe in the other hand. In like manner, a quarte in one hand ſets aſide a tierce in the other.

The ſequences over, they proceed to examine how many aces, kings, queens, knaves, and tens, each holds; reckoning for every three, of any ſort, three; but here too, as in ſequences, he that with the ſame number of threes has one that is higher than any the other has, *e. gr.* three aces, has all his other made good hereby, and his adverſary's are all ſet aſide. But four of any ſort, which is called a *quatorze*, always ſet aſide three.

All the game in hand being thus reckoned, the eldeſt proceeds to play, reckoning one for every card he plays above a nine, and the other follows him in the ſuit: and the higheſt card of the ſuit wins the trick. Note, unleſs a trick be won with a card above a nine (except the laſt trick), nothing is reckoned for it: though the trick ſerves afterwards toward winning the cards; and that he who plays laſt does not reckon for his cards, unleſs he win the trick.

The cards being played out, he that has moſt tricks reckons ten for *winning the cards*. If they have tricks alike, neither reckons any thing. The deal being finiſhed, and each having marked up his game, they proceed to deal again as before; cutting afreſh each time for the deal.

If both parties be within a few points of being up, the carte blanche is the firſt thing that reckons; then the point, then the ſequences, then the quatorzes or threes, then the tenth cards.

He that can reckon thirty in hand by carte blanche, points, quintes, &c. without playing, before the other has reckoned any thing, reckons ninety for them; and this is called a *re-pique*. If he reckons above thirty, he reckons ſo many above ninety. If he can make up thirty, part in hand, and part in play, before the other has told any thing, he reckons for them ſixty. And this is called a *pique*. Whence the name of the game.

He that wins all the tricks inſtead of ten, which is his right, for winning the cards, reckons forty; and this is called a *capot*.

This game has, in ſome caſes, been the object of mathematical computation.

Thus M. de Moivre has propoſed and ſolved the following problems:

1. To find at picquet the probability which the dealer has for taking one ace or more in three cards, he having none in his hand. He concludes from his computation, that it is 29 to 28 that the dealer takes one ace or more.

2. To find at picquet the probability which the eldeſt has of taking an ace or more in five cards, he having no ace in his hand. Anſwer; 232 to 91, or 5 to 2, nearly.

3. To find at picquet the probability which the eldeſt hand has of taking an ace and a king in five cards, he having none in his hand. Anſwer; the odds againſt the eldeſt hand taking an ace and a king are 331 to 315, or 21 to 20 nearly.

4. To find at picquet the probability of having twelve cards dealt to, without king, queen, or knave; which caſe is commonly called *cartes blanches*. Anſwer; the odds againſt *cartes blanches* are 1791 to 1 nearly.

5. To find how many different ſets, eſſentially different from one another, one may have at picquet before taking in. Anſwer; 28,967,278. This number falls ſhort of the ſum of all the diſtinct combinations, whereby twelve cards may be taken out of 32, this number being 225,792,840; but it ought to be conſidered, that in that number ſeveral ſets of the ſame import, but differing in ſuit, might be taken, which would not introduce an eſſential difference among the ſets.

M. De Moivre alſo gives ſome obſervations on this game which he had from an experienced player. See Doctrine of Chances, p. 179, &c.

M. de Monmort has alſo treated of picquet in his Analyſe des jeux de Hazard, p. 162.

Picquet *Guard.* See Guard.

Picquet-*Berg*, in *Geography*, a diviſion of the diſtrict of Stellenboſch and Drakenſtein in ſouthern Africa, near the Cape of Good Hope. It terminates the plain of the Four-and-twenty rivers to the northward. Here, beſides corn and fruit, the inhabitants rear horſes, horned cattle, and ſheep. And from hence alſo is ſent to the Cape market a conſiderable quantity of tobacco, which has the reputation of being of the beſt quality that ſouthern Africa produces.

PICQUIGNY, a town of France, in the department of the Somme, and chief place of a canton, in the diſtrict of Amiens. The place contains 1253, and the canton 14,125 inhabitants, on a territory of 202½ kiliometres, in 22 communes.

PICRA, Hiera. See Hiera.

PICRAMNIA, in *Botany*, ſo named by Swartz from πικρος, *bitter*, and θαμνος, *a ſhrub*, on account of the great bitterneſs of every part of the plant. Swartz. Prodr. 27. Fl. Ind. Occ. 217. Schreb. 687. Willd. Sp. Pl. v. 4. 761. Ait. Hort. Kew. v. 5. 384.—Claſs and order, *Dioecia Pentandria.* Nat. Ord. uncertain; perhaps akin to *Rhus.*

Gen. Ch. Male, *Cal.* Perianth of one leaf, in three or five deep, lanceolate, erect ſegments. *Cor.* Petals three or five, lanceolate, ſomewhat ſpreading, longer than the calyx. *Stam.* Filaments three or five, awl-ſhaped, approximated at the baſe, erect, longer than the corolla; anthers ovate, two-lobed.

Female, on a different plant, *Cal.* as in the male, permanent. *Cor.* as in the male. *Piſt.* Germen (ſuperior?) oblong, rather compreſſed; ſtyles two, ſhort, recurved, permanent; ſtigmas ſimple, acute. *Peric.* Berry roundiſh-ovate, of two cells. *Seeds* two in each cell, ovate-oblong.

Eſſ. Ch. Male, Calyx in three or five deep ſegments. Petals three or five. Stamens three or five.

Female, Calyx and Corolla like the male. Styles two. Berry of two cells. Seeds two in each cell..

Obſ. The berry is ſaid to have ſometimes, though very rarely, three cells, and ſolitary ſeeds.

1. P. *Antideſma.* Aſh-leaved Picramnia. (Berberis fruticoſa racemoſa, fraxini folio alato, fructu nigro dipyreno; Sloane Jam. v. 2. 101. t. 208. f. 2. Antideſma; Browne Jam. 123.)—Cluſters ſlender, pendulous. Stamens three. Styles recurved.—Native of Jamaica and Hiſpaniola; brought to Kew by admiral Bligh's ſhip in 1793, but it has not yet bloſſomed. The *ſtem* is nine or ten feet high, according to Sloane, as thick as a man's arm, ſmoothiſh. *Leaves* ſcattered, pinnate, of about ſeven ſmooth, elliptical, nearly entire, leaflets. *Cluſters* long, looſe, of numerous little yellowiſh-white *flowers*. *Berries* the ſize of gooſeberries, at firſt red, then black, ripe in November. The negroes eſteem this ſhrub antiſyphilitic, and uſe its infuſion as a remedy for the colic.

We quote Willdenow after the Hort. Kew. without having that part of his work at hand, ſo that we know not whether he deſcribes, as the ſpecific character ſeems to imply, more than one ſpecies.

PICRIA, ſo called by Loureiro, from πικρια, *bitterneſs*, on account of the flavour of every part of the plant. Lour. Cochinch. 392.—Claſs and order, *Didynamia Angioſpermia*, or rather perhaps *Diandria Monogynia.* Nat. Ord. *Perſonatæ*, Linn. *Scrophulariæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, four-leaved, deciduous; two of the leaves ovate, flat, longer than the corolla; two others alternate, linear, ſhorter. *Cor.* tubular, ringent; tube contracted in the middle; upper lip ſpatulate, emarginate; lower broadeſt, in three rounded equal ſegments. *Stam.* Filaments four; the two longeſt erect, ſeparately ſheathed with papillary tubes; their anthers of one cell, curved, diſtant; two ſhorter inflexed; their anthers connected together, each of two cells. *Piſt.* Germen ovate; ſtyle the length of the corolla; ſtigmas two, lanceolate, erect. *Peric.* Berry ovate, inferior, of two cells. *Seeds* very numerous, roundiſh.

Eſſ. Ch. Calyx of four leaves. Corolla ringent. Berry inferior, of two cells.

1. P. *Fel-terræ.* Cultivated in the gardens of China and Cochinchina. The leaves are eſteemed for their aperient, ſudorific, diuretic, and emmenagogue properties; and uſed in incipient dropſy, intermittent fevers, colics, and various ſuppreſſions. The *ſtems* are numerous, herbaceous, perennial, eighteen inches high, erect, ſquare, branched. *Leaves* oppoſite, ovate, ſerrated, rough, but not hairy. *Flowers* pale red, crowded, ſtalked, axillary, and terminal.—Such is Loureiro's deſcription. We find no notice of this genus in other writers; yet it muſt be preſumed that a plant ſo generally cultivated, and of ſo good report as to its medical uſes, can hardly have eſcaped the notice of botanical travellers. Many points indicate an affinity to *Gratiola*, but the fruit being a berry, and inferior, is foreign to that genus, nor can we, by any probable conjecture, reduce Loureiro's plant to any other with which we are acquainted.

PICRIDIUM, ſo called from its bitterneſs, a genus eſtabliſhed by Desfontaines in his *Flora Atlantica*, the only two ſpecies of which, mentioned by that able writer, are *P. tingitanum* and *P. vulgare.* The firſt is *Scorzonera tingitana*, the other *Scorzonera picroides*, of Linnæus. Both are removed by Willdenow to *Sonchus*, a meaſure adopted in the Prodr. Fl. Græc. v. 2. 126; nor can we trace any thing like an eſſential difference, in the character given by Desfontaines, to ſeparate them from that genus, with which moreover they well accord in habit.

PICRIS, from πικρος, *bitter*, a name for the wild ſuccory, or ſome bitter herb of that family. It is well choſen for the preſent genus, inferior to few of its natural order in this reſpect. Linn. Gen. 399. Schreb. 526. Willd. Sp. Pl. v. 3. 1556. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 814. Prodr. Fl. Græc. Sibth. 131. Ait. Hort. Kew. v. 4. 447. Juſſ. 170. Lamarck Illuſtr. t. 648. Gærtn. t. 159. (Helmintia; Juſſ. 170. Willd. Sp. Pl. v. 3. 1607. Ait. Hort. Kew. v. 4. 461. Lamarck Illuſtr. t. 648. Gærtn. t. 159.)—Claſs and order, *Syngeneſia Polygamia-æqualis.* Nat. Ord. *Compoſitæ ſemifloſculoſæ*, Linn. *Cichoraceæ*, Juſſ.

Gen. Ch. *Common calyx* double; the outer of ſeveral flat, lax, converging ſcales; inner ovate, of many equal parallel ſcales. *Cor.* compound, imbricated, uniform, of numerous monopetalous, ligulate, linear, abrupt, five-toothed, perfect florets. *Stam.* Filaments five, capillary, very ſhort; anthers united into a cylindrical tube. *Piſt.* Germen to each floret nearly ovate; ſtyle the length of the ſtamens; ſtigmas two, reflexed. *Peric.* none, except the permanent calyx, finally reflexed. *Seeds* ſolitary, ſwelling, obtuſe, tranſverſely furrowed; down feathery, ſeſſile or ſtalked. *Recept.* naked.

Eſſ. Ch. Receptacle naked. Calyx double; the inner equal; the outer lax. Down feathery. Seeds tranſverſely furrowed.

Obſ. The inner calyx is by no means imbricated. Its ſcales, or leaves, are parallel, cloſe, all of equal length. The Helmintia of authors, ſee that article, conſiſts of the firſt of our ſpecies only; its outer calyx has but five leaves, the inner about eight; and the ſeed-down is ſtalked. The habit alfo is rather peculiar; but we are always on our guard againft the unneceffary multiplication of genera, that fnare to the moft accurate obfervers.

1. P. *echioides.* Briftly Ox-tongue. Linn. Sp. Pl. 1114. Curt. Lond. fafc. 3. t. 51. Engl. Bot. t. 972. (Helmintia echioides; Willd. Sp. Pl. v. 3. 1607. Buglossum luteum; Ger. Em. 798.)—Outer calyx of five broad prickly leaves. Down ftalked. Leaves wavy.—Native of banks and the borders of fields, efpecially on a clay foil, in England, France and Italy, flowering in June and July. The *root* is annual. *Herb* two or three feet high, branched, bright green, copioufly befet with rigid pungent prickles, of which thofe on the difk of the *leaves* proceed each from a hard tubercle. Lower *leaves* lanceolate; upper heart-fhaped and clafping the ftem. *Flowers* rather large, of a bright golden yellow. The plant abounds with a bitter milky juice; yet Dr. Sibthorp found the leaves in ufe among the modern Athenians, either raw, as an ingredient of their fallads, or boiled as a pot-herb.

2. P. *hieracioides.* Hawkweed Ox-tongue. Linn. Sp. Pl. 1114. Willd. n. 1. Ait. n. 1. Engl. Bot. t. 196. (Hieracium afperum; Ger. Em. 298.)—Stem rough. Outer calyx many-leaved, fhort, lax. Leaves lanceolate, wavy; the radical ones toothed. Down feffile.—Found about dry gravelly banks, and the borders of fields, in the north of Europe; not rare in the chalk or gravel counties of England; flowering in July and Auguft. *Root* biennial. *Herb* corymbofe and widely fpreading, dark green, rough. *Flowers* yellow, with a broader corolla, but fmaller calyx, than the former.

3. P. *japonica.* Japanefe Ox-tongue. Thunb. Jap. 299. Willd. n. 2.—Stem hifpid. Leaves feffile, lanceolate, hairy, toothed. Flowers panicled. Calyx hifpid; the outer one erect.—Native of hills in Japan, flowering in April or May. *Stem* two feet high, hifpid. Lower *leaves* a finger's length, fomewhat ftalked; upper fhorter and feffile, alternate. *Flowers* yellow, panicled, on long, naked, hifpid, compound ftalks.

4. P. *aculeata.* Prickly Ox-tongue. Vahl Symb. v. 2. 89. Willd. n. 3.—Stem very prickly. Leaves elliptic-lanceolate, toothed. Flowers corymbofe. Calyx hifpid; the outermoft lax.—Native of uncultivated hills in Barbary. Perennial. A foot high, rough all over with copious fmall rigid prickles. Vahl defcribes it as differing from *P. echioides* in the want of a five-leaved outer *calyx;* yet he fays there is an outer *calyx*, only all the calyx-fcales are linear-lanceolate. Such is the cafe with every fpecies except *echioides.*

5. P. *pauciflora.* Few-flowered Ox-tongue. Willd. n. 4. Prodr. Fl. Græc. n. 1912.—Stem hairy. Leaves lanceolate, feffile, toothed. Flower-ftalks elongated, fwelling. Calyx hairy; the outermoft lax.—Native of the fouth of France and of Greece. It was raifed in Chelfea garden in 1788, as well as in that of the late Dr. Gwyn at Ipfwich, from feeds given to the writer of this by M. Gerard. The *root* appears to be annual. *Stem* from eight to twenty-four inches high, more or lefs branched, fpreading, rough with fhort briftly cloven-pointed hairs, as is all the herbage. *Flowers* yellow, of an ordinary hawkweed afpect, open in the morning only. Villars's figure of his *Hieracium pappoleucum*, Dauph. t. 31, is a very tolerable reprefentation of this plant, as Willdenow has likewife noted; but fpecimens from the author himfelf prove very different from our *Picris.*

6. P. *afplenioides.* Spleenwort-leaved Ox-tongue. Linn. Sp. Pl. 1115. Willd. n. 5. Vahl. Symb. v. 2. 90. Prodr. Fl. Græc. n. 1913. Ait. n. 2. (Leontodon muricatum; L'Herit. Stirp. 173. t. 82. Virea fcabra; Scop. Del. Infub. v. 2. 25. t. 13.)—Stem rough. Leaves oblong-lanceolate, obtufe, finuated. Flower-ftalks elongated, fwelling. Calyx rough; the outermoft reflexed.—Native of the fandy fea-coaft of Barbary. Perennial. Much larger than the laft, with blunt, ftrongly finuated, or pinnatifid, *leaves;* and fome of the *feed-down* is ftalked, which greatly invalidates the fuppofed character of *Helmintia*, as a diftinct genus.

7. P. *ruderalis.* Rock Ox-tongue. Willd. n. 6.—Stem hifpid. Leaves lanceolate, with fringe-like teeth. Flower-ftalks and calyx hifpid; the outermoft fpreading. Found on rocks near Prague in Bohemia. *Schmidt.* *Root* perennial, abrupt. *Stems* feveral, fix inches high, erect, befet from top to bottom with axillary, diftant, very hifpid *flower-ftalks.* The *flowers* are fmall, like *Crepis tectorum.* Willd.

8. P. *hifpida.* Hifpid Ox-tongue. Ait. n. 3.—Leaves oblong-lanceolate, nearly entire, feffile, hifpid, as well as the calyx, with hairs barbed at the point.—Native of the Levant. A fpecimen in the Bankfian herbarium, it is faid, fhews this plant to have been cultivated before 1789, in the gardens of England. It is marked as a hardy perennial, flowering in July and Auguft. We have had no opportunity of examining this fpecies, but we greatly fufpect it to be no other than our *pauciflora*, whofe pubefcence anfwers to the defcription, and which we believe was communicated to fir J. Banks, as well as to Kew garden, in 1788 or 1789.

PICRIUM, from πικρος, *bitter*, an appellation for which Schreber has exchanged the barbarous *Coutoubea* of Aublet. Schreb. Gen. 791. Mart. Mill. Dict. v. 3. See Exacum.

PICROTOXINE, in *Natural Hiftory*, a name given by M. Boulley to a peculiar fubftance, which he extracted from the "Cocculus indicus," and to which that fubftance owes its deleterious qualities. It may be obtained by the following procefs. Boil the feeds deprived of their pericarp in a fufficient quantity of water; filter the decoction, and precipitate it by acetate of lead; then filter again, and evaporate flowly to the confiftence of an extract; diffolve this extract in alcohol, and evaporate the folution to drynefs. Repeat thefe folutions in alcohol and evaporation, till the refidue is wholly foluble in alcohol and water. It then confifts of picrotoxine mixed with a little colouring matter; agitate it with a very fmall quantity of water, the colouring matter is diffolved, and the picrotoxine feparates in fmall cryftals. Its properties are as follow: its colour is white, and it cryftallizes in four-fided prifms; its tafte is difguftingly bitter; 100 parts of boiling water diffolve four parts of picrotoxine, one-half of which feparates as the folution cools; the folution does not alter the colour of vegetable blues; alcohol, of the fpecific gravity 0.810, diffolves the third of its weight of this fubftance; a little water throws down the picrotoxine, and the addition of a greater quantity rediffolves the precipitate; fulphuric ether, of the fpecific gravity 0.700, diffolves only 0.4 of picrotoxine; it is infoluble in oil, both fixed and volatile; diluted fulphuric acid does not act upon it; concentrated acid diffolves it, affuming a yellow colour; when heat is applied, the picrotoxine is changed and deftroyed; nitric acid diffolves it without the difengagement of nitrous gas; the folution is yellowifh-green; when heat is applied, the picrotoxine is converted into oxalic acid; but about eighteen parts of nitric acid are requifite to produce this effect:—muriatic, oxymuriatic, and fulphureous acids, do not act upon it:—acetic acid readily diffolves it:—carbonate of potafh precipitates it from this folution unaltered:—potafh, foda, and ammonia, diluted with ten times their weight of water, readily diffolve picrotoxine:—when triturated with potafh, it affumes a yellow colour, but does not emit the odour of ammonia:—

 when

when heated, it burns without melting, or flame, exhaling a white smoke, which has a resinous odour:—when distilled, it yields very little water, and gaseous products, but much yellow-coloured empyreumatic oil, and a brilliant bulky charcoal remains behind. Annal. de Chim. vol. 80.

PICTA Toga. See Toga.

PICTAVIENSIS, or Pictonum *Colica*, the *colic of Poictou*, called also the *painter's colic*, *Devonshire colic*, and, in the West Indies, the *dry belly-ache*, is now known to be occasioned solely by the poison of lead, and is more properly called the *saturnine colic*. See Colica.

PICTOU, in *Geography*, a growing settlement of Nova Scotia, in the county of Halifax, built on the bay of Pictou, on the N.E. coast of the province, nearly opposite to the S.E. end of the island of St. John's, and about 100 miles distant from Halifax, with which it has a free and speedy communication. It contains 40 houses, and 500 inhabitants, mostly Scots. Formerly it was inconsiderable, but now is the most flourishing place in the province. Its trade consists chiefly in the exportation of timber, annually shipped to Great Britain and Ireland, in return for which are imported dry goods.

PICTS, in *History*, a denomination given to the inhabitants of the eastern parts of Scotland, concerning whose origin, the etymology of their name, and various particulars relating to them, antiquarians, after all their researches, have been divided almost to the present day; though we have reason to believe, that the principal questions in dispute with regard to these people are now nearly settled. The first mention of them under this denomination occurs in a panegyric of Eumenius, the orator, during the year 297, and again in 308; who, referring to Constance's arrival in Britain in 306, for the purpose of repelling the Caledonians and "other Picts" (*Caledones aliique Picti*), expressly and significantly represents them as the same people. The Caledonians had been often mentioned before by classic authors, under other names; but on this occasion they were called Picts, on account of their peculiar seclusion from the Roman provincials on the south; and they were often mentioned, during the decline of the Roman empire, by orators, historians, and poets, under that significant appellation. As the learned professor of Autun knew the meaning of his own language, says Mr. Chalmers, we are bound to regard the Caledonians and Picts as the same people, at the end of the third century. Towards the conclusion of the fourth century, Ammianus Marcellinus (l. xxvii. c. 7.) spoke of these people in the same manner. The poets also, referring to the custom of painting themselves, that prevailed among the Caledonians, and perhaps erroneously imagining that they were on this account called *Picti*, confirm the same opinion. Thus Claudian, about the year 400, "De Bello Getico," alludes to them in the following lines:

> " ——— ferroque notatos
> Perlegit exanimos Picto moriente figuras."

And in his panegyric on Theodosius's victories, he again thus speaks of the Picts:

> " Ille leves Mauros, nec falso nomine Pictos
> Edomuit."

It appears, therefore, from the mention of classic authors, during three centuries, that the Picts were Caledonians. That the Caledonians were the North Britons, who fought Agricola, at the foot of the Grampian, we know from the nature of the events, and the attestation of Tacitus; and that the Northern Britons of the first century were the descendants of the Celtic aborigenes, who were the same people as the Southern Britons, during the earliest times, has been satisfactorily proved, says Chalmers, as a moral certainty.

At the period of the Roman abdication, A.D. 446, when the Pictish period commenced, the sixteen tribes of Picts, under this appropriate denomination, ranged unsubdued beyond the wall of Antonine, and acquired from their independence higher importance, when they were no longer overawed by the Roman power. By degrees they became the ruling nation, and retained their dominion throughout four centuries of the North British annals, *viz.* until A.D. 843, when the Pictish period terminated. It has been a subject of dispute, as we have already intimated, whether the Picts were of a Celtic, or of a Gothic origin; but it has been shewn, on the most satisfactory evidence, that their genealogy may be clearly traced through three successive changes; from the Gauls to the Britons; from the Britons to the Caledonians; and from the Caledonians to the Picts; thus changing their names, but not their nature. The venerable Bede, who was contemporary with the Pictish government, speaks doubtfully of the Picts, as the second people, who came into this island from Scythia; first to Ireland and thence to North Britain, and many later writers have been misled by his authority; but it has been since concluded, from more accurate examination, that the Picts were undoubtedly Caledonians, that the Caledonians were Britons, and that the Britons were Gauls, or Celts. Towards the conclusion of the third century, the Caledonians acquired the comprehensive appellation of Picts; and this appellation, before the end of the fourth century, superseded every other name. Some writers, indeed, maintained, with Buchanan, that a great part of North Britain was, even before the invasion of Britain by the Romans, inhabited by a people called Picts, Piks, or Pechts, who are thought by some to have migrated from Scandinavia, and to have driven out the ancient inhabitants; nevertheless it is said, that they were a Celtic colony, and spoke at least a dialect of the language of the original inhabitants. But for these assumptions there seems to those who have been industrious in their researches no sufficient authority. Camden, whose testimony commands deference and respect, is the first person of eminence who avowed it as his opinion, that the Picts were the genuine descendants of the ancient Britons; and Selden, having duly considered the subject of the origin of the Picts, advises the reader, rather to adhere to the learned Camden, who makes the Picts very genuine Britons, distinguished only by an accidental name. Different etymologies have been given of the name *Picti*. The most probable opinion is, that these distinguished descendants of the Caledonians acquired this name, during the Roman period, from their relative situation, and local qualities, as compared with the romanized Britons, who lived in the province of Valentia, within the Roman wall; whereas the Picts dwelt without the province, and roamed free from the Roman authority, and separated from the romanized tribes within, who often felt their rigorous incursions, and frequently required the protection of the Roman government. In the British speech, the Picts were from these distinctive qualities called "Peithi," which was naturally latinized by Roman writers into "Picti," when, during the third century, they came to be the objects of Roman observation, by assimilating the British term to their own familiar word "Picti," which was descriptive of the custom of painting the body, seen by the Romans among the Northern Britons. "Peithi" in the British language signifies "those that are out or exposed," "the people of the open country," or of the waste and desart; and also those "who scout, or lay waste." Accordingly the "Peithi" and "Peith-wyr" are the terms commonly

commonly ufed by the Welfh poets for the Pictifh people; and on the confines of Wales, thofe Britons who threw off their allegiance to their native princes, and fet up a *regulus* of their own, or adhered to the Saxons, were called "Peithi" or "Picti." Moreover, the Welfh, in order to diftinguifh the northern from the fouthern Picts, called the Caledonian Picts by the appellation of "Gwyddyl Pichli," or "Fichli;" the *p* of the Britifh being often changed into *f*. We may here add, that the Welfh, as Owen obferves, in his Dictionary, apply the term "Brython," and Brythonig, to the Picts, and hence it has been inferred, that the Welfh confidered them as Britons.

Innes, in his "Critical Effay," has given from an ancient chronicle a feries of the Pictifh kings, comprehending forty, who fucceeded one another from Druft, the fon of Erp, A.D. 451, to Bred, the laft, A.D. 843. Thefe Pictifh kings fucceffively governed uncivilized clans, during the rudeft ages. In the third century, they were in a high degree barbarous; but in procefs of time they gained fome improvement from their intercourfe, either civil or hoftile, with the romanized Britons, or Roman armies, and ftill more from the introduction of Chriftianity among them.

The appropriate country of the Picts acquired different names, in fucceffive periods. The mountainous part of it was denominated by the firft colonifts in their native fpeech "Alban," *i.e.* the fuperior height. This appellation, originally applied to the hilly region that forms the weft of Perth, and the north-weft of Argyle, was in fubfequent times extended to the whole country. In the firft century, the Britifh term "Celyddon," literally fignifying the "Coverts," was applied by the Roman authors to the whole country on the N. of the Friths, though the fame name was reftricted by the Roman geographers to the interior highlands, lying northward of Alban: and both thefe appellations were afterwards applied more largely to North Britain. The Pictifh chronicle, from the Pictifh people, called their country "Pictavia." The annals of Ulfter generally mention this country under the name of "Fortruin," derived, with a flight variation, from "Fother," the name of the Pictifh capital. Saxo, the Danifh hiftorian, plainly refers to "Petia," as the name of Pictland; and this "Petia" of Saxo approaches the neareft to the Britifh term "Peith," or "Peithw," which the Britifh people applied to the open country, lying along the eaft coaft, on the northward of the Forth. In the fequel of this article, we fhall merely mention fome incidental circumftances that occur in the hiftory of the Picts. The reign of Bridei was rendered illuftrious by his converfion to Chriftianity, under the inftruction of Columba, in 565. From this epoch, the Picts may be confidered as Chriftians, though this change in the profeffion feems not to have produced any confiderable alteration in their principles, or their cuftoms. About the year 724, a civil war commenced among the Picts, and they were at the fame time expofed to the deftructive incurfions of their enterprifing neighbours, on the north-eaft. The anarchical governments of Norway, Sweden, and Denmark, during the middle ages, produced the pirate kings of the northern feas, and thefe were for a long time the fcourges of the navigators, who failed from every nation, on the European feas. In 839 the Vikingr, as they were called, landed among the Picts, and a bloody conflict enfued, which proved fatal to many of the Pictifh chiefs. Weakened by domeftic ftrife, and by a formidable invafion, the Picts were unable to refift the arms, or to defeat the policy of Kenneth, the fon of Alpin, when he acquired their diftracted government, A.D. 843.

With regard to the *language* of the Picts, it has been obferved, that as they were merely the Cambro-Britons, who appeared at various periods under a new and lafting name, the fpeech of the Britons and of the Picts muft have been the fame. Accordingly Aber-nethy, the metropolis of the Pictifh kingdom, derived from the Britifh language its appropriate appellation, which it retained till the lateft period of the Pictifh government; and upon inveftigation, which we have not room to purfue, it has been found that the moft ancient repertory of Pictifh language is the topography of North Britain. The Pictifh language may alfo be traced in the vernacular language of North Britain even at this day: and the municipal law of that country has even borrowed feveral of its fignificant terms from the Pictifh fpeech. This language of the Britons and Picts has been confidered, by judicious writers, as mafculine, copious, and poetical. Although from not feeing it, in its primitive orthography, it feems to be harfh, in its founds, to the ears of ftrangers, yet, when it is put into verfe, and is read with its genuine pronunciation, it is, like the Greek and the Hebrew, melodious and ftrong. As the Celts were the original fettlers of Weftern Europe, they tranfmitted to their pofterity an energetic paffion, for impofing their own fignificant names on all the prominent objects of nature. In exercifing this peculiar prerogative of firft difcoverers, they difplayed thofe appropriate qualities of their language, which have been remarked; its ftrength and difcrimination, its copioufnefs of epithet, and its frequency of metaphor. In the fubfequent progrefs of the Gothic tribes over Europe, they adopted the names of mountains, rivers, &c. which had been impofed upon them by the Celts who had previoufly occupied the countries of which they took poffeffion; and the Saxons, who fettled in Britain, were prompted, by their poverty of fpeech, to follow the example of their Gothic fathers. The Anglo-Saxons, who, in more recent times, acquired fettlements in North Britain, borrowed many words from the Celts and Britons, and Scoto-Irifh, which have maintained their place, and which give ftrength, copioufnefs, and ornament to the Scoto-Saxon of the prefent times.

The *religion*, as well as the *language*, of the Picts, derived its origin from thofe of the Gauls; and hence we may conclude that the Picts and the Britons were the fame people, as well as from the identity of their fpeech, topography, and monuments. The tenets and the forms of the Pictifh religion were Druid in the fixth century; as we know from a thoufand relics of ftone that ftill engage attention within the diftrict of the Pictifh country. The modes of fepulture were the fame among the Picts as thofe of the Caledonians, and the fepulchral rites of the latter were the fame as thofe of the Britons. Their hill forts, their weapons of war, their ornaments, and their modes of life, were the fame as thofe of the Caledonian Britons, of whom the Picts were the immediate defcendants. That the Caledonians and Picts were the fame people is now univerfally allowed. Buchanan, Camden, Lloyd, Jones, the M'Pherfons, O'Connor, d'Anville, and Stillingfleet, however they may differ in other points, are here all agreed. But fome have afferted, without proof, and againft probability, that the Caledonians were a Gothic colony, who conquered North Britain in fome unknown age. With regard to any Gothic expedition for this purpofe, hiftory is filent. Few queftions have engaged more general attention among learned antiquaries than that of the origin of the Picts. Mr. Chalmers has given a minute detail of the different opinions that have been maintained with regard to this queftion; and he concludes with adducing the teftimony of the learned antiquary, Mr. Edward King, the author of the "Munimenta Antiqua;"

tiqua;" who maintains, that the Picts were descended from the aboriginal Britons. With him concurs the late Dr. Henry, who says, that we hear nothing of any invasion of the Caledonians by any such distinct people as the Picts; and he therefore concludes, as Innes had done before him, that this denomination was merely a new name, which was given to the old settlers. Upon the whole, Mr. Chalmers observes, the twenty-one British tribes, who occupied North Britain during the first century, remained for ages in their ancient settlements. Five of those tribes were subdued by the Roman arms, and civilized by the Roman arts. After the Roman abdication, these five tribes continued, in their appropriate country, on the south of the Friths, distinguished by no other circumstance than their civilization from the sixteen tribes, who equally remained unsubdued on the north of the same Friths, and who obtained the name of Picts. These were as much the descendants of the Cambro-Britons as their southern neighbours of Strathclyde, who were noticed, till recent times, as genuine Welsh.

Upon the death of Bred, the last Pictish king, A.D. 843, Kenneth, the son of Alpin, king of the Scots, obtained the Pictish government; in his person a new dynasty commenced: the king was changed, but the government remained the same. The Picts and Scots, who were a congenial people, from a common origin, and spoke cognate tongues, the British and the Gaelic, readily coalesced; and the union of the Picts with the Scots, A.D. 843, conjoined the separate dominions of both, and led on to the annexation of other territories. The Picts had been confined, for ages before that epoch, by the Forth on the south, and Drumalban on the west, and by the German ocean on the east and north. Their southern limits had been fixed at an early period by the prevalence of the Roman power. They were induced, probably by the long continuance of that power, to consolidate the distant districts of the various tribes, which had, from the earliest times, divided their country, by their spirit of independence, and enfeebled their strength, by their desires of revenge. Tradition reported, even so lately as the twelfth century, that Pictavia had been once separated into six kingdoms. But these fictitious monarchies had long ceased to exist before the memorable union of the Picts and Scots, except in the natural divisions of the country, as they had been named by a Celtic people. The Scots, at that epoch, possessed the whole western coast, from the Clyde to Loch-Toridon, with the adjacent isles. In the days of Bede, their colonies extended from the northern margin of the Clyde, along the shores of the Irish sea, far into the north: and in the course of another century, they occupied the ample extent of Argyle, from the river Clyde on the south to Loch-Ew and Loch-Maree on the north, and from the sea on the west to Drumalban on the east. Such were the dominions which the Scots brought with them, when, by overpowering the Picts, an union was effected between them, both of authority and of territories. Chalmers's Caledonia, vol. i. See SCOTLAND.

PICTS' *Wall*, in *Antiquity*, a famed piece of Roman work, begun by the emperor Adrian, A.D. 124, on the northern bounds of England, to prevent the incursions of the Picts and Scots.

At first it was made only of turf, strengthened with palisadoes, till the emperor Severus, coming in person into Britain, repaired it, as some say, with solid stone, reaching eighty miles in length, from the Irish to the German sea, through Carlisle and Newcastle; with watch-towers garrisoned, now called castle-steeds, at the distance of a mile from each other.

It does not appear, with sufficient evidence, that Severus's wall was formed of stone: Bede expresly asserts the contrary, though Spartian intimates that Severus built both a *murus*, *i. e.* a wall of stone, and a *vallum*, or a wall of turf. Bede's words are these: Severus, after several great and difficult engagements, thought it necessary to separate that part of the island which he had recovered, from the other nations that were unconquered; not with a *murus*, as some think, but with a *vallum*: now a *murus*, says he, is of stone; but a *vallum*, such as they made round a camp, to secure it against the attacks of the enemy, is made of turf, cut regularly out of the ground, and built high above ground like a wall, with the ditch before it, out of which the turf has been dug; and strong stakes of wood all along the brink. Severus, therefore, drew a great ditch, and built a strong earthen wall, fortified with several turrets from sea to sea. The learned Camden adopts this opinion; and adds, that Severus's wall is expressed by no other word than vallum, either in Antoninus or the Notitia. Camd. Brit. vol. ii. p. 1045. See AGGER.

This wall was ruined several times by the Picts, and often repaired by the Romans. At last Ætius, a Roman general, ordered it to be rebuilt of stone, about the year 420; but the Picts ruining it in the year following, it was no longer regarded but as a boundary between the two nations. The wall was eight feet thick, and twelve high from the ground: it ran on the north side of the rivers Tyne and Irthing, up and down several hills: the tract, or remains of it, are to be seen to this day in many places, both in Cumberland and Northumberland.

The inhabitants of the country pretend, that there was a brazen trumpet or pipe, so artificially laid in the wall between each castle and tower, that upon the apprehension of danger at any one place, by the founding of it, notice might be given to the next, and then to the third, &c. whence it derived the ancient name *cornage*; and in the inside a sort of fortified little town, now called Chester, the foundations of which appear, in some places, in a square form.

PICTURE, an imitation or representation by lines and colours of any natural object. Such representations are also called paintings, from the name of the art by which they are produced; which being capable of general application, and of great influence upon the mind, has, at all times, since men have cultivated their intellectual powers, been regarded with peculiar interest.

Were that art employed merely as ornamental, as the amusement of leisure time, or an agreeable source of innocent delight, we could not regard it as unworthy of attention; but when considered as an useful instrument of instruction, an universally intelligible means of communicating ideas, with all the force, the brilliancy, and sublimity of poetry, and with some advantages superior to those possessed by that divine art, it claims undoubted respect.

The well-known aphorism of Hippocrates, that "art is long, and life is short," applies to no peculiar art so well as to painting; since not only has no single man unaided been able to carry it to perfection, but in the progressive accumulation of knowledge through the lapse of ages, succeeding ones benefiting by the experience and examples of the former, no man has yet arrived at that degree of excellence in the practice of it, which a perfect union of all its principles and qualities would produce.

The power of exercising this useful and delightful art has, at all times, been slow of acquirement, as the history we have given of its progress under the article PAINTING evidently shews. It has this diversity in its growth from that of poetry; which has shone with conspicuous lustre at very early periods of human culture, whilst painting has never flourished,

flouriſhed, but in gradual advance with the general improvement of mankind; and has been truly conſpicuous only at thoſe times, when the arts of civilization have riſen to their higheſt pitch of excellence in the countries where it has been practiſed.

In no art has the profeſſor greater or more numerous difficulties to encounter than in painting: ſince he not only is under a neceſſity, equally impoſing as is the hiſtorian or the poet, of obtaining accurate ideas of the events he records, or the ſcenes he diſplays; but he has alſo to invent and perfect himſelf in the medium, or language, in which he communicates his ideas, before he proceeds to the uſe of it. This medium is utterly out of the ordinary way of human culture; and whatever may be the aids derived from the advantages we now poſſeſs, in having the experience of our predeceſſors as our guide, there muſt have been infinite difficulty in bringing it ſo near to perfection as the great maſters have done; and it has been only effected by an extremely gradual progreſs, and the union of ſucceſſive exertions operating in one continued line of action. Even now, with the works of preceding painters in our hands, the language of the art (the value and uſe of its materials) is neceſſarily, in a very great degree, new to every profeſſor who attains any tolerable degree of eminence. And though it muſt, no doubt, appear very extraordinary to thoſe who have never made the practice of painting their ſtudy, that when ſuch exemplars of art remain to us, men poſſeſſed of good ſenſe ſhould heſitate in producing the like; or that, when they are become capable of making copies, perfect almoſt to deception, they ſhould not be alſo capable of employing the means they have acquired, in a ſyſtematic mode, in works of original invention; yet the reverſe, in many inſtances, is a fact of univerſal notoriety; and proves inconteſtibly, that the art of painting, particularly when employed upon original matter, is more dependant upon mental exertion, than manual dexterity, in its execution, as well as in its object and effect; and well worthy of the rank aſſigned it by the Greeks among thoſe arts which they denominated liberal.

Notwithſtanding the high degree of perfection to which this art has been carried, no ſcientific or complete ſyſtematic arrangement has yet been adopted for the perfect guidance of the painter; nor does it appear probable that any one ever can be formed, that will effectually apply to the practice of an art ſuch as his, which is capable of ſuch an infinite diverſity of character and effect. A man of enlarged mind, carefully conſulting the pictures of preceding artiſts, cannot avoid acquiring information which may aſſiſt him in his labour; and it is by this means, more than by regular ſyſtematic inſtruction, that painting has arrived at eminence. But then, the power of extracting valuable information, and of employing it judiciouſly, even in the practical part of the art, is almoſt as rare as the ſuperior ones of invention, of compoſition, or deſign. Thus, however, as in other arts or ſciences, ſomething is ready done to the hands of the painter; he builds upon a foundation laid by his predeceſſors; but the benefit is derived principally from ſeeing what may be done, rather than in being informed how to do it. He has yet to diſcover what colours or materials will moſt effectively combine to attain his end, even in copying pictures; and when he ventures to attempt the imitation of nature, to trace her varieties and intricacies through the numberleſs paths of light and ſhade, and colour, and in all the diverſities of view in which objects preſent themſelves, then the whole value of the information obtained by the ſtudy of the works of former maſters in the practical part of the art, falls ſtill lower in the ſcale of utility, from the extreme difficulty of applying it. Perhaps there cannot be a greater proof of the originality of thought required in the mere practice of the art, than the great diverſity of the works produced in competition with old pictures, by thoſe who have at different periods admired and ſtudied them enthuſiaſtically. No man of genius, or of good ſenſe, will, however, ſlight the advantages which the ſtudy of them may afford him. He may not, at firſt, obtain the full and actual information he ſeeks, but the attempt will lead him in a right way to the diſcovery of the true principles of art; and time may be ſaved for their application, which, without ſuch helps, muſt have been loſt in experiment. Without tuition, the only mode of advancement in mental culture is by diſcovering our imperfections; a mode by no means favourable to rapid improvement, when there is nothing better than our own productions to operate as a corrective. But when good examples are before us, and our firſt object is to rival them; this advantage, at leaſt, is derived from the attempt, that we ſet forth in a road which leads to a happy termination, and have no occaſion to retrace our ſteps; like him who ſtarting without a guide, wanders in the mazes of ignorance.

If to acquire poſſeſſion of the means of the art of painting, the mere power of combining colours in ſuch a manner as to produce imitations, be thus encompaſſed with difficulties, how great is the taſk of him who undertakes to unite its higher principles with its nobleſt aims; and ſucceſsfully to apply it in extended compoſitions, illuſtrative of hiſtory, of poetry, or of philoſophy. Such has been the exalted and ſucceſsful ambition of many painters: and their works have proved the beauty, the utility, and ſublime power of the art they profeſſed, when exerciſed by genius, and applied with energy.

To effect this, the hand and the head muſt equally combine in their efforts. No vulgar or uninformed man, no one who has not taken pains to cultivate and improve his mental faculties, can be a great painter, in the exalted ſenſe in which we view it. Whatever is requiſite for the poet or the hiſtorian, in cultivation and information, ought not to be diſregarded by the painter, whoſe deſire is to exerciſe his art in an honourable or uſeful manner, as the great maſters among the ancient Greeks and in the more modern Italian ſchools have done. If it be not required of him to become as learned in natural philoſophy as Newton, he ought not to be unacquainted with its principles: his buſineſs is not merely with the ſurface of things, if he wiſhes to repreſent their appearances in a ſenſible and characteriſtic manner. A knowledge in the ſciences, ſufficient to inform him of the principles which direct and govern the actions of animals, and cauſe the various appearances of natural unanimated objects, cannot, or ought not to be unintereſting to him whoſe whole life is employed in contemplating and repreſenting their forms or their effects. If he knows the natural ſtructure of an animal, its modes and habits of life and action, he at once, and without heſitation, directs his attention to the parts moſt materially neceſſary to its delineation; and does not loſe his time, as an ignorant perſon would do, in repreſenting thoſe parts, which, though they may, from accidental cauſes, ſtrike the eye, yet are, in effect, prejudicial to true character; and if marked too ſtrongly, even with the hand of ability, counteract the effect of thoſe more efficient in general repreſentation, which always ought to be the ſole object of him who wiſhes to be a great painter. In the repreſentation of objects of unanimated nature, a juſt comprehenſion of their cauſes and effects will, in great meaſure, operate in the

ſame

ſame way. We do not mean to ſay, that if a man happens, for example, to know the cauſe of a rainbow, or can form a pleaſing theory upon it, that he will therefore be able to ſelect and blend, in a proper manner, the colouring ſubſtances neceſſary to paint one with truth and taſte: we have already ſaid that this is a matter utterly unconnected with all other ſpecies of information: but, if he add to his technical and practical acquirements the ſcientific one alluded to, he will moſt undoubtedly ſet about the taſk with leſs confuſion of mind than the moſt ingenious among thoſe who are ignorant of it; and will the more eaſily ſatisfy himſelf of the tones to be employed; and, of courſe, be more fully aſſured of its propriety when done, and know when to leave his labour with greater certainty of ſucceſs.

To this knowledge of the principles of nature, an unremitting attention to her productions is abſolutely required of the painter. To him whoſe mind is devoted to the art, no ſcene can be vacant or unintereſting; every place affords him matter of obſervation and inveſtigation. All appearances of natural objects, from the ſimpleſt to the moſt awful; all the actions of man, the varied expreſſions of his countenance, when under the influence of his paſſions; the characters of health, of age, of beauty, and even deformity, are entitled to his regard, indeed demand his cloſeſt enquiry into their moſt characteriſtic lines and effects. All the varieties of country, the characteriſtic forms of animals, trees, rocks, &c. &c. ought neceſſarily to be known to him; in fact, there is no object the obſervation of which may not, either immediately or collaterally, be uſeful to him. The trouble which attends this conſtant application of the mind, is in the end moſt highly rewarded. His ſphere of viſion is enlarged, almoſt to the creation of another ſenſe, unknown to thoſe who are uninitiated in the art, which finds continual nouriſhment in ſcenes even of apparent dulneſs and inſipidity: imagination is ſtrengthened by it, as the power of creating new images increaſes in proportion to the ſtore of ideas he acquires; and the power of invention or combination, with whatſoever degree nature may have bleſſed him, is rendered ſo much the more effective, as he is careful and active in obſervation; whereas it would be utterly uſeleſs, or worſe, if not thus ſupplied by a well digeſted maſs of materials, raiſed by continual ſtudy of nature; particularly of the beautiful, the grand, the intereſting, and the characteriſtic.

This union of general knowledge with practical ability, may be regarded as the material, or the body of the art, the ſervant of its more exalted and ſpiritual eſſence, the power of invention and expreſſion, by which alone the charm of the art is acquired and imparted. In vain may the moſt ſkilful operator combine his colours, and arrange his lines; or the moſt ſcientific compoſer determine his groups, and perfect his forms, in exact imitation of nature, if a vivid and correct invention, amply ſupplied with the ſtores of nature and of art, has not formed the baſis of the work; and if an enthuſiaſtic feeling of expreſſion does not pervade every part, and add, with its glowing energy, the true and forcible impreſſion of life, of motive, and of motion.

To this end, the nature of the ſubject is the only proper guide; the little that can be taught being quite unavailing, if not directed by feeling and the principle of the ſubject. Rules are allowed to controul in the arrangement of inferior matters; indeed it is only by ſcience, that ſcenes of common, or ſtill life, become intereſting; but whenever expreſſion, action, character, are required, when the object is, to develope ſentiment, to create emotion, or impreſs with ſublimity, the prime governing power muſt be the original impreſſion made upon the artiſt's own mind, and emanating from the ſubject; to which rules muſt be made ſubſervient, ſyſtematic arrangements muſt give way, and whatever can be ſupplied by commonplace tuition, can only be appealed to in a minor degree.

The baſis of the art of painting is imitation: its object, when it is beſt employed, is to excite emotion. The pleaſure or pain which it is capable of exciting, reſts not, however, altogether upon actual imitation; ſince all the moral purpoſes of the art may be effectually anſwered by lines only; at leaſt, all that can be imparted by the action and expreſſion of figures. (See OUTLINE.) It is ſufficient for thoſe purpoſes, that a hint intelligible to the underſtanding be given, by which the mind is filled with idea ſufficient to fix its attention. Hence ariſes the notion, which has been ſupported and oppoſed with conſiderable power by men of talents, that an union of the qualities of the different ſchools of painting would be injurious, inſtead of beneficial, to the practice and effect of the higher object of art. (See PAINTING.) It is a certain fact, and allowed by both, that too cloſe an imitation weakens the ſentiment of a picture; abſtracts the mind too much from the object to fix it upon the means; and by dividing the intereſt, diminiſhes its power. We do not mean by too cloſe an imitation, that narrow view of nature, which, without ſelection, takes men and things as they are, and copies defects and beauties with equal fidelity; but would extend it to the moſt perfect ſyſtem of combination and ſelection, unleſs wrought upon the general principles of ideal nature. (See IDEAL.) Yet it is not in the quality of the imitation the danger lies, ſo much as in the degree; and we perfectly agree with thoſe who are in favour of truth in colour and effect, as well as form: and know no reaſon why the imperfect colouring of the Florentine, or any other ſchool, ſhould be an allowed medium, through which, by incorrectneſs, the mind ſhould be made to conceive of what is right; in preference to another, which, without diſturbing the imagination by preſenting images too minutely juſt, yet has its baſis in correct imitation.

Nothing can juſtify the impropriety of attempting to make falſehood the ſource of truth. It has by no one ever yet been made apparent, that an hieroglyphic is more emphatic than a true image; and till that is done, we muſt be excuſed from believing that a falſe imitation of nature can be ſubſtituted, with equal effect, in place of a juſt one. Whatever is introduced muſt, of courſe, be ſubject to the governing principles of the art in chiaro-ſcuro and tone of colour; and alſo in the degree of imitation, or of advance towards the appearance of abſolute projection and reality; and theſe all depend entirely upon the nature of the ſubject. But what is done, ought ſurely to be founded upon the general principles of nature, and not upon a fictitious ſubſtitute, which perhaps may have originated leſs in choice than neceſſity. The limited number and kind of the colours employed in freſco, together with its peculiarities of execution, forbade, for a while, any great degree of richneſs, of brilliancy, or of truth, in colouring, but we have many ſpecimens to prove, that when more beautiful, more artful, and true colouring was effected by the uſe of oil, that the great maſters themſelves of the Florentine and Roman ſchools attempted, as far as poſſible, to impart ſomething of it to their freſcoes. Raphael's pictures of the Heliodorus and the Miracle at Bolſenna, are very ſtriking examples of this fact, that true, though general imitation, was the guide of his pencil; and ſtill more did he exhibit his ſenſe of its value in his picture of the Transfiguration; and in almoſt all his productions in that medium which permitted the attempt freely. Even M. Angelo ſought to unite the richneſs, vivacity, and reality of Titian's colouring, with his own grandeur and ſimplicity of deſign, by employing the pencil of Sebaſtian del Piombo, and others, upon his own compoſitions.

We cannot conceive that the great ſtyle of deſign may not have its appropriate tones of colour true to nature, yet ſuitable to its dignity and ſimplicity in form; and probably ſir Joſhua Reynolds and Mr. Opie, who ſtand oppoſed to each other in opinion in this matter, may not, in reality, ſo widely differ, as at firſt ſight they appear to do. The former aſſerts in his fourth diſcourſe, that "there are two ſtyles of hiſtorical painting, the grand ſtyle," (that of the Florentine ſchool,) "and the ſplendid or ornamental," (that of the Venetian); and again, "that the great ſtyle ſtands alone, and does not require, perhaps does not well admit, any addition from inferior beauties." Had he not in a former part of the ſame lecture aſſerted, "that the pictures of the Venetian ſchool were not only too brilliant, but alſo too *harmonious*, to produce that ſolidity, ſteadineſs, and ſimplicity of effect, which heroic ſubjects require," and which ſimple and grave colours only can give to a work, there would have been no reaſon to conclude from the other remark, that he thought truth of imitation, with certain limitations, inimical to that grandeur of impreſſion required: and when it is conſidered, that he is ſpeaking of the characteriſtic diſtinctions of the two ſtyles, and has previouſly declared, that he wiſhed it to be underſtood, "that in ſpeaking of the Venetian or ornamental ſtyle he excluded Titian, who had a ſort of ſenatorial dignity about him, particularly in his portraits," and meant only the works of P. Veroneſe and Tintoretto; and that, in another place, he declares it to be his opinion, that "the tone and ſtyle of colour of Ludovico Carracci is the proper vehicle for hiſtoric art," we cannot believe that his mind could be made up to the approval of the dry, hard, and imperfect management of colours exhibited in the general ſtyle of the large freſco pictures of the Florentine and Roman ſchools, when compared with the truly fine efforts of imitation by Titian, or even ſome of thoſe works themſelves more perfect in harmony, depth, brilliancy, and truth. It appears moſt probable that his ideas of diſſonancy, were principally attached to thoſe peculiarities which diſtinguiſh the ſtyles; where they turned aſide from nature, to mark more ſtrongly their peculiar objects; and which ſeparate completely and neceſſarily the ſeverity and purity required by the one, from the luxuriance and ſenſuality attached to the other.

To this opinion Mr. Opie aſſents, when he cautions the painter to "beware of loſing the terrors of the crucifixion, in the magnificence of a triumphal ſhow; or of diſturbing the pathetic ſolemnity of the laſt ſupper, with the impertinent gaiety of a bacchanalian revel;" and juſtly obſerves, that "the grand ſtyle conſiſts not in neglecting to give all the apparent truth, force, and reality of objects to the eye; but in ſupplying the defects, and avoiding the redundancies, of individual and imperfect forms;" and adds, that "colouring is not leſs capable, by rejecting what is merely accidental, and copying only the general and characteriſtic hue of each object, of being elevated to the ſame ideal ſtandard."—"One ſimple and refined principle operating equally on all parts of the art," muſt ſurely produce a correſpondent effect in all: and there is no apparent reaſon, why the ſame ſyſtem of operation, which, whilſt it elevates, ſtill maintains deſign in purity, ſhould not produce in colouring a correſpondent degree of expreſſion, of ſimplicity, and of truth; without violating harmony, or preſenting diſcordant and harſh contraſts in ſhades and colours.

We muſt again repeat, however, that the *degree* of imitation is the eſſential part for conſideration, as being that wherein the difficulty lies. If colours are to be reduced in their tones, and made ſerious in their effect, to ſuit the dignity of hiſtoric deſign, they may be reduced as twilight reduces them, in which forms and colours together are ſeen only in general maſſes. The St. Peter Martyr by Titian, is a fine exemplar of that kind of effect; grand and impoſing, yet true. Time has indeed produced ſome changes in the effect of that work, but the principle of imitation remains diſcernible to a well-informed eye, and is broad, yet juſt; ſimple, yet effective and rich. The execution of the inferior parts is not, as has been ſaid by a learned critic, (ſee Edin. Rev. Aug. 1810, art. Barry,) wrought "with all the accurate truth of a botaniſt;" and if they were ſo executed, it would, as ſir J. Reynolds has more juſtly ſaid, only be labour waſted. They have truth in character, but not minute botanical markings; and it perhaps would puzzle a botaniſt to do more than point out the genus of the plants upon the fore-ground. Nature, however, is evidently the guide, and Titian has only omitted thoſe parts which, if he had imitated them, would never have been ſeen at a proper diſtance for viewing the picture, and which being unneceſſary, muſt have diminiſhed the general intereſt if made obſervable. They are not even ſeen in nature minutely, when the eye is not immediately directed to them, but is attached to ſome peculiar object which they ſurround; and the imitation of them therefore ought to be general, as the natural impreſſion is; if it is wiſhed that the principal object ſhould remain undiſturbed in effect.

But however intereſting and agreeable, perfect and full imitation in colour, and light and ſhade may be, yet wherever it is intended to produce a great or ſublime effect, it muſt be remembered that form is the moſt effective agent which painting can employ. Sir Joſhua Reynolds, fully conſcious of its value, has ſaid that "he who is capable of delineating fine forms, even if he can do nothing more, is a great artiſt:" and in perfect conſonance with this opinion, the principal object of all the greateſt maſters has been to acquire a knowledge of the forms of natural objects, and the power of delineating them. Annibal Caracci is ſaid to have told his ſcholars, "firſt to make a good outline, and then, however the middle be filled up, it muſt be a good picture." This, however, muſt be regarded as a freedom of ſpeech, too looſe to be followed to the letter; yet it conveys his ſtrong ſenſe of the powerful neceſſity of employing ſkilful deſign,—the original foundation and the moſt uſeful principle of the art; without which, the others are completely nugatory.

This ſimple principle, which apparently offers little difficulty to be overcome, requires, nevertheleſs, the deepeſt ſtudy, and the moſt conſtant practice, in order to obtain its two moſt important requiſites,—correctneſs and expreſſion. The only mode of acquiring theſe, is derived from that general ſtudy of nature which we have ſpoken of above. No man, for inſtance, can draw the human figure in ſuch a mode, as to correſpond with either of thoſe terms, who is not well verſed in the anatomy of it; not even when it is in a tranquil ſtate: how much leſs ſo then, when it is animated and in motion; when the agitations of the paſſions extend, or contract the limbs; or the gentle ſentiments of affection cauſe them to play in graceful undulation. Without the knowledge of the ſtructure of the bones, the forms and attachments of the muſcles, and their conſequent varieties of action,

tion, he muft neceffarily confound the effential with the ufelefs; the folid, unchanging, and characteriftic forms, with the integuments that encumber them and difguife their action.

It is not, however, in outline alone, that the underftanding of form is requifite to the painter; fince in a ftyle correfpondent to the character which that poffeffes, fhould the fpace it circumfcribes be wrought by the chiaro-fcuro, which comes next in value among the principles of the art, and by which the form fuggefted to the fancy by outline is rounded, made to project from the ground, or from other forms, to obtrude itfelf upon the notice of the fpectator, or recede and fall back from the view. (See CLAIR-OBSCURE.) The paffion or the action which the drawing of the outline prefented, may be in moft cafes greatly affifted by this branch of the fcience of art; as in poetical fcenery, for inftance, and whatever depends upon illumination in tone or degree. Scenes of horror and obfcurity, which participate of the myfterious or fublime; and the enchanting bland effects of ferenity and repofe, alike find in chiaro-fcuro their main ornament and fupport; though colouring, when judicioufly applied and conducted, is that which lends the finifhed perfection of the art, and completes the degree of illufion which is its aim. See COLOURING.

The beft mode of acquiring the practical part of painting, is certainly, in the firft inftance, to copy the works of good painters, under the guidance of an able inftructor. Slight, however, in comparifon with the object, is all that tuition can afford in this matter. The arrangement of the pallette, the preparation of colours, the general principles of their union or oppofition, and confequently the order of their moft agreeable arrangements and moft powerful effects, together with the beft or readieft mode of exercifing the implements of the art, may of courfe be communicated and learnt. The mind may be directed to feek for refinement in tafte of form and colour, and to felect and combine them; but will be taught in vain, unlefs nature has implanted the feeds of difcrimination, of judgment, and of tafte itfelf. And even if fomewhat of this fhould be imbibed, vain is every effort to impart imagination, invention, or the feeling of expreffion: thefe are qualities, improvable, when poffeffed, by exercife and ftudy; but not to be created by the power of man. To thofe who poffeffing them, feel the inclination to ftudy the art of painting, we would fay,—the true mode of learning to rival the fuccefsful efforts of the great mafters, is not by copying fervilely the furfaces of their works; but when the power of execution is in part obtained, endeavour, while copying, to fearch into the principles by which compofitions are arranged, and upon which their execution is effected: wherein confift, and what are the peculiar features of colour, or of handling, that give the character of grace and tafte expreffed in them; and what peculiar traits of imagination moft beautifully and moft juftly develope their fubjects. In inveftigating pictures with views dictated by fuch defires, it will frequently be found, that what appears to fuperficial obfervers mere freaks of fancy, or mere recreation or indulgence of the pencil, is the refult of the moft deeply inventive faculty, and admitted, not for pleafure only, but for the moft important purpofes. Such, to inftance in a work open every feafon to the infpection of artifts by the liberality of the marquis of Stafford, is the little vafe in the middle of Titian's picture of the bath of Diana. To the common obferver it prefents, as intended, a proper accompaniment to the toilette of the goddefs, perhaps a veffel containing perfume, no matter whether difpofed of here or there, provided it were introduced; yet more an ornament than a neceffary adjunct in the compofition: in the eyes of the artift, it is beheld as an inftrument of ineftimable value, in preferving the brilliancy and richnefs of flefh in full, yet juft character, by its own fuperior power of reflection; and producing a brilliant focus to the light of the picture, without attracting the eye too powerfully to itfelf; not to fpeak of its interrupting, by its beautiful form, the too great regularity of the mafs of ftone-work on which it ftands. It fhould never be forgot, that painting is more a work of the mind, than of the hand; it is the former which creates, the latter only difplays; and though the art confifts, abfolutely fpeaking, in that difplay, its value is nothing, if not fupplied with well felected, well arranged materials; and is comparatively of eafy acquirement, as is teftified by every day's experience. We muft not be thought to undervalue the benefit of copying. It feems almoft abfolutely neceffary, under judicious management, to perfect the hand, and fhorten the labour neceffary for acquiring the practical part of the art, and therefore the more early in life it is begun the better; and if, while the hand is engaged in the labour of it, the mind be employed in developing the principles upon which the work is conducted, then there is the chance of advantage being derived from the neceffity of devoting fo much time to one object; as it affords the opportunity of deeper and more folid inveftigation. One thing is certain, that there is no mode of obtaining excellence in painting but by a regular and fteady purfuit. Let the original foundation of genius and talent be as good as it may, nothing fhort of perfevering induftry can raife the fuperftructure. "There is no royal road to the arts," no fhort cut whereby the painter may arrive at the end of his courfe, and efcape the labours of ftudy and exercife; and of this the practice and declarations of the very greateft artifts are fatisfactory proofs. Apelles, it is faid, never allowed a day to pafs without exercifing his art in a greater or lefs degree. The induftrious exertions of the moft able of the Italian artifts are on record: and our own great example, fir Jofhua Reynolds, is a hoft in himfelf: the immenfe quantity of his works amply teftifying his induftry, as well as his attachment to the art. Indeed, without that entire devotednefs which fuperfedes, though it does not exclude, all attention to other objects, it is impoffible to obtain that facility of hand, or intelligence of mind, which reforts to the proper fources for a fupply of materials to fill the canvas, to improve or embellifh a compofition, to fupply deficiencies or correct defects, by a prompt and happy recollection of the moft appropriate objects in form or colour.

The power of execution in painting being fecured, the next ftep is to invent compofitions, and execute the parts from nature; combining them with the principles of the art. Then comes the proof, whether the ftudent has felt in his previous ftudies like an artift, or only as a man poffeffing no higher qualifications for his profeffion, than thofe with which his fellow mortals in general are endowed. Our exhibitions inform us too frequently of the mifguided hopes and labours of numerous claffes; and gratify us but rarely with any profpect of future excellence or originality; manifefting, by the woeful difappointment and ruin of hundreds, the rarity of the peculiar talent which leads to perfection in painting, and the difficulty of attaining any great degree towards that point, even by thofe endowed with tafte and fenfe to feel and practife the art with great ingenuity.

It is an advantage to thofe who are fo favoured, if they endeavour to look forward beyond the fkill exhibited by others.

others, and aim at improving even upon the practice of their predeceffors. They at leaft who hold this courfe are more likely to do fomething meritorious than others, who fear to launch out of the beaten track: and if their works are conducted upon found principles, with elevated ideas, and freedom in execution, though they may fail to obtain the object of their wifhes; yet they have the beft chance of foaring above mediocrity, and the moft reafonable ground to hope for applaufe.

There is, however, a danger attending this ambitious adventure; it is that of miftaking novelty for improvement; of fubftituting the rafhnefs of a licentious imagination, for the corrected and chafte effufion of true well-founded feeling and judgment. Unfortunately we have too frequent reafon to regret, that a man may poffefs great vigour of fancy, unaccompanied by found judgment; the want of the latter rendering abortive the vivacity and brilliancy of the former. There are none who are more in need of the corrective hand of a mafter, than a youth whofe imagination outftrips his reafon: and it not unfrequently occurs in the practice of the art, that the flow but fteady growth of one endowed with a capacity little above the common ftandard, furpaffes in the end the precocity of the former; who, indulging his imagination, plays with the ftore of knowledge early tuition has fupplied, and forgets that the only mode of maintaining the fancy in full force, is by fupplying it with new images; which perpetual recurrence to nature only can produce, and perpetual practice only can fecure. "Invention," it has been faid, "is not creation;" therefore to be a good and ingenious inventor in art, is not to run far into the riot of fancy, by the mere indulgence of it in wanton and monftrous devices; but rather to bring together fuch combinations of natural objects in their pureft forms, as will beft illuftrate the fubject adopted. This is its regulator in the higher clafs of pictures; in others of a lower order, and particularly what is called ornamental paintings, falfe and heterogeneous combinations, beginning at firft in allegory, and afterwards continued, in fpite of their acknowledged abfurdity, merely on account of their beauty of form, allow of all the loofe indulgence of the fancy which the moft vivacious can defire.

When we confider the general extent of the gratification and information afforded by painting, it is extraordinary that a due attention to its principles is not yet admitted as a portion of polite education; fince the knowledge of them fo evidently increafes the pleafure the art is capable of producing: the more particularly when, among the higher claffes of mankind, it forms fo very conftant and material a fource of their delights, and is fo conftantly alfo a fubject of difcuffion, although arifing from, and pretty generally decided by, fenfation, rather than reafon; and neceffarily fo indeed! "What can we reafon, but from what we know?" Pope has juftly faid, and how can they decide with reafon upon the merits of a work, who are ignorant of the principles upon which it is conftructed? Yet fo much of it is felt to be defirable, that every gentleman and lady conceives it neceffary to learn to draw, regarding the art as worthy of a partial devotion of time: but this is generally effected in fo inferior a degree, as to leave the polifhed learner utterly uninformed of its higher claims, its worthier objects, and its real utility.

To be truly a connoiffeur or a judge of the qualities of painting when exercifed in its higheft ftyle, notwithftanding the impertinent flippancy of thoufands of pretenders, requires a peculiar cultivation of mind; quite as much fo as any other art or fcience requires an initiation into its principles, to be a judge of its effects. Our art, however, appealing to the fenfe of fight, more than to reafon, and producing its effects from the reprefentation of well known objects, has a great advantage over others, in that its end is more eafily comprehended, although the principles which govern its practice are not lefs abftrufe and difficult of application. Moft men, therefore, of good mental capacities, are capable of underftanding and feeling the grand and general points; fuch as of colour, whether it be like that of natural objects, under peculiar circumftances; of expreffion, and if the ftory be fully and clearly exhibited; and of the general effect of the chiaro-fcuro, whether it prefent an agreeable furface to the eye, &c.; but of the fubtleties of arrangement and execution, whereby difficulties arifing from the nature and difunion of the materials and parts are overcome; of the delicate hues, which are covertly introduced to produce harmony; and of the art which attaches light to light, and dark to dark, to produce maffes, without violating the principles of nature: of thefe things, hidden as they are in the myftery of the art, none but an artift can well judge; though a portion of that knowledge may be acquired by fcientific ftudy without practice. No doubt a man being conftantly or frequently in the habit of comparing picture with picture, and both with nature; and reflecting upon the diverfities of each, their beauties, and their defects; may acquire a very confiderable power of difcrimination and judgment in matters of art; and more particularly if he devotes that time, which the regular artift is obliged to employ at his eafel, to a careful inveftigation of nature, and the ftudy of the means and principles of art. A man fo tutored may become able to guide, in many points, the pencil of a good painter: ftill there are many others to which his attention can never be attracted, as they arife only from practice, and confequently can only be known and appreciated by thofe who are engaged in it. Thefe, it may be remarked, muft be of an inferior nature; and true it is they are fo, in comparifon with the great leading and effential features of a picture, whofe fubject is of a grand and heroic character; but neverthelefs they enter into the aggregate, and affift in affording delight to that organ of fenfe through which the art appeals to the mind, and more readily enable it to attract attention.

This valuable art has, in the courfe of the world, been generally regarded as worthy of the greateft honours; and its eminent profeffors of a proportional fhare of eftimation and rewards. Some of the greateft among men have, at different periods, upheld this opinion of its excellence, as its hiftory teftifies (fee PAINTING); but Pericles, at the head of the Athenian republic, was the firft who duly eftimated its value as a national political inftrument; and encouraging it, in conjunction with fculpture and architecture, laid, in part, the bafis of the long continued fame of the city. He fatisfied the people, who murmured at the expence he indulged in in the public works, that by advancing the interefts of the arts, he was promoting their own glory. In tracing the mode in which they were employed, we difcover the principles upon which they act; and which, being founded upon feelings and fentiments of the human heart, muft always produce the fame effect.

It is doubtlefs to the direction in which talent is employed, that we owe its utility, or its power to do mifchief. The love of fame was the firft object of the Greeks, and their leaders therefore very wifely employed every means to maintain fo ufeful a fpirit. In compliance with this, Panænus and Polygnotus were employed by Pericles to adorn the public buildings with paintings, the fubjects of which were the heroic actions of the moft renowned among their countrymen;

trymen; thus perpetuating a record of thofe deeds which excited to emulation, which, appealing to the natural and inftinctive pride of man, in a becoming manner, neceffarily leads, wherever it is ftrongly felt, to great and ufeful conduct. There is no denying that painting is peculiarly adapted to this fpecies of excitement, its effect being full and inftantaneous; as the impreffion made upon the mind by witneffing the exhibition of a fcene of heroifm, of diftrefs, or of delight, is greater than any which can arife from a detail of it in defcription. The intereft in the relation is the weaker, as impreffion fucceeds to impreffion; whereas in the fact, or the reprefentation of it, the whole rufhes upon the fight at once. But then it muft be acknowledged, that there is this drawback in its effect upon the minds of men in general, that they are not prepared to comprehend more than the general impreffion; therefore the public works of the Greeks in painting, appear to have been conducted upon the moft fimple principles, in order that their whole object and intention might be univerfally embraced.

It is fcarcely credible that, in direct oppofition to this fentiment of the Greeks, any one fhould affert, in this enlightened period, that no inculcation of moral or religious truth can be effected by painting; the more fo, when the works of Hogarth, the moft inftructive of painters, are in our hands, and no one who ever thinks of art at all can plead ignorance of them. An affertion to that effect has, however, lately been made by a very learned and ingenious author, in a critique on the life and works of J. Barry, efq. (fee Edinb. Review, Auguft 1810,) and he has gone the length of faying, "that as to conveying moral, religious, or political inftruction in pictures, it is the moft abfurd of all abfurd notions." If the ingenious gentleman means, by the word inftruction, that kind only which properly belongs to painting, and to which, when fpeaking of the art, (if he mean well to its caufe,) he ought to confine himfelf, *viz.* that fudden and unavoidable impreffions of truth, which moft men, not utterly deftitute of fenfe, receive upon the firft fight of a well regulated moral, or poetical compofition; more particularly fuch as, being drawn from common nature, applies common objects to its purpofe, and prefents to the obferver familiar incidents, furely every day's experience is againft him. We would appeal to himfelf, if he has never received the impreffion of difguft at pride; abhorrence of avarice and of fenfuality; difdain of vanity and idle wafte of time, a prudential hint of the folly of extravagance, and of trufting to gay diffipation for the enjoyment of happinefs; from the feries of pictures called The Marriage-a-la-mode by Hogarth. What moral lectures in rhetoric would, or could, more completely illuftrate, in a more univerfally intelligible manner, the fatal effects of vice, or the beneficial ones attendant upon virtue, than that ingenious painter has done in this, and others of his productions; as the induftrious and idle apprentices, the Rake's and the Harlot's progrefs, &c. &c.; and yet with thefe defigns in his hand, has he rifked fo unjuft and ungenerous a fentiment as his affertion conveys. Ungenerous, becaufe, if true, it can be productive of no good to extend fuch an opinion, and it tends to diminifh the regard which painting has defervedly received from the world, wherever its higheft powers have been engaged; and unjuft, becaufe it is contrary to the acknowledgment of ages, and is upheld by no reafoning at all applicable, and fcarcely tangible; fince, in fupport of it, he only inquires with a fneer, "what *argument* can be drawn in fupport of the idea of a future ftate, from Mr. Barry's picture of final retribution?" Does he not, in this, miftake the ground on which he ought to reafon upon painting? If, by argument, he means its ufual acceptation, a deduction from point to point, till we arrive at a fatisfactory definition of what is virtue and religion, or what is the probable nature of that future ftate of exiftence which man is deftined to partake of: then we anfwer, that no *argument* in proof is expected from the art, none defired of it. The painter's bufinefs was to make that future ftate, the belief of which was already fettled, as engaging as poffible; to exemplify it in an attractive manner, and make beholders anxious to participate in its glory; and the enquiry ought to have been, has Mr. Barry effected that purpofe? We do not hefitate to fay, that in the point of invention he undoubtedly has. Who, beholding the affemblage of illuftrious characters which he has introduced in that picture, upon a moft judicious ground of reafoning, *viz.* their ufefulnefs to mankind, is not led to ferious reflection, and an ardent wifh to unite with them, to be ranked with the great and good, and emulous to merit fuch exaltation; to fhare their converfation; to receive their inftruction; and to adore in their enlightened fociety, that beneficent Creator whofe incomprehenfible greatnefs and goodnefs made and fuftains the univerfe. Such was, fuch alone could be, the juft object of the painter; and no attempt to prove the fact, whether this "corruptible fhall put on incorruptible" or not; for that the Chriftian reforts to his Teftament, and the heathen and the philofopher to nature. The artift can only exemplify it, and enlarge our confideration of that ftate wherein rational beings may be fuppofed to enjoy the higheft poffible degree of felicity; and in this refpect Mr. Barry is borne out in the opinion he has endeavoured to illuftrate, by the writings of many ingenious divines.

To fay, what indeed is not faid, but muft almoft neceffarily be inferred, that no impreffion could be made upon the mind of an obferver, favourable to virtue and religion by the contemplation of that picture, would be to fay, that he either was incapable of reflection, or that by vice and fenfuality he was become ill fitted to receive fuch impreffions as it is calculated to produce upon well regulated minds; common experience is againft it, and hundreds have left the room where it hangs with as ferious and ufeful emotions, as a fermon on the fubject would produce. Many have expreffed thefe fentiments to the writer of this article; and he himfelf takes his opportunity of paying a grateful tribute of refpect to the memory of Mr. Barry, whilft he acknowledges the lafting impreffion it made upon his mind, when he faw it in early life. Thus although the avowed truifm, that virtuous conduct is the wifeft and beft that man can purfue for his own happinefs, will find no *argument* in the pencil for its fupport; it will have a moft able affiftant, by the exhibition it is capable of affording of its effects. Is the moral or religious effect of painting, when duly appreciated and exercifed, to be denied, when, as we have ftated, fuch works as Hogarth's exift? and is that to take place firft of all in the country where he was born, and exerted his ufeful talents?—He, whofe pencil inculcates fo powerfully the value of good, and the enormity of evil, and by the reprefentation of the common events of life, brings home the fentiments of morality to every mind, and makes fo forcible an appeal to the heart and head of every man poffeffed of ordinary underftanding, be his ftate in life what it may; not, we will venture to fay, to the exception of the learned author himfelf, whofe ungentle fentiment towards the art is the caufe of thefe remarks;—a fentiment whofe object, or whofe effect at leaft, if it have any, can only be to reftrict the pencil from its moft honourable and moft valuable application; and render it a mere inftrument of amufement, or of idle and ufelefs gratification, or worfe.

The appeal of the pencil is not fo much to the underftanding, as to the heart and mind; by that the firft excitement is produced, and thence neceffarily follow reflections, attached to the nature of the images prefented to the eye. Do we not fearfully acknowledge its power to corrupt young minds, and take conftant care to keep improper drawings from their view? What mode of information does it purfue in this cafe, but that of prefenting images of agreeable vices in an engaging manner? And is it allowed to be fo fufficiently potent for the production of evil, that all our care is requifite to counteract or prevent its influence in that refpect, and fhall it be denied any influence in the promotion of good! forbid it reafon, fenfe, and juftice! If the objection to its utility be juft, how fhall we eftimate the wifdom of thofe whom the learned author alluded to fufficiently honours on other occafions; of thofe who employed fculpture and painting as political and religious agents, to ftimulate the ardent minds of the Greeks to heroifm or devotion. The opinions of almoft all ancient authors who have noticed it, are moft decidedly in favour of the utility of the pencil; and thofe of the wifeft politicians among the moderns have been amply illuftrated by the ufe they have made of its powers.

If any thing can moft effectively contribute to ftrengthen the difinclination of the government of our own country, towards the employment of painting in a way more worthy of its powers than portraiture, it is remarks of this nature, originating with men of acknowledged talent, of great acquirements, and partial devotion to the arts; and which, while they are fo guarded as to be capable of juftification in their author's peculiar view; yet leave an impreffion on the reader, much more widely effective in preventing or deftroying the energies of the art, than he perhaps intended. But Dr. Johnfon is reported to have faid, that "he never could fee any connection between the hiftorical relation of a fact, and a picture of it;" and perhaps the author alluded to may have fome fimilar diverfity from the majority of mankind with regard to moral culture, which prevents him from regarding pictures in a moral or inftructive point of view.

Picture, *Pictura,* a piece of painting, or a fubject reprefented in colours, on canvas, wood, or the like; and inclofed in a frame.

Pictures or paintings in oil are preferved by coating them with fome tranfparent and hard fubftance, as a varnifh, in order to fecure the colours from the injuries of the air or moifture; and to defend the furfaces from fcratches or any damages the painting might receive from flight violence. The fubftances that have been, or may be ufed for this purpofe, are gum arabic, diffolved in water, with the addition of fugar or fugar-candy, to prevent its cracking; glair or whites of eggs, mixed with a little brandy or fpirit of wine, in order to make it work more freely, and a lump of fugar to prevent its cracking; ifinglafs-fize, ufed as either of the former, or mixed with a fourth or fifth of its weight of honey or fugar, and varnifhes formed of gum refins diffolved in fpirit of wine, or oil of turpentine, which laft are called oil-varnifhes.

Paintings in miniature are preferved by plates of glafs, or the talc called ifinglafs, placed before them in the frame. Paintings in diftemper may be rendered more durable, and preferved from foulnefs by varnifhing them with hot fize, boiled to a ftrong confiftence, in which a fifteenth or twentieth part of honey has been diffolved. Crayons muft be preferved in the fame manner with paintings in water colours, by plates of glafs or ifinglafs.

When pictures are cut or torn, they may be repaired by laying them on an even board or table, carefully putting together the torn or divided parts with colour laid as a cement, in and over the joint, and keeping them in the fituation till the cement is thoroughly dried. The protuberance of the cement may be eafily reduced with a penknife, and the repaired part properly coloured fo as to correfpond with the picture. When part of the cloth is deftroyed, a piece of canvas fomewhat bigger than the vacant fpace is to be plaftered over on the outfide of the cloth with white or any other colour, and when it is thoroughly dry, the inequality of the picture in this part is to be filled up with the fame matter, and properly reduced and coloured.

The art of cleaning pictures and paintings is of great confequence in order to their prefervation: in this operation great fkill and care are requifite, fo that the menftruum ufed for taking off any foulnefs may not diffolve the oil in the painting itfelf, or diforder its colours, and that each fort of varnifh with which paintings are coloured may be taken off without injury to the painting. The firft and moft general fubftance ufed for cleaning pictures is water, which will remove any foulnefs arifing from many kinds of glutinous bodies, as fugar, honey, glue, &c. and any varnifh of gum arabic, glair of eggs or ifinglafs, without affecting the oil that holds the colours together. Olive oil or butter will diffolve pitch, refin, and other fubftances of a like kind, without injuring the oil of the painting. Pearl-afhes, diffolved in water, form a proper menftruum for moft kinds of matter that foul paintings; but they muft be very cautioufly ufed, as they will corrode the oil of the painting, if there be no varnifh of the gum refins over it. Soap is of the fame nature, and fhould be cautioufly applied, and only to particular fpots, that elude all other methods. Spirit of wine will diffolve all the gums and gum refins, except gum arabic, and is therefore very neceffary for taking off from pictures varnifhes compofed of fuch fubftances, but it alfo corrodes the oil of the painting. This is alfo the cafe with oil of turpentine, and effence of lemon, fpirit of lavender, and rofemary, and other effential oils. With regard to paintings that are varnifhed with gum arabic, glair of eggs, or ifinglafs, the varnifh fhould be taken off when they are to be cleaned. This may be eafily diftinguifhed by wetting any part of the painting, which will feel clammy, if varnifhed with any fubftance foluble in water. This kind of varnifh may be taken off with hot water and a fpunge, or by gentle rubbing with a linen cloth dipped in warm water. If paintings, on this trial, appear to be varnifhed with gum refins, or fuch fubftances as cannot be diffolved in water, they may, in fome cafes, be fufficiently cleaned by a fpunge with warm water; and any remaining foulnefs may be removed by rubbing the painting over with olive oil made warm, or with butter, which fhould be wiped off with a woollen cloth; and if the picture require farther cleaning, wood-afhes or pearl-afhes may be ufed in the following manner: take an ounce of pearl-afhes, and diffolve them in a pint of water; or take two pounds of wood-afhes, and ftir them well in three quarts of water, once or twice in an hour for half a day. Then pour off the clear fluid, and evaporate it to a quart or three pints; wafh the painting well with a fpunge dipped in either of thefe leys, and rub gently any foul fpots with a linen cloth till they difappear. If this method fail, recourfe muft be had firft to fpirit of wine, then to oil of turpentine, and if thefe are ineffectual, the effence of lemons; with either of which the foul fpots fhould be flightly moiftened, and the part immediately rubbed gently with a linen cloth. After a little rubbing, if oil of turpentine or effence of lemon has been applied, olive oil fhould be put upon the fpot;

ſpot; and water, if ſpirit of wine has been uſed; which ſhould be taken off with a woollen cloth; repeating the operation till the foulneſs be removed. When paintings appear to have been varniſhed with thoſe ſubſtances that will not diſſolve in water, and after the uſe of the above means retain their foulneſs, the following method will ſucceed: place the picture or painting in a horizontal ſituation; and moiſten, or rather flood, by means of a ſpunge, the ſurface with very ſtrong rectified ſpirit of wine: keep the painting thus moiſtened, by adding freſh quantities of the ſpirit, for ſome minutes; then flood the whole ſurface copiouſly with cold water; waſh off the whole without rubbing; and when the painting is dry, repeat the operation till the whole varniſh is taken off. Handm. to the Arts, vol. i. p. 224. 245.

Pictures, or *Paintings, in Oil, Method of taking off*, &c. The art of removing paintings in oil, from the cloth or wood on which they are originally done, and transferring them to new grounds of either kinds of ſubſtance, is of great uſe. For thoſe on cloth or canvas, the method is as follows: let the decayed picture be cleanſed of all greaſe that may be on its ſurface, by rubbing it very gently with crumb of ſtale bread, and then wiping it with a very fine ſoft linen cloth. It muſt then be laid, with the face downwards, on a ſmooth table covered with fan-paper, or the India-paper; and the cloth on the reverſe muſt be well ſoaked with boiling water, ſpread upon it with a ſponge, till it appears perfectly ſoft and pliable. Turn the picture with the face upwards, and having ſtretched it evenly on the table, pin it down with nails at the edges. Having melted a quantity of glue and ſtrained it through a flannel cloth, ſpread part of it, when a little ſtiffened, on a linen cloth of the ſize of the painting, and when this is ſet and dry, lay another coat over it; when this becomes ſtiff, ſpread ſome of the glue, moderately heated, over the face of the picture, and lay over it the linen cloth already prepared in the moſt even manner, and nail it down to the picture and table. Then expoſe the whole apparatus to the heat of the ſun, in a place where it may be ſecured from rain, till the glue be perfectly dry and hard; when this is the caſe, remove the picture and linen cloth from the table. Turn the picture with the face downwards, and let it be ſtretched and nailed to the table as before; then raiſe round its edge a border of wax, as in the etching of copper-plates, forming a kind of ſhallow trough with the ſurface of the picture; into which pour a proper corroding fluid, as oil of vitriol, aqua fortis, or ſpirit of ſalt, but the laſt is to be preferred: dilute either of theſe with water to ſuch a degree, determined by previous trials, that they may deſtroy the threads of the original canvas or cloth of the picture, without diſcolouring it. When the corroding fluid has anſwered this purpoſe, drain it off through a paſſage made at one end of the border of wax, and waſh away the remaining part by repeatedly pouring quantities of freſh water on the cloth. The threads of the cloth muſt be then carefully picked out till the whole be taken away. The reverſe ſurface of the painting, being thus wholly freed from the old cloth, muſt be well waſhed with water by means of a ſponge, and left to dry. In the mean time prepare a new piece of canvas of the ſize of the painting; and having ſpread ſome hot glue, purified as before, and melted with a little brandy or ſpirit of wine over the reverſe of the painting, lay the new canvas evenly upon it while the glue is hot, and compreſs them together with thick plates of lead or flat pieces of poliſhed marble. When the glue is ſet, remove theſe weights, let the cloth remain till the glue is become perfectly dry and hard. Then the whole muſt be again turned with the other ſide upwards, and the border of wax being replaced, the linen cloth on the face of the painting muſt be deſtroyed by means of the corroding fluid; particular care is neceſſary in this part of the operation; becauſe the face of the painting is defended only by the coat of glue which cemented the linen cloth to it. The painting muſt then be freed from the glue by waſhing it with hot water, ſpread and rubbed on the ſurface by a ſponge. The painting may afterwards be varniſhed as a new picture; and if the operation be well conducted, it will be transferred to the new cloth in a perfect ſtate.

When the painting is originally on wood, it muſt firſt be detached from the ceiling or wainſcot where it was fixed; and the ſurface of it covered with a linen cloth, cemented to it by means of glue, as already directed. A proper table being then provided, and overſpread with a blanket, or thinner woollen cloth, laid on in ſeveral doubles; the painting muſt be laid upon it with the face downwards, and fixed ſteady; and the board or wood on which it was done muſt be planed away, till the ſhell remains as thin as it can be made, without damaging the paint under it. The proceſs is afterwards the ſame as that in the caſe of paintings on canvas, till the painting on wood be in like manner transferred to a cloth or canvas. Doſſie's Handm. to the Arts, vol. ii. p. 417, &c.

Picture, *Magical*. See Magical.

PICTURESQUE Beauty, according to a late elegant writer, refers to "ſuch beautiful objects as are ſuited to the pencil." This epithet is chiefly applied to the works of nature, though it will often apply to works of art alſo. Thoſe objects are moſt properly denominated picturesque, which are diſpoſed by the hand of nature with a mixture of *varied rudeneſs*, *ſimplicity*, and *grandeur*. A plain neat garden with little variation in its plan, and no ſtriking grandeur in its poſition, diſplays too much of art, deſign, and uniformity, to be called picturesque. "The idea of *neat* and *ſmooth* (ſays Mr. Gilpin), inſtead of being picturesque, in fact diſqualify the object in which they reſide from any pretenſions to picturesque beauty. Nay, farther, we do not ſcruple to aſſert, that roughneſs forms the moſt eſſential point of difference between the beautiful and the picturesque; as it ſeems to be that particular quality which makes objects chiefly pleaſing in painting. I uſe the general term *roughneſs*; but, properly ſpeaking, roughneſs relates only to the ſurfaces of bodies: when we ſpeak of their delineation, we uſe the word *ruggedneſs*. Both ideas, however, equally enter into the picturesque, and both are obſervable in the ſmaller as well as in the larger parts of nature; in the outline and bark of a tree, as in the rude ſummits and craggy ſides of a mountain.

"Let us then examine our theory by an appeal to experience, and try how far theſe qualities enter into the idea of picturesque beauty, and how far they mark that difference among objects which is the ground of our inquiry.

"A piece of Palladian architecture may be elegant in the laſt degree; the proportion of its parts, the propriety of its ornaments, and the ſymmetry of the whole, may be highly pleaſing; but if we introduce it in a picture, it immediately becomes a formal object, and ceaſes to pleaſe. Should we wiſh to give it picturesque beauty, we muſt uſe the mallet inſtead of the chiſſel; we muſt beat down one-half of it, deface the other, and throw the mutilated members around in heaps; in ſhort, from a ſmooth building we muſt turn it into a rough ruin. No painter who had the choice of the two objects would heſitate a moment.

"Again, why does an elegant piece of garden-ground make no figure on canvas? The ſhape is pleaſing, the combination of the objects harmonious, and the winding of the walk

walk in the very line of beauty. All this is true; but the ſmoothneſs of the whole, though right and as it ſhould be in nature, offends in picture. Turn the lawn into a piece of broken ground, plant rugged oaks inſtead of flowering ſhrubs, break the edges of the walk, give it the rudeneſs of a road, mark it with wheel tracks, and ſcatter around a few ſtones and bruſhwood: in a word, inſtead of making the whole ſmooth, make it rough, and you make it alſo picturesque. All the other ingredients of beauty it already poſſeſſed." On the whole, picturesque compoſition conſiſts in uniting in one whole, a variety of parts, and theſe parts can only be obtained from rough objects.

It is poſſible, therefore, to find picturesque objects among works of art, and it is poſſible to make objects ſo; but the grand ſcene of picturesque beauty is nature in all its original variety, and in all its irregular grandeur. "We ſeek it (ſays our author) among all the ingredients of landſcape, trees, rocks, broken grounds, woods, rivers, lakes, plains, valleys, mountains, and diſtances. Theſe objects in themſelves produce infinite variety; no two rocks or trees are exactly the ſame; they are varied a ſecond time by combination; and almoſt as much a third time by different lights and ſhades and other aerial effects. Sometimes we find among them the exhibition of a whole, but oftener we find only beautiful parts."

Sublimity or grandeur alone cannot make an object picturesque: for, as our author remarks, "however grand the mountain or the rock may be, it has no claim to this epithet, unleſs its form, its colour, or its accompaniments, have ſome degree of beauty. Nothing can be more ſublime than the ocean; but wholly unaccompanied, it has little of the picturesque. When we talk, therefore, of a ſublime object, we always underſtand that it is alſo beautiful; and we call it ſublime or beautiful only as the ideas of ſublimity or ſimple beauty prevail. But it is not only the form and the compoſition of the objects of landſcape which the picturesque eye examines, it connects them with the atmoſphere, and ſeeks for all thoſe various effects which are produced from that vaſt and wonderful ſtorehouſe of nature. Nor is there in travelling a greater pleaſure than when a ſcene of grandeur burſts unexpectedly upon the eye, accompanied with ſome accidental circumſtance of the atmoſphere which harmonizes with it, and gives it double value."

There are few places ſo barren as to afford no picturesque ſcence.

"——————Believe the muſe,
She does not know that inauſpicious ſpot
Where beauty is thus niggard of her ſtore.
Believe the muſe, through this terreſtrial waſte
The ſeeds of grace are ſown, profuſely ſown,
Even where we leaſt may hope."

Mr. Gilpin mentions the great military road between Newcaſtle and Carliſle as the moſt barren tract of country in England; and yet there, he ſays, there is "always ſomething to amuſe the eye. The interchangeable patches of heath and green-ſward make an agreeable variety. Often, too, on theſe vaſt tracts of interſecting grounds we ſee beautiful lights, ſoftening off along the ſides of hills; and often we ſee them adorned with cattle, flocks of ſheep, heath-cocks, grous, plover, and flights of other wild-fowl. A group of cattle ſtanding in the ſhade on the edge of a dark hill, and relieved by a lighter diſtance beyond them, will often make a complete picture without any other accompaniment. In many other ſituations alſo we find them wonderfully pleaſing, and capable of making pictures amidſt all the deficiencies of landſcape. Even a winding road itſelf is an object of beauty; while the richneſs of the heath on each ſide, with the little hillocks and crumbling earth, give many an excellent leſſon for a fore-ground. When we have no opportunity of examining the grand ſcenery of nature, we have every where at leaſt the means of obſerving with what a multiplicity of parts, and yet with what general ſimplicity, ſhe covers every ſurface.

"But if we let the imagination looſe, even ſcenes like theſe adminiſter great amuſement. The imagination can plant hills; can form rivers and lakes in valleys; can build caſtles and abbeys; and if it find no other amuſement, can dilate itſelf in vaſt ideas of ſpace."

Mr. Gilpin, after deſcribing ſuch objects as may be called picturesque, proceeds to conſider their ſources of amuſement. We cannot follow our ingenious author through the whole of this conſideration, and ſhall therefore finiſh our article with a ſhort quotation from the beginning of it. "We might begin," ſays he, "in moral ſtyle, and conſider the objects of nature in a higher light than merely as amuſement. We might obſerve, that a ſearch after beauty ſhould naturally lead the mind to the great origin of all beauty; to the

"——— firſt good, firſt perfect, and firſt fair."

But though in the theory this ſeems a natural climax, we inſiſt the leſs upon it, as in fact we have ſcarce ground to hope that every admirer of picturesque beauty is an admirer alſo of the beauty of virtue, and that every lover of nature reflects, that

"Nature is but a name for an *effect*,
Whoſe *cauſe* is God."

If, however, the admirer of nature can turn his amuſements to a higher purpoſe; if its great ſcenes can inſpire him with religious awe, or its tranquil ſcenes with that complacency of mind which is ſo nearly allied to benevolence, it is certainly the better. "Apponat lucro." It is ſo much into the bargain; for we dare not promiſe him more from picturesque travel than a rational and agreeable amuſement. Yet even this may be of ſome uſe in an age teeming with licentious pleaſure; and may in this light at leaſt be conſidered as having a moral tendency."

PICUCULI *de Cayenne*, in *Ornithology*. See GRACULA *Cayennenſis*

PICUIPINIMA. See COLUMBA *Paſſerina*.

PICUS, in *Ornithology*, a genus of birds of the order Picæ; the generic character is as follows: bill angular, ſtraight, wedged at the tip; noſtrils covered with recumbent ſetaceous feathers; tongue round, worm-ſhaped, very long, bony, miſſile, daggered, beſet at the point with briſtles bent back; it has ten tail-feathers, which are hard, rigid, and pointed; the feet are formed for climbing. The birds of this genus live principally upon inſects, to obtain which they climb trees, and are perpetually in ſearch of thoſe crevices in which their food is lodged. Theſe inſects they transfix with their miſſile and daggered tongue, which, when it has obtained its purpoſe, is, by an almoſt inviſible motion, withdrawn wholly into the mouth. This proceſs is almoſt inceſſantly repeated throughout the whole day, with the utmoſt preciſion and celerity. Doomed to this perpetual occupation, wood-peckers avoid ſociety, even that of their own ſpecies, and appear to poſſeſs none of the animation of cheerfulneſs, or vigour of courage. They have no notes but ſuch as are expreſſive of pain and ſadneſs, and they ſeem to lead a life of labour and reſtleſsneſs. There are nearly ſixty ſpecies mentioned in Gmelin's laſt edition of Linnæus.

Species.

* MARTIUS, or Great black Wood-pecker. The fpecific character is black; cap vermilion. This bird inhabits many parts of Europe, as well as our own country; it is alfo a native in Siberia and Chili; it is found chiefly in the poplar tree; it builds a large deep neft, and lays two or three eggs; it feeds principally on bees and ants, and is about feventeen or eighteen inches long. This bird fpeedily excavates trees, fo as to expofe them to be blown down by winds which would not otherwife have affected them. Under the hole made by it, faw-duft and pieces of wood may fometimes be found in pecks.

LIGNARIUS; White-bellied Wood-pecker. Cap vermilion; body barred with white. This is found chiefly in Chili, and is fomewhat lefs than a blackbird.

PRINCIPALIS; White-billed Wood-pecker. Black; creft fcarlet; a line on each fide the neck and fecondary quill-feathers is white. It inhabits America, from New Jerfey to Brazil; is about fixteen inches long, and makes fpiral holes in the trees.

PILEATUS; Pileated Wood-pecker. Black; creft red, temples and wings fpotted with white. It inhabits the woods of North America, and is eighteen inches long; the female of this fpecies has a brown front. There is a variety of which the belly is obfcurely barred with white.

LINEATUS; Lineated Wood-pecker. This fpecies is black; creft is fcarlet; it has a white line from the bill down the neck, and as far as the middle of the back. It inhabits Cayenne, as does the next, and is nearly fourteen inches long.

RUBRICOLLIS; Red-necked Wood-pecker. Brown, beneath tawny; crefted head and neck blood-red.

MELANOLEUCOS; Buff-crefted Wood-pecker. Black; body beneath, line on each fide the neck, nape and rump white; the hind part of the creft brownifh-yellow. It is found in Surinam.

HIRUNDINACEUS; Leffer black Wood-pecker. Black; cap fcarlet; fhoulders dotted with white. It inhabits North America, and is about five inches and a half long. Two varieties of this fpecies inhabit Cayenne. 1. Middle of the breaft red; belly varied with black and grey. 2. Crown with a red fpot; area of the eyes is white; the hind-head is golden. Of this laft variety the whole head of the female is black; the eye-lids are white.

PASSERINUS; Pafferine Wood-pecker. Yellowifh-olive, beneath barred with brown and whitifh; is about fix inches long, and is found in St. Domingo.

STRIATUS; Rayed Wood-pecker. Black ftreaked with olive, beneath olive; front, cheeks, chin, throat, and breaft grey; crown, hind-head, rump, and upper tail-coverts red. There is a variety that has a black crown; it is nine inches long, and is found in St. Domingo.

MELANOCHLOROS; Gold-crefted Wood-pecker. Variegated with black and yellow; the creft is gold; tail is black. It inhabits Cayenne, and is about thirteen inches long. There is a variety that has a black crown; a red creft; the middle tail-feathers are black, the lateral ones are barred with tawny and black.

FLAVESCENS; Yellow-crefted Wood-pecker. Black barred with yellow; pendent creft, chin, cheeks, and neck yellow. It is found in Brazil, and is about the fize of a jay.

CAYANENSIS. This, as its name imports, is found in Cayenne, and is not quite eight inches long. It is olive-coloured; the feathers towards the tip are marked with a black fpot; the crown, chin, and tail are black; the hind-head is red; the cheeks are whitifh; the belly is yellowifh.

FLAVICANS; Yellow Wood-pecker. Yellowifh, crefted; quill-feathers brown; tail black. It inhabits Cayenne, as do the next two. The male bird has a maxillary band.

CINNAMOMEUS; Ferruginous Wood-pecker. Cinnamon colour, with a few yellowifh fpots; the creft and lower part of the back yellow; the tail is black.

MULTICOLOR; Black-breafted Wood-pecker. This fpecies is crefted; rufous; beneath pale rufty; head, chin, and neck orange; nape, throat, breaft, and fpots on the wings black.

ERYTHROCEPHALUS; Red-headed Wood-pecker. Head wholly red; wings and tail black; the belly is white. It is found in North America, and is nine inches and a half long; it migrates and feeds on acorns, fruit, and Indian corn. From the vifits of this bird, the natives are enabled in a meafure to foretell the rigour or clemency of the approaching winter. This fpecies is extremely deftructive to maize fields and orchards. During winter they are very tame, and fometimes come into houfes, as the robin does with us. They are found chiefly in old trees, and the noife which they make with their bills, may, when the air is calm and ftill, be heard at the diftance of a mile and more.

RUBER; the Red-breafted Wood-pecker. Head, neck, and breaft red; back and wings black; belly ochre. It is found at Cayenne.

OBSCURUS; White-rumped Wood-pecker. Dufky, ftreaked and waved with whitifh; beneath it is white; firft quill-feathers black, fecondary white, with two black bars. It inhabits Long ifland, and is nine inches long.

FASCIATUS; Striped-bellied Wood-pecker. The colour of this fpecies is black; the crown, lores, and fub-maxillary band are fcarlet; the belly is ftreaked white and black; tail-feathers white at the tip.

AURANTIUS; Orange Wood-pecker. Above orange; nape, rump, and tail black; is about ten inches long, and is found at the Cape of Good Hope.

SENEGALENSIS; Gold-backed Wood-pecker. Front and cheeks are brown; cap red; back and quill-feathers reddifh-gold; body beneath grey, undulate with brown and white. It is found in Senegal, and is fcarcely larger than a fparrow.

CAPENSIS; Cape Wood-pecker. This, as its name fignifies, is found in the Cape of Good Hope, and is lefs than our lark; it is grey; the back, neck, and breaft are olive; the quill-feathers are dufky; rump and upper tail-coverts red; tail-feathers black. There is a variety that has its back and wings olive-brown; cap, rump, and belly red.

AURATUS; Gold-winged Wood-pecker. Striated tranfverfely with black and grey; the chin and breaft black; the nape is red, and the rump is white. It is found in North America, and is almoft continually on the ground; it feeds on worms and infects, and when thefe are not to be had, on berries and grafs. When fat it is efteemed excellent food. It migrates to Hudfon's Bay, and it does not climb trees.

CAFER; Gold-winged Wood-pecker. Above brown, beneath claret, dotted with black; wings beneath, and fhafts of the wings and tail, vermilion. It is found at the Cape of Good Hope.

OLIVACEUS; Crimfon-breafted Wood-pecker. This fpecies is olive; neck beneath, breaft and rump pale red; chin, throat, quill-feathers and vent dufky brown; the tail above is black.

CAROLINUS; Carolina Wood-pecker. Cap and nape red; back with black bands; middle tail-feathers white, dotted

dotted with black, the reft black. There are three varieties of this fpecies. 1. Front and cheeks pale brown; belly pale yellowifh-brown. 2. Spots on the chin and under the eyes red. 3. Black and white; cap, nape, and belly red; front and neck beneath yellow-grey; fides of the neck from the mouth with a black line.

Undatus; Red-cheeked Wood-pecker. Teftaceous waved with black; temples blood-red. It inhabits Guiana and Surinam, as do the two following.

Rufus; Rufous Wood-pecker. Rufous waved with black; wings, tail, and body beneath deeper. A variety has a black breaft; and under the eyes a black fpot.

Chlorocephalus; Yellow-headed Wood-pecker. Olive, beneath fpotted with white; neck and fubcrefted head yellow; crown red. This is fix inches long.

Miniatus; Red-winged Wood-pecker. Crefted, red, beneath white; throat rofy; bill and tail blue; tail-coverts green. This is nine inches long, and is found in Java.

Malaccensis; Malacca Wood-pecker. Crefted head and fhoulders fcarlet; chin and throat rufous yellow; body beneath barred with black and white; the tail is black. It is found in Malacca, as its name imports.

Pitiu. Brown dotted with white; the tail is fhort. It inhabits Chili; has the appearance of a pigeon, and builds, not in the hollows of trees, but on the banks of rivers and declivities of mountains; it lays ufually four eggs.

* Viridis; Green Wood-pecker. Green; crown crimfon. This is the largeft fpecies found in England, and is full thirteen inches long. Thefe birds are frequently feen on the ground, particularly where ant-hills abound, the population of which they extirpate by their inceffant efforts. This bird will occafionally not be contented with darting its tongue at them fingly, but by the combined exertion of its bill and feet lays open the whole neft, and commits the moft wholefale ravage upon the ants and their eggs. There is a variety found in Mexico, full thirteen inches long; of which the upper part of the head and fpots beneath the ears are deep red; the rump is of a pale yellow. It makes a circular hole in the dead part of trees for its neft, and lays five or fix greenifh coloured eggs fpotted with black; it is remarkably fond of bees.

Bengalensis; Bengal Wood-pecker. Green; creft red; nape black; front and throat variegated white and black; body beneath white. It is eight inches and a half long, and is found in Bengal. A variety of this fpecies is a little larger, and inhabits Ceylon and China. Its head is marked with numerous white fpots; the back is black, and fcarlet in the middle.

Quadrimaculatus; Blue-throated Wood-pecker. Green; beneath blueifh; crown and rump yellow; throat, quill and tail-feathers black. This is the fize of the Viridis, and is found in Ceylon.

Philippinarum; Philippine Wood-pecker. The fize of the laft, and found in Manila. It is brown-green; crefted; beneath fpotted with white and black; the rump is red; the tail-feathers have two white fpots.

Goensis; Goa Wood-pecker. Green, beneath whitifh; crown and crefted hind-head red; tail and fillet reaching from the eyes to the wings black; the wings are golden. It is found in Goa, and is very fimilar to the Bengalenfis.

Manillensis; Manila green Wood-pecker. Dirty-green; crown covered with grey; wings and tail blackifh; upper tail-coverts red. It is found in Manila.

Gartan; Crimfon-rumped Wood-pecker. Above grey-brown, beneath yellowifh-grey; wings with dirty fpots; crown and rump red. It is found in Senegal, and is a good deal lefs than the Viridis.

Canus; Grey-headed green Wood-pecker. Cinereous, front obfcurely fpotted with red; back, fhoulders, wing and tail-coverts green; rump yellow; wings and tail brown; chin whitifh. It inhabits Norway, Ruffia, and Siberia.

Persicus; Perfian Wood-pecker. Pale yellow; body above, tips of the quill-feathers, and area of the eyes, ferruginous. It is a native of Perfia.

Semirostris; Half-billed Wood-pecker. Brown-afh, beneath white; head brown, fpotted with yellowifh; upper mandible fhorter. It is only of the fize of a martin.

Pubescens; Downy Wood-pecker. Back longitudinally downy; outer tail-feathers white, with four black fpots. The male bird has the hind-head red. It is found in Carolina, Virginia, and other parts of North America, and is a very daring bird, and particularly mifchievous to fruit-trees in orchards. As foon as it has pecked one hole in a tree, it makes another clofe to the firft, in a horizontal direction, proceeding till it has made a circle of holes quite round the trunk, fo that the tree frequently dries up and decays.

Villosus; Hairy Wood-pecker. Back fomewhat downy, in a longitudinal direction; the outer tail-feathers are entirely white. It is from nine to twelve inches long. Like the Pubefcens, it is a fad peft to orchards. It inhabits North America, from Hudfon's Bay to Carolina, and it has been feen in the north of England.

* Major; Greater fpotted Wood-pecker. Variegated with black and white; the vent and hind-head are red. This is alfo called the witwall, is nine inches long, and ftrikes with far greater comparative force againft the trees than any of the tribe. It creeps with facility over the branches in every direction; and when any perfon attempts to obferve it on one fide of a branch, it paffes to the oppofite with extreme celerity, repeating this change in correfpondence with every renewed effort of the enemy. It inhabits many parts of Europe, as well as England; here indeed it is lefs frequent than the Viridis, to which it is clofely allied in manners and habits, except that it rarely defcends to the ground in fearch of food. It lays four or five gloffy eggs in the decayed wood, without any formal preparation of a neft.

* Medius; Middle fpotted Wood-pecker. Variegated with white and black, the vent and cap are red. It is doubted if this be a diftinct fpecies, or whether it be not the young of the Major juft defcribed.

* Minor; Leffer fpotted Wood-pecker. This fpecies is alfo variegated with white and black; the crown is red, and the vent teftaceous. It is found in divers parts of Europe and Afia. It has the habits of the Major, but is much more rarely feen. There are two varieties; 1. Crown, nape and fcrag black-grey; body beneath yellowifh, fpotted with black. This is a native of Panay. 2. Hind-head fubcrefted; crown with a crimfon fpot; front, cheeks, and body beneath white. It is found in Ceylon.

Tricolor; Varied Wood-pecker. Black, with white tranfverfe ftreaks; breaft and belly red. It inhabits New Spain.

Canadensis; Canada fpotted Wood-pecker. White; crown, back, fhoulders, and the two middle tail-feathers black, the other tail-feathers and wings varied with black and white. It is a native of Canada, and nine inches long.

Varius; Yellow-bellied Wood-pecker. Variegated black and white; crown red; vent white, barred with brown. It inhabits North America; nine inches long; it is a very numerous tribe, and extremely deftructive to corn and fruits.

Flavipes; Yellow-legged Wood-pecker. Black, beneath white; legs yellow.

Bicolor; the Encenada Wood-pecker. Varied with grey

Strahan and Prefton,
New-Street Square, London.

grey and white; fides of the crefted head white; quill-feathers brown, fpotted with white. The female bird is totally brown, with a creft.

Cardinalis; Cardinalis Wood-pecker. Black, beneath white, fpotted with black; the crown and hind-head red. Found in Luzonia; and is the fize of the Viridis.

Nubicus; Nubian Wood-pecker. Variegated with white, rufous, and brown; crown black, fpotted with white; hind-head fubcrefted; red breaft, whitifh, with black dots; tail with rufous brown lines. It is found in Nubia, and is feven inches and a half long.

Moluccensis; Brown Wood-pecker. Black, waved with white; beneath whitifh, arrow-ftreaked with brown; quill and tail-feathers brown, fpotted with white. It inhabits the Molucca iflands. There is a variety black-brown, fpotted with white; beneath and head white; crown and fpot beneath the eyes brown. It inhabits India, and is five inches long.

Minutus; Minute Wood-pecker. This, the leaft of all the tribe, is found in Cayenne. It is chefnut-grey; beneath whitifh waved with brown; crown red; hind-head black, fpotted with white.

Tridactylus; Three-toed Wood-pecker. Variegated black and white; three-toed; a variety is alfo variegated black and white; and white beneath. The *firft* inhabits America, Europe, and Sicily: the *fecond* is found in Cayenne.

Picus *Cinereus*. See Sitta *Europæa*, S. *jamaicenfis*, and S. *major*.

Picus *Imbrifactus*, or *Picus Principalis* of Linnæus, the name of an American bird, defcribed by Nieremberg, and called by the natives *quatotomimi*. It is of the fize of the hoopoe, and is variegated with black and brown; it is of the wood-pecker kind, having a beak three fingers breadth long, with which it perforates trees: its head is fmall and red, and has a fine red creft; but the feathers are black on their upper fide; it has on each fide of the neck a broad white line, reaching to the breaft; its legs and feet are of a blueifh colour; it builds in high trees, and is principally found near the fhores of the South fea. It feeds on infects. See Picus.

Picus *Major Leucophæus*. See Cuculus *Vetula*.

Picus *Murarius*, the name of a bird called in Englifh the *wall-creeper*, and improperly ranked among the *pici*, as wanting many of the characters of that genus: and therefore claffed in the Linnæan fyftem under the genus of *certhia*, or creeper. It is about the bignefs of the common fparrow; its bill is black, flender, and long; its head, neck, and back grey; its breaft white, and its wings partly grey and partly red; its tail is fhort and black; its long wing-feathers alfo, and the lower part of its belly, and its legs, are of the fame colour; its legs are fhort, but its feet are not placed as in the wood-pecker; but are three before and one behind; it is very common in Italy, Germany, and fome parts of France; it is a very lively and chearful bird, and as the common wood-pecker climbs trees and feeds on the infects in their cracks, fo this bird runs up old walls, and feeds on what it finds in the cracks of the ftones.

Picus *Nidum Sufpendens*, a name by which fome authors have called the galbula; a yellow bird of the thrufh kind, very remarkable for its beauty, and for the ftructure and manner of hanging its neft. See Oriolus *Galbula*.

Picus *Salutiferus*, the name under which Nieremberg has defcribed a Mexican bird, called by the natives *huquecholtototl*.

It is of the fize of the common black-bird, and has a long and black beak: its head and a great part of its neck are red; its breaft and belly are grey, and it has a creft of red feathers upon its head. It is of the wood-pecker kind, and has its name from the fuppofed virtue of its feathers, particularly thofe of the creft, in curing the head-ach.

PIDAURA, in *Geography*, a town of the Morea, anciently called "Epidaurus," fituated on the W. coaft of the gulf of Engia; 35 miles E. of Napoli di Romania. N. lat. 37° 40′. E. long. 23° 24′.

PIDISJARVI, a town of Sweden, in the government of Ulea; 48 miles E. of Gamla Karleby.

PIE, in *Agriculture*, a provincial term applied to fignify a receptacle for preferving potatoes, turnips, and other roots. And when thefe are for potatoes they are ufually formed with dry earth in a dry fituation, being made in the ridge or conical form.

Pies are likewife made ufe of for curing rape-feed, being built in the field with platted ftraw. The form, according to Mr. Marfhall, is that of a corn bufhel, the diameter feven or eight feet, the height three or four feet. This large ftraw bafket-like receptacle is filled with rough feed to the brim, topped up in a conical form with ftraw, and the whole fecured with a coat of thatch. This is moftly done when the markets are bad at the period of thrafhing, as the feed may be preferved any length of time in thefe pies, if there is a fufficiency of pulls among it, and the quantity of feed depofited in them be not too large. It is at prefent a practice feldom employed.

PIECE, in *Commerce*, fignifies fometimes a whole, and fometimes only a part of the whole.

In the firft fenfe we fay, a piece of cloth, of velvet, &c. meaning a certain quantity of yards, regulated by cuftom, being yet entire, and not cut.

In the other fignification we fay, a piece of tapeftry; meaning a diftinct member wrought apart, which, with feveral others, make one hanging.

A piece of wine, of cyder, &c. is a cafk full of thofe liquors.

Piece, *Chimney*. See Chimney.

Piece, *Detached*. See Detached.

Piece, *Eafel*. See Easel.

Piece-*Goods*, in *Commerce*, a name given in India to the various fabrics of manufactured cotton.

Piece, *Mafter*. See Master.

Piece, in *Coinage* and *Commerce*, fignifies fometimes the fame thing with *fpecies*: as when we fay this piece is too light, &c.

Sometimes, by adding the value of the pieces, it is ufed to exprefs fuch as have no other particular name: as a piece of eight rials, a piece of twenty-five fols, &c.

In England, the piece, abfolutely, is fometimes ufed for twenty fhillings fterling, and fometimes for a guinea.

By 6 Geo. II. cap. 25. broad-pieces, of five-and-twenty, or three-and-twenty fhillings value, or any halves or quarters thereof, are called in. And all perfons are forbid to receive or utter them in payment by tale.

Piece *of Eight* denotes the Spanifh dollar or pefo, which in foreign exchanges is valued at 8 reals of old plate or 15 reals 2 maravedis vellon: but in commercial tranfactions within the country, it is reckoned at 15 reals vellon.

As a filver coin, the dollar, or pefo duro, fince the coinage of 1772, paffes for 20 reals vellon, and the half dollar, or efcudo vellon, for 10. This dollar contains 374⅞ troy grains of fine filver, or 405⅓ grains of Englifh ftandard filver; and therefore its value in Englifh filver coin is 4*s*. 4½*d*.; and the half dollar in proportion. The value of the pefo of plate, or dollar of exchange, in Englifh filver coin, is 39½*d*.; but if allowance be made for remedy in coinage, it muft be valued in the dollar at ½ fterling. By the affay aſſay at the London mint, the weight of the dollar is 17 dwt. 8 gr., and its fineneſs 8 dwt. worſe than Engliſh ſtandard: hence its value in Engliſh ſilver coin is 4*s.* $3\frac{3}{4}$*d.*

The average weight of 1000 dollars at the Bank of England is found to be 866 ounces troy.

The Spaniſh dollars coined ſince 1772 have the following impreſſions: head of the reigning king, with his name and DEI GRATIA; reverſe, arms of Spain; which, on pieces coined at Mexico, ſtand between two pillars with NE PLUS ULTRA: legend round the piece, HISPAN. ET IND. REX, with an M. for Mexico; 8 R. for eight reals, and the initials of the moneyer's name: theſe are commonly called Pillar dollars; but thoſe coined in Europe have no pillars; and the legend is only, HISPANIARUM REX. The initials are not at the end of the legend, but by the ſide of the eſcutcheon in place of the pillars. The diviſions of the dollar bear the ſame impreſſions; but the half dollar is marked 4 R.

In the Daniſh iſlands, St. Thomas, St. John, and Santa Cruz, accounts are kept in piaſtres or rix-dollars current (alſo called pieces of eight), each rix-dollar being divided into eight ſchillings or bits, and each bit into ſix ſtivers. Accounts are alſo kept in dollars of 100 cents, as in America. The Spaniſh dollar paſſes here for $12\frac{1}{2}$ bits, and each bit for $6\frac{3}{4}$ ſtivers. Kelly's Univerſal Cambiſt. See COIN and EXCHANGE.

PIECE is alſo a kind of money of account, or rather a manner of accounting, uſed among the negroes on the coaſt of Angola, in Africa.

The price of ſlaves, and other commodities here negotiated, as alſo the duties paid the petty kings, are eſtimated on both ſides in pieces. Thus thoſe barbarians requiring ten pieces for a ſlave, the Europeans, in like manner, value the money, or merchandize, to be given in exchange, in pieces.

PIECE, in *Heraldry*, denotes an ordinary, or charge.

PIECES, in the *Military Art*, include all ſorts of great guns and mortars.

Theſe are alſo called *pieces of ordnance*, or *artillery*.

PIECES, *Field*. See FIELD-*Pieces*.

PIECES, *Battery*. See *Great* GUNS.

PIECES, *Garriſon*. See GARRISON.

PIECE, *Poiſoning a*. See POISON.

PIECE, *Soldier's*. See FIRELOCK.

PIECE, *Elevation of a*. See ELEVATION.

PIECE, *Quadrating of*. See QUADRATING.

PIECE-*Work*, in *Rural Economy*, that ſort which is done by the great or piece. It is ſometimes called taſk-work. This mode of working is becoming more general and neceſſary daily on account of the increaſing price of labour; but in letting it, it requires that the farmer ſhould be well acquainted with its nature, and the time it will take in performing it, or he will be liable to much impoſition: he ſhould likewiſe be a good judge of the proper manner of performing the work. Some are of opinion that the work is never ſo well done in this way. See WORK.

PIED, *Fr.* See FOOT.

PIED, or *pied de Roi*, is the French foot in the old ſyſtem. See FOOT and MEASURE.

PIEDE, or PIETE', *La*, in *Geography*, a town of Mexico.

PIEDI OREZZA, a town of the iſland of Corſica; 12 miles E.N.E. of Corte.

PIEDICORTE, a town of Corſica; 12 miles E.S.E. of Corte.

PIEDMONT, the moſt extenſive province in the northern part of Italy, about 150 Engliſh miles in length by 100 of medial breadth. It is bounded on the N. by the Valais, on the E. by the duchies of Milan and Montferrat, on the S. by the country of Nice and the territories of the Genoeſe, and on the W. by Savoy. This principality was firſt inhabited by Umbrians, Etrurians and Ligurians, and afterwards by Gauls, upon their eſtabliſhment in Italy, under Brennus, &c. which gave occaſion to its being called "Ciſalpine Gaul," or "Gaul on this ſide of the Alps," with regard to Rome. It became in a ſubſequent period a part of Lombardy, and in the 13th century formed a portion of the gradual acquiſitions of the counts afterwards dukes of Savoy, and latterly kings of Sardinia. It is ſaid to have derived its name from its ſituation "ad pedem montium." With regard to its revenue, when that of Sardinia was eſtimated at 1,085,000*l.*, Piedmont contributed 953,750*l.*, Savoy 87,500*l.*, and Sardinia only 43,750*l.* This province is pleaſant and fruitful, and the air mild and pure: the plains produce in abundance wheat, maize, rice, with ſome olives and wine, and the paſturages feed large herds of cattle. The ſoil is a rich ſandy loam, with ſome tracts of large gravel brought down from the rivers; but the heat is exceſſive in ſummer, and the winter cold very ſevere; and yet the ſilk is eſteemed of the fineſt quality. Around Turin, and through a great part of the province, artificial irrigation, or the watering of meadows, is practiſed with great aſſiduity and ſucceſs. The ſurrounding Alps are rich in minerals, and they ſupply numerous ſtreams which fertilize the plains. In the duchy of Aoſta, the mines of copper, accompanied with antimony, arſenic, and zinc, are numerous: and in the ſuperior regions near Macuguaga, there are mines of gold, found in marcaſite and quartz; in the vale of Seſia are the gold mines of St. Maria and Cavavecchia, alſo containing ſilver. Gold is likewiſe found in the mountains of Challend near the vale of Aoſta; and the torrent Evenſon rolls down pebbles of quartz, veined with that precious metal. Not far to the E. of Mont Blanc, a rich vein of cobalt has been lately diſcovered; and plumbago or black lead has been obſerved near the baths of Binay. This principality contains a great number of cities, towns and villages, ſo that the whole country has been denominated a large city. Its capital is Turin, which is an archiepiſcopal ſee; beſides which there are eight biſhoprics. The principal rivers are the Po, the Tanaro, the Sturia, and the Doria. The chief exports conſiſt of ſilk, which are chiefly manufactured at Lyons, ſome hemp, and large herds of cattle. In the year 1802, the whole country was annexed to the French republic, and divided into ſix departments, under the names of the Po, Doria, Marengo, Sezia, Stura, and Tanaro.

PIEDOUCHE, *French*, formed from the Italian *peduccio*, *foot*, in *Architecture*, a little ſtand, or pedeſtal, either oblong or ſquare enriched with mouldings, ſerving to ſupport a buſt, or other little figure. This is called a bracket pedeſtal.

PIEDRA DE LA HYADA, in *Natural Hiſtory*, the name given by the Spaniards to a ſtone found in many parts of America, particularly in New Spain; and famous among the Indians for curing the colic on being applied to the navel. It is green, and is a ſpecies of jaſper, approaching to the nature of the lapis nephriticus, and is called by many *colicus lapis*, from its virtues.

PIEDRAHILA, in *Geography*, a town of Spain, in the province of Leon; 26 miles W.N.W. of Avila.

PIEDRAS, a river of Terra Firma, which runs into the Caribbean ſea, 40 miles E. of Cape Aguja.

PIEDROIT, in *Architecture*, a pier, or a ſquare kind of pillar, part of which is hid within a wall.

The only thing in which it differs from a pilaſter is, that the latter has a regular baſe and capital, which the other wants. See PILASTER.

Piedroit is alſo uſed for a part of the ſolid wall annexed to a door or window; comprehending the door-poſt, chambranle, tableau, leaf, &c.

PIEGAIO, in *Geography*, a town of Italy; 14 miles S.W. of Perugia.

PIELAWESI, a town of Sweden, in the government of Kuopio, ſeated on a lake; 35 miles N.W. of Kuopio.

PIELIS, a town of Sweden, in the government of Kuopio, on a large lake; 70 miles E.N.E. of Kuopio.

PIEMENTE, a town of Iſtria; 11 miles S. of Capo d'Iſtria.

PIENES, a ſmall iſland of Japan, near the harbour of Sacca.

PIENIN, a town of Poland, in the palatinate of Cracow; 36 miles N. of Cracow.

PIENO, a town of Italy, in the department of the Montagna; 18 miles N. of Lecco.

Pieno, Ital. *Full*, in *Muſic*. Sometimes it implies energy or force. See Ripieno.

PIENZA, in *Geography*, a town of Etruria, and the ſee of a biſhop; 45 miles S. of Florence. N. lat. 43° 3′. E. long. 11° 34′.

PIE-POUDER Court. See Court.

PIER, in *Building*, derived from the French *pierre, a ſtone*, denotes a maſs of ſtone, &c. oppoſed, by way of fortreſs, againſt the force of the ſea, or a great river, for the ſecurity of ſhips that lie at harbour in any haven, ſuch are the pier of Dover, deſcribed by Camden Brit. &c., the pier of Ramſgate, and the haven pier of Great Yarmouth, mentioned 22 Car. II.

Piers are alſo uſed in *Architecture* for a kind of pilaſters, or buttreſſes, raiſed for ſupport, ſtrength, and ſometimes for ornament.

Piers, *Circular*, are called *maſſive columns*, and they are with or without caps, and are frequently ſeen in Saracenic architecture.

Piers *of a Bridge*. See Bridge.

M. Belidor obſerves that, when the height of the piers is about ſix feet, and the arches are circular, it is ſufficient to make their thickneſs the ſixth part of the width of the arch, and two feet more; but when the arches become of a great ſpan, the thickneſs of the piers may be reduced to the ſixth part; but then the depreſſion of the two feet doth not take place at once; that is, in an arch of above forty-eight feet, three inches are taken off for every ſix feet of increaſe of the width of the arch. The thickneſs of the piers ſupporting elliptic arches is greater than in the former proportion: thus, in an arch of ſeventy-five feet wide, the thickneſs of the pier, whoſe height is about ſix feet, ſhould be 13.5 when the arch is circular, and fifteen feet when it is elliptical.

The ſame author makes the abutments one-ſixth part more than the piers of the largeſt arch.

Mr. Muller has calculated the following table, containing the thickneſs of the piers of bridges.

Table containing the Thickneſs of the Piers of Bridges.

	6	9	12	15	18	21	24
20	4.574	4.918	5.165	5.350	5.492	5.610	5.698
25	5.490	5.913	6.216	6.445	6.645	6.801	7.930
30	6.386	6.816	7.225	7.513	7.746	7.939	8.102
35	7.258	7.786	8.200	8.532	8.807	9.037	9.233
40	8.404	8.691	9.148	9.523	9.835	10.101	10.328
45	8.965	9.579	10.077	10.489	10.837	11.136	11.394
50	9.805	10.454	10.987	11.435	11.817	12.146	12.434
55	10.640	11.245	11.882	12.364	13.019	13.149	13.218
60	11.400	12.110	12.718	13.281	13.723	14.109	14.314
65	12.265	13.025	13.648	14.185	14.654	15.082	15.433
70	13.114	13.869	14.517	14.049	15.573	16.011	16.400
75	14.000	14.705	15.336	15.965	16.480	16.940	17.354
80	14.747	15.542	16.234	16.842	17.381	17.864	18.298
85	15.513	16.328	17.041	17.674	18.237	18.742	19.194
90	16.373	17.102	17.929	18.578	19.157	19.679	20.152
95	17.184	17.826	18.772	19.438	20.036	20.577	21.068
100	17.991	18.848	19.610	20.293	20.908	21.466	21.976

Th

The firſt horizontal line expreſſes the height of the piers in feet, from 6 to 24 feet, each increaſing by 3: the firſt vertical column, the width of arches from 20 to 100 feet, for every 5 feet.

The other columns expreſs the thickneſs of piers in feet and decimals, according to the reſpective height at the head of the column, and the width of the arch againſt it in the firſt column.

Rectangular piers are ſeldom uſed but in bridges over ſmall rivers; in all others they project from the bridge by a triangular priſm, which preſents an edge to the ſtream, in order to divide the water more eaſily, to prevent the ice from ſheltering there, as well as veſſels from running foul againſt them. This edge is terminated by the adjacent ſurfaces at right angles to each other at Weſtminſter bridge; but thoſe of the Pont-royal, at Paris, make an acute angle of about 60°. However the French, in their later conſtructions, make this angle to terminate by two cylindric ſurfaces, whoſe baſes are arcs of 60 degrees. Muller's Pract. Fortif. part iv. ſect. 1. p. 257, &c.

Pier *Head*, in *Geography*, a cape on the north-eaſt coaſt of New Holland, and weſt point of Thirſty ſound.

PIERA, a town of Spain, in Catalonia; 16 miles N.W. of Barcelona.

PIERACO, a town of the marquiſate of Ancona; 5 miles N. of Ancona.

PIERAGE, money paid for the uſe of a pier.

PIERBACH, in *Geography*, a town of Auſtria; 8 miles N.N.W. of Grein.

PIERCE's Island, a ſmall iſland in Piſcataqua river.

PIERCEA, in *Botany*, a name of Miller's, moſt unfortunately conſtructed, though well intended, to honour the late duke of Northumberland; ſo that it ought to have been *Percya* or *Percæa*. That great patron of Botany, and diſtinguiſhed cultivator, to whom the ſcience is ſo much indebted, has certainly long merited ſuch a compliment, in preference to a cloud of names, in every reſpect far inferior; but Miller's ſuppoſed genus is not in any reſpect different from Rivina. See that article.

PIERCED, Percé, in *Heraldry*, is when an ordinary is perforated, or ſtruck through; ſhewing, as it were, a hole in it.

This piercing is ſaid to be expreſſed in blazon as to its ſhape: thus if a croſs have a ſquare hole, or perforation in the centre, it is blazoned, *ſquare-pierced*, which is more proper than *quarter-pierced*, as Leigh expreſſes it; and accordingly the French call it *percé en quarré*. When the hole or perforation is round, it muſt be expreſſed *round-pierced;* which Gibbon in Latin calls *perforata;* becauſe all holes made with pierces, or augers, are round. If the hole in the centre be in the ſhape of a lozenge, it is expreſſed *pierced lozenge-ways*.

All piercings muſt be of the colour of the field, becauſe piercing implies the ſhewing of what is under the ordinary, or bearing. And when ſuch figures appear on the centre of a croſs, &c. of another colour, the croſs is not to be ſuppoſed pierced, but that the figure on it is a charge, and muſt be accordingly blazoned.

Pierced *Iſland*, in *Geography*, a ſmall iſland or rock, in the gulf of St. Lawrence, pierced with two natural arches, through which the ſea paſſes; 15 miles S. of Cape Gaſpe.

PIERCING, among *Farriers*. *To pierce a horſe's ſhoe lean*, is to pierce it too near the edge of the iron. *To pierce it ſut*, is to pierce it farther in.

PIERCY, in *Geography*, a town of America, in N. Hampſhire, and county of Coos, containing 211 inhabitants.

Piercy *Iſland*, a ſmall iſland near the eaſt coaſt of New Zealand; eaſt of Cape Brett.

PIERIA, in *Ancient Geography*, a country of Syria, in the Seleucide territory. This country derived its name from mount Pierius or Pieria, which the Macedonians ſo called after mount Pierius in their own country. It was the moſt ſouthern country, and touched on Theſſaly, from which it was ſeparated by mountains.—Alſo, a town of Macedonia. —Alſo, a mountain of Syria, which, according to Strabo, extended from the ſouth to the north, and joined with mount Amanus. This mountain took its name from that of Greece. —Alſo, a town of Greece, in Bœotia, afterwards called Lyncos.

PIERIDES, among the *Ancients*, an epithet given to the Muſes, upon account of their having been born in that part of the country of Macedon which was called *Pieria*.

PIERIUS Mons, in *Ancient Geography*, a mountain of Aſia, in Syria, on the coaſt of the Mediterranean ſea, between the gulf Iſſicus to the north and the mouth of the river Orontes; about lat. 36° 15′.

PIERMONT, in *Geography*, a town of America, in the ſtate of N. Hampſhire, and county of Grafton, containing 877 inhabitants.

PIEROUGAMIS, a tribe of Indians in Canada, who inhabit the weſt bank of the lake of St. John.

PIERRE, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the diſtrict of Louhans; 15 miles N. of Louhans. The place contains 1510, and the canton 12,408 inhabitants, upon a territory of 255 kiliometres, in 18 communes.

Pierre *Buſſiere*, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the diſtrict of Limoges; 9 miles S.S.E. of Limoges. The place contains 813, and the canton 8093 inhabitants, on a territory of 217½ kiliometres, in 10 communes.

Pierre *a l'Oiſſeau*, a ſmall iſland in the Engliſh channel, near the coaſt of France. N. lat. 48° 54′. W. long. 3° 24′.

Pierre *Pertuis*, a paſs in mount Jura, cut out of a rock; 8 miles N.W. of Bienne.

Pierre *d'Albigny, St.*, a town of France, in the department of Mont Blanc, and chief place of a canton, in the diſtrict of Chambery. The place contains 2714, and the canton 6943 inhabitants, on a territory of 70 kiliometres, in 6 communes.

Pierre-*Egliſe, St.*, a town of France, in the department of the Channel, and chief place of a canton, in the diſtrict of Valognes. The place contains 1619, and the canton 13,342 inhabitants, on a territory of 170 kiliometres, in 20 communes.

Pierre *d'Oleron, St.*, a town of France, in the department of the Lower Charente, and chief place of a canton, in the diſtrict of Marennes. The place contains 4249, and the canton 9653 inhabitants, on a territory of 135 kiliometres, in 3 communes.

Pierre-*Lette*, a town of France, in the department of the Drome, and chief place of a canton, in the diſtrict of Montelimart. The place contains 2536, and the canton 12,534 inhabitants, on a territory of 327½ kiliometres, in 14 communes.

Pierre-*le-Moutier, St.*, a town of France, in the department of the Nievre, and chief place of a canton, in the diſtrict of Nevers. The place contains 1969, and the canton 8615 inhabitants, on a territory of 310 kiliometres, in 10 communes.

Pierre *ſur Dives, St.*, a town of France, in the department of the Calvados, and chief place of a canton, in the diſtrict of Liſieux. The place contains 1499, and the canton 9287 inhabitants, on a territory of 145 kiliometres, in 28 communes.

Pierre *d'Automne*, a French name tranſlated from the Chineſe.

Chinefe. It is the name of a medicinal ftone, famous throughout the Eaft for curing all diforders of the lungs. Many people fuppofe it had its name of the *autumn-ftone*, from its being only to be made at that feafon of the year; but it may be made equally at all times, and the origin of the name is to be farther fearched into.

The Chinefe chemifts, like thofe of all other nations, delight in a fort of gibberifh. A part of this is, the referring the feveral parts of the body to the feveral feafons of the year. The lungs are in this fcheme referred to autumn. This appears in their writings; and thus the ftone for difeafes of the lungs came to be called *autumn-ftone*.

It is a tedious preparation of human urine, and made as follows: they put thirty pints of the urine of a ftrong and healthy young man into a large iron pot, and fet it over a gentle fire; and when it begins to boil, they add to it, drop by drop, about a large tea-cup full of rape-oil; it is then left on the fire till the whole is evaporated to a thick fubftance refembling black mud; they then take it out of the pot, and laying it on a flat iron, they dry it fo that it may be powdered very fine.

This powder they moiften with frefh oil, and put the mafs into a double crucible, furrounded with coals, where it ftands till thoroughly dried again. They finally powder this again, and putting it into a china-veffel, covered with filk cloth and a double paper, they pour on boiling water, which makes its way, drop by drop, through thefe coverings, till fo much is got in as is fufficient to reduce it to a pafte. This pafte is well mixed together in the veffel it is kept in, and this is put into a veffel of water, and the whole fet over the fire. The matter thus becomes again dried in balneo Mariæ, and is then finifhed. Obferv. fur les Coût. de l'Afie, p. 258.

PIERRE *de Cayenne*, in *Ornithology*. See PHASIANUS *Pauxi*.

PIERREFITTE, in *Geography*, a town of France, in the department of the Meufe, and chief place of a canton, in the diftrict of Commercy; 7 miles W. of St. Michael. The place contains 660, and the canton 9249 inhabitants, on a territory of $357\frac{1}{2}$ kiliometres, in 27 communes.

PIERREFONTAINE, a town of France, in the department of the Doubs, and chief place of a canton, in the diftrict of Baume. The place contains 1110, and the canton 7889 inhabitants, on a territory of $272\frac{1}{2}$ kiliometres, in 21 communes.

PIERREFORT, a town of France, in the department of the Cantal, and chief place of a canton, in the diftrict of St. Flour. The place contains 1266, and the canton 8905 inhabitants, on a territory of $287\frac{1}{2}$ kiliometres, in 11 communes.

PIERRES SONORES, ftones that have a metalline found, of which mufical inftruments of percuffion are made in China. See CHINESE *Mufic*.

PIERREVILLE, ST., in *Geography*, a town of France, in the department of the Ardèche, and chief place of a canton, in the diftrict of Privas. The place contains 1471, and the canton 7856 inhabitants, on a territory of $147\frac{1}{2}$ kiliometres, in 7 communes.

PIERSZAIE, a town of Lithuania, in the palatinate of Wilna; 60 miles E. of Lida.

PIERUS, or PEIRUS, in *Ancient Geography*, a river of the Peloponnefus, in Achaia Propria, which traverfed the territory of the town Pharæ. Strabo fays that it difcharged itfelf into the Achelous.—Alfo, a lake of Theffaly.—Alfo, a mountain of Macedonia. It is faid that a perfon, named Pierus, eftablifhed on this mountain the worfhip of the Mufes, whence they were denominated "Pierides."

PIES, in our *Ancient Law-Books*. Freres Pies were a fort of monks, fo called becaufe they wore black and white garments, like magpies; the fame, we fuppofe, with thofe fince called Carmelites, who, for a like reafon, were anciently called by the French Freres Barrez.

They are mentioned by Walfingham, p. 124. "In quodam veteri cœmeterio, quod fuerat quondam fratrnm, quos Freres Pies veteres appellabant."

PIESKE, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 40 miles W.S.W. of Novogrodek.

PIESMA, a word ufed by the ancients to exprefs the remaining mafs, after the expreffion of any fluid fubftance from among its moft folid parts. Thus the cake remaining in the bag, after the expreffion of oils, is called by this name; but there are inftances of authors calling the expreffed juice, inftead of the refiduum, by this name. Thus Diofcorides calls the expreffed juice of the bay-berries, the *piefma laurinum;* and others, the expreffed juice of rofes, *piefma rofarum*, paying no regard to the rofe-cake left behind.

PIESTER, the name ufed by the ancients for the prefs which they employed in preparing the feveral juices of plants, &c.: hence the word *piefma;* which fee.

PIESTRON, a word ufed by Hippocrates to exprefs a fort of forceps, which he recommends to be ufed in difficult labours, to break the bones of the cranium of the fœtus, when its head is too large to fuffer it to pafs whole. It was alfo called *embryothlaftes*.

PIETANTIA, or PITTANCE, a portion of victuals diftributed to the members of a college, or other community, upon fome great feftivals.

PIETANTIARIUS. See PITANCIARIUS.

PIETERMAN, in *Ichthyology*, the name ufed by fome for a fifh of the cuculus kind, approaching to the nature of the *draco marinus*, or weaver; and more ufually called among authors by its Brafilian name, *niqui*.

PIETISTS, in *Ecclefiaftical Hiftory*, a religious fect that fprung up towards the clofe of the 17th century, among the Proteftants of Germany; feeming to be a kind of mean between the Quakers of England, and the Quietifts of the Romifh church.

This fect originated in the zeal of certain perfons, who, with the beft intentions, endeavoured to ftem the torrent of vice and corruption, and to reform the licentious manners both of the clergy and of the people. However, many, deluded by the fuggeftions of an irregular imagination, and an ill-informed underftanding, or guided by principles and views of a more criminal nature, fpread abroad new and fingular opinions, falfe vifions, unintelligible maxims, auftere precepts, and imprudent clamours againft the difcipline of the church: all which excited the moft dreadful tumults, and kindled the flames of contention and difcord.

The learned Spener was at the head of the firft reformers, who, by the private focieties he formed at Frankfort, with a defign to promote vital religion, roufed the luke-warm from their indifference, and excited a fpirit of vigour and refolution in thofe who had been fatisfied to lament in filence the progrefs of impiety. With this view he publifhed a book, entitled "Pious Defires," in which he reprefented in an affecting manner the diforders of the church, and propofed the remedies that were proper to heal them. The religious meetings above-mentioned, or colleges of piety as they were called, however well defigned in their original eftablifhment, tended in many places to kindle in the breafts of the multitude the flames of a blind and intemperate zeal, whofe effects were impetuous and violent:

violent: ſo that theſe inſtitutions of pietiſm became objects of reproach and occaſions of complaint.

The tumult this produced was farther promoted by the commotions that aroſe at Leipſic in the year 1689, when certain pious and learned profeſſors of philoſophy undertook to explain the ſcriptures in their colleges, with a view of forming candidates for the miniſtry into a more accurate acquaintance with theſe ſources of religious knowledge. The novelty of this method of inſtruction excited attention, and the lectures that were delivered to this purpoſe were much frequented. Suſpicions and rumours of an unfavourable kind were ſoon induſtriouſly propagated, and the profeſſors were prohibited from purſuing the plan of religious inſtruction which they had undertaken. During theſe troubles and diviſions, the invidious denomination of Pietiſts was firſt invented; or at leaſt before this period it was not commonly known. It was originally applied by ſome inconſiderate perſons to thoſe who frequented the biblical colleges, and lived in a manner ſuitable to the inſtructions and exhortations that were there addreſſed to them; and afterwards it was uſed to characteriſe all who were diſtinguiſhed by the exceſſive auſterity of their manners, or who, regardleſs of truth and opinion, were only intent upon practice, and turned the whole vigour of their efforts towards the attainment of religious feelings and habits. At this time the denomination was alſo ſometimes applied to perſons whoſe motley characters exhibited an enormous mixture of profligacy and enthuſiaſm, and who better deſerved the title of delirious fanatics. The conteſt, thus begun, very ſoon ſpread through all the Lutheran churches in the different ſtates and kingdoms of Europe. Many perſons of various ranks and profeſſions, of both ſexes, learned and illiterate, pretended a divine impulſe for pulling up iniquity by the root, and reſtoring to its primitive luſtre the declining cauſe of piety and virtue, and for eſtabliſhing a better diſcipline in the Chriſtian church. Aſſemblies, ſimilar to thoſe eſtabliſhed by Spener, were introduced for this purpoſe into Leipſic and other places: but they were not all conducted with prudence and order. Into theſe aſſemblies there were introduced ſeveral extravagant and hot-headed fanatics, who foretold the deſtruction of Babel, *i. e.* the Lutheran church; who terrified the populace with fictitious viſions, aſſumed the authority of prophets honoured with a divine commiſſion, revived doctrines that had long before been exploded and condemned, declared the approach of the millennium, and were guilty of many outrages againſt order and peace. The governors of the church and of the ſtate were alarmed at the progreſs of the diviſions which theſe enthuſiaſts produced, and many ſevere laws were enacted againſt the Pietiſts. Theſe revivers of piety were of two kinds: one ſect, at the head of which was Spener, propoſed to carry on their plan without introducing any change into the doctrine, diſcipline, or form of government in the Lutheran church: the other party were for introducing conſiderable alterations both in doctrine and eccleſiaſtical polity. Many miſtakes have been occaſioned by confounding theſe two parties; the former of which were zealouſly intent upon a very important object, the revival of piety, and, with this view, the reformation of public ſeminaries, where miniſters were educated, both as to the mode of inſtruction and the extent of diſcipline: but the latter were, for the moſt part, totally deſtitute of reaſon and judgment; their errors were the reveries of a diſordered brain; and they were rather to be conſidered as lunatics than as heretics. Some among them were leſs extravagant, and tempered the ſingular notions they had derived from reading or meditation, with a certain mixture of the important truths and doctrines of religion. They were moſtly, however, of the myſtic kind. For a more particular account we muſt refer to Moſheim's Eccl. Hiſt. vol. iv. 8vo.

Many groſs errors are charged on the Pietiſts, in a book intitled "Manipulus Obſervationum Antipietiſticarum;" but they have too much the ſeverity of polemical exaggeration; at leaſt it is certainly ſo with regard to a great part of them.

In effect, there are Pietiſts of ſeveral kinds: ſome run into groſs illuſions, and carry their errors to the overturning a great part of the Chriſtian doctrine; others are only viſionaries; and others very honeſt and good people, who, diſguſted with the coldneſs and formality of other churches, and charmed with the fervent piety of the Pietiſts, are attached to their party, without giving in to the groſſeſt of their errors.

PIETISTS, otherwiſe called the "Brethren and Siſters of the Pious and Chriſtian Schools," a ſociety formed in the year 1678, by Nicholas Barre, and obliged, by their engagements, to devote themſelves to the education of poor children of both ſexes.

PIETOSA, in the *Italian Muſic*, ſignifies to play or ſing in a ſoft manner, fit to move pity or compaſſion.

PIETRA CASTELLO, in *Geography*, a town of Naples, in Capitanata; 6 miles N.W. of Volturara.—P. *Corbara*, a town of Corſica; 11 miles N. of Baſtia.—P. *Galla*, a town of Naples, in Baſilicata; 2 miles S.S.W. of Acerenza.—P. *Mala*, a town of Naples, in Calabria Citra; 11 miles S. of Coſenza.—P. *Malera*, a town of Naples, in Lavora; 7 miles N. of Capua.—P. *Maura*, a town of Naples, in Capitanata; 4 miles N.W. of Leſina.—P. *Paula*, a town of Naples, in Calabria Citra; 4 miles W.N.W. of Cariati Vecchia.—P. *Pertoſa*, a town of Naples, in Baſilicata; 12 miles S.E. of Potenza.—P. *Prezia*, a town of Sicily, in the valley of Noto; 10 miles S.W. of Caſtro Giovanni.—P. *Pugno*, a town of Corſica, in the department of Corté.—P. *Pulcina*, a town of Naples, in Principato Ultra; 3 miles N. of Benevento.—P. *Pulema*, a town of Naples, in Principato Ultra; 9 miles N.N.E. of Benevento.—P. *di Roma*, a town of Sicily, in the valley of Demona, on the N. coaſt; 18 miles W. of Pati.—P. *Sama*, a town of the republic of Lucca; 12 miles W. of Lucca.—P. *Santa*, a town of Etruria; 6 miles S.E. of Meſſa.—P. *Vairan*, a town of Naples, in Lavora; 11 miles E. of Sezza.

PIETRA *Mala*, a mountain that riſes in the middle of the Apennines on the road to Bologna, about 40 miles from Florence. This mountain is rendered remarkable by a flame that ſpreads over a ſmall part of its ſurface, and burns almoſt continually without producing any of thoſe deſtructive effects which accompany volcanic exploſions. A ſimilar phenomenon is obſerved on the ſide of a mountain about four miles from Cavigliano: here the flame, which ſhews itſelf low down on the declivity of the mountain, covers a ſpace of about 140 feet; and it runs along in crevices, and burns much ſtronger in ſome places than in others. Its colour is either bright yellow, or blue, like ſpirits of wine, and it riſes little more than half a foot from the ſurface; but in rainy weather, and particularly in winter, it is ſaid to increaſe conſiderably, and mount to the height of ſix or ſeven feet. It was extinguiſhed in ſome places by waving hats ſtrongly over it, and reproduced by firing a piſtol into a ſmall train of gunpowder, and ſometimes by merely throwing a lighted paper upon the ſpot where it had diſappeared. It emits a ſtrong odour, reſembling that of ether. Naturaliſts are divided in their opinions as as to the caufe of this phenomenon: fome fuppofe it to be electric, others phofphoric, and others again volcanic. In favour of this latter opinion, it is alleged that there are veftiges of ancient eruptions in the neighbourhood; that fhocks of earthquakes frequently agitate the furrounding mountains; and that fulphureous bubbles are perceivable in the vicinity, which are fo inflammable as to take fire at the approach of a torch, &c. But on the other hand, it is faid, that if the flames of Pietra Mala proceeded from any fuch caufe, the ground over which they hover muft be heated, and its heat increafe if opened, becaufe it would be nearer the fubterranean furnace. On the contrary, the flame in this mountain communicates but little heat when burning, and when extinguifhed leaves the ground cold, and without the ufual veftiges of fire. Hence others have been led to afcribe it to a fort of oily fubftance or petroleum, with which they fuppofe the adjacent earth to be impregnated. But if this were the caufe, it is faid, that the flames, inftead of being increafed, would be diminifhed or extinguifhed by the rains and tempefts of winter, and the crevices which emit the flame muft exhibit fome traces of this oily vapour; but the flame glows with the greateft vivacity in winter, and the foil manifefts no appearance of any oily or bituminous fubftance. The firft of thefe facts is equally decifive againft the operation of the electric fluid and phofphoric exhalations. Whatever be its caufe, the flame illuminates the whole tract around it, and banifhes the horror of night from one of the moft dreary folitudes of the Apennines. Similar phenomena were obferved in or near the fame region anciently, as Pliny the elder (lib. xi. cap. 3.) notices the appearances of flames in the territory of Mutina, which includes the neighbouring Apennines.

PIETRA *Embofcata*, in *Natural Hiftory*, a name given by the Italians to the Florentine marble, fo remarkable for its delineations.

This marble is found in thin ftrata, and is full of cracks: in thefe cracks there is ufually found a black mineral matter, which, getting into the fubftance of the ftone a little way on each fide of the crack, forms there various delineations, or the figures of pieces of mofs, bufhes, and the like: the paler pieces of the marble ufually have thefe delineations; the darker coloured having the forms of trees and houfes, or the ruins of old buildings.

PIETRAFEZA, in *Geography*, a town of Naples, in Bafilicata; 7 miles S.W. of Potenza.

PIETRAGRUA, CARLO LUIGI, of Florence, in *Biography*, a mafter of confiderable reputation in his day, compofed two operas for Venice; "Il Paftor Fido," in 1721; and "Romolo e Tazio," in 1722. Profeffors fpeak of Pietragrua in fuch terms as remove all doubt of his merit.

PIETRALBO, or PETRALBO, in *Geography*, a town of the ifland of Corfica; 10 miles S. of St. Fiorenzo.

PIETY, *Mounts of*. See MOUNT.

PIEVE, in *Geography*, a town of Genoa; 2 miles N.W. of Albenga.

PIEVE, *La*, a town of Italy, in the department of the Lower Po, on the Reno, furrounded with an earthen rampart and a ditch.

PIEVE *del Duca*, a town of Italy, in the department of the Rubicon; 4 miles W. of Rimini.

PIEVE *del Mona*, a town of Italy, in the department of the Upper Po; 5 miles E.N.E. of Cremona.

PIEVE *St. Giacomo*, a town of Italy, in the department of the Upper Po; 7 miles E. of Cremona.

PIEVE *a Sieve*, a town of Etruria; 10 miles E. of Florence.

PIEVE *di Cadora*. See CADORA.

PIEVE *di Sacco*, a town of Italy, in the Paduan, on a canal called Fiumcello, containing 5100 inhabitants; 10 miles E. of Padua.

PIEVE *de St. Mauritio*, a town of Italy, in the department of the Upper Po; 12 miles E. of Cremona.

PIEVE *St. Stefano*, a town of Etruria, on the Tiber; 15 miles N. of Arezzo.

PIEUX, LES, a town of France, in the department of the Channel, and chief place of a canton, in the diftrict of Valognes; 12 miles W. of Valognes. The place contains 1398, and the canton 10,420 inhabitants, on a territory of 170 kiliometres, in 15 communes.

PIEXE-GALLO, in *Ichthyology*, a name given by the Portuguefe to a fifh caught about the fhores of the Brafils, and much refembling our *doree* or *faber pifcis;* more ufually known among authors by its Brafilian name, *abacatuaia*.

PIEXE-*Porco*, a name by which fome authors have called the *monoceros*, or unicorn-fifh of Clufius. The name is Portuguefe, and fignifies hog-fifh, this little creature having a mouth like a hog.

PIEXMAHL, in *Geography*, a town of Sweden, in the government of Kuopio; 39 miles S.S.W. of Kuopio.

PIFENDEL, in *Biography*, an eminent performer on the violin, in the fervice of Auguftus II., king of Poland. According to Quantz, Pifendel had in his youth received inftructions in finging from Piftocchi, and on the violin from Tofelli. Quantz is very warm in his praifes, calling him a profound theorift, a great performer, and a truly honeft man. It was from this worthy concert-mafter, fays he, that I learnt to play an adagio, and to compofe in many parts.

Pifendel had in his youth travelled through France and Italy, where he had acquired the peculiarities in the tafte of both countries, and fo blended them together as to form a third genus, a mixed ftyle of writing and playing, which was half French and half Italian. Influenced by his example, Quantz declares that he always preferred this compound ftyle to that of Italy, France, or the national ftyle of his own country.

PIFFERO, Ital. a flute, fife, or flageolet.

PIG, a fmall animal of the hog or fwine kind. See HOG, and SWINE.

PIG, *Guinea*. See CAVIA *Cobaya*.

PIG-*Nut*, or *Earth-nut*, in *Botany*. See BUNIUM.

PIG-*Nut*. See WALNUT-*Tree*.

PIG-*Cafe*, in *Agriculture*, a fort of narrow cafe or ftall, in which an animal of this kind is confined while it is undergoing the procefs of fattening, fo as not to be able to turn itfelf completely round, by which it is fuppofed to fatten better and more expeditioufly, as well as with a lefs quantity of food in proportion to that which is ufed for equal fized animals fed in other methods.

Thefe cafes are conftructed in feparate divifions, in fuch a manner, that each of them may contain a pig, and fit him as nearly as poffible when he is in it; but he muft not be able to turn himfelf round; there is, however, a fpace left at the bottom of each of them, by which he is enabled to lie down at pleafure, in which cafe his feet pafs through the fpace left. Upon one fide of fuch buildings there is ufually a range of fmall troughs in the walls or boardings, and on the other a row of fliders, which fhut the pigs in. The paving in the bottoms of thefe divifions flopes gently backwards to prevent wetnefs, and no litter is ever employed in them, but they are kept clean and fweet by the ufe of a hoe and broom.

Pig-cafes of this fort are fometimes raifed from foundations laid in the ground, and at others erected upon wheels in in a kind of wooden building, fo as to move about on grafs-land. They are frequently met with in the neighbourhood of Maldon in Effex, and will be more fully noticed in fpeaking of fwine. See SWINE.

PIG-*Stie*, in *Rural Economy*, the name of the place where hogs are kept. Buildings of this kind fhould always be large and commodious. See HOG-*Stie*.

PIG-*Tail*, in *Agriculture*, a provincial term fometimes applied to a fmall ftrip of ground generally in the ftate of grafs.

PIG *of Lead*, the eighth part of a fother; amounting to about 250lb. weight.

PIG *Creek*, in *Geography*, a river of Virginia, which runs into the Staunton, N. lat. 36° 52′. W. long. 79° 42′.

PIG *Iron*, in the *Iron Works*. Thofe maffes of iron which refult from the firft procefs of extracting from the ore, are called *pigs*, and in this ftate it is called *pig iron*. It is principally ufed to diftinguifh it from bar iron, which is malleable, and nearly pure iron. Pig iron is of various qualities, according to the quantity of carbon it contains. The higheft carburet is called N° 1, the next N° 2, and fo on. That containing the loweft dofe of carbon, which is known by its white fracture, and greater hardnefs, is called *forge pig*, becaufe it has been thought the moft fitted for making malleable iron. See the article IRON.

PIGALLE, JOHN BAPTIST, in *Biography*, an eminent French fculptor, was born at Paris in 1714. He was the fon of a carpenter employed about the royal buildings, and fhewed an early fondnefs for modelling, which at length gave him a defire for excelling in the art of fculpture. He fpent three years at Rome in copying after the antique, and on his return ftopt at Lyons, where he met with employment which occupied him a year and a half. Here he finifhed his model of the ftatue of Mercury, which he brought with him to Paris, where it was greatly admired. It was fome time before he met with encouragement; but at length he excited the attention of the minifter, and of Mad. Pompadour, who obtained for him many commiffions. He was admitted into the academy of painting and fculpture in 1744, and having executed his Mercury in marble, he made a Venus for its companion, which was equally the fubject of praife. Both thefe ftatues were prefented by the king to Frederic of Pruffia. Pigalle was employed, in 1756, to execute a maufoleum for marfhal Saxe, which was faid to be the grandeft compofition in fculpture that exifts. This caufed him to be employed for the monument erected in 1765, by the city of Rheims, to the glory of Lewis XV. In 1780 he was employed on a grand monument for the count d'Harcourt. His concluding piece was the figure of a young girl taking a thorn out of her foot, which was greatly admired for its beauty and delicacy. He died in 1785, being then rector and chancellor of the academy. As an artift he was entirely indebted to ftudy and application: his fkill was rather talent than genius, and his ideas were rather juft than extenfive.

PIGAYA, in *Natural Hiftory*. See PYGAYA.

PIGEON, in *Ornithology*. See COLUMBA.

PIGEON, in *Rural Economy*, a well-known domeftic bird. There are only two diftinct forts of pigeons, the wild and the tame; and the tame rough-footed ones differ not much from the wild, only they are fomewhat bigger, and more familiar: the wild ufually perch upon trees, being more feldom feen on the ground. They are fuch as breed in woods, fea-rocks, &c. and the tame fuch as are bred in dove-houfes.

But the varieties in the tame fort are numerous, and diftinguifhed by a variety of different names, as carriers, croppers, powters, horfemen, runts, jacobins, turbits, helmets, nuns, tumblers, barbs, petits, owls, fpots, trumpeters, fhakers, turners, finikins, &c. from which, when differently paired, are bred baftard pigeons, fuch as are called from the cropper or powter, and the carrier, powting horfemen; from the tumbler and the horfemen, dragoons. Thefe, however, deferve little attention, being only kept for fancy, and not profit, though the fame method is ufed in breeding them.

And there are different forts of runts, one called Spanifh runt; generally of a blood-red or mottled colour: they are very loofe feathered, and large bodied, but breed not fo often as the fmaller forts.

The horfemen are excellent breeders, and are not eafily took; the common Englifh runt is alfo a good fized pigeon, and breeds well.

Alfo the pigeon called the Leghorn is a fort of runt, only diftinguifhed by a little wattle over his noftril: he is a full bodied pigeon, whofe feathers lie clofe to the body, and is an excellent breeder, and generally of a grizzled colour, ermined round the neck.

It may be noticed that thofe who keep pigeons for the purpofe of breeding, fhould have baftard bred pigeons, fuch as powting horfemen, powting dragoons, from a powter or cropper, and a Leghorn; as fuch pigeons will breed nine or ten pair of young ones in the year; and when they have young ones they feed them well.

But of thofe kinds which are bred in pigeon-houfes, the grey pigeon, inclining to afh colour and black, is the beft; and generally fhews fruitfulnefs by the rednefs of the eyes and feet, and by the ring of gold colour which is about the neck.

In refpect to the time of ftocking there are two feafons in the year at which the pigeon-houfe may be fupplied: the firft is May; for the pigeons having much ftrengthened themfelves during the winter, are in a condition foon to yield profit to the buyer. Secondly, in Auguft, when there are a great number of young pigeons that have been well fed with corn, from the harveft in that feafon. In general pigeons will live about eight years, but they are only prolific for the firft four years; afterwards they are worth nothing, for when they are once paft that age all they do is, to prevent the profit that might be reaped by others that are younger. It is fomething difficult to know how to diftinguifh their age, and requires experience.

And the runts may be diftinguifhed again into greater or fmaller: thofe which are called the Spanifh runts are much efteemed, being the largeft fort of pigeon, but are fluggifh and more flow of flight than the fmaller forts of runts: but the fmaller runts are better breeders, and quicker of flight, for which they are efteemed. As for the colours of their feathers, they are uncertain, fo that a judgment cannot be made of the fort by them.

The next fort which makes the largeft figure, but is not, in reality, the largeft bird, is the cropper, fo called, becaufe they ufually, by attracting the air, blow up their crops to an extraordinary bignefs, even fo as to be fometimes as large as their bodies. This fort is the moft valued, according as it can fwell up its crop. The bodies of this fort are about the bignefs of the fmaller runts, but are fomewhat more flender: this fort alfo is of various colours in the feathers.

The fhakers are of two forts, *viz.* the broad-tailed fhaker, and the narrow-tailed fhaker: thefe are fo called, becaufe they are almoft conftantly wagging their heads and necks up and down; the broad are diftinguifhed from the narrow, in that the broad-tailed fort abounds with tail-feathers about twenty-fix in number; but the narrow-tail ſhakers have not ſo many. Theſe, when they walk, carry their tail-feathers and creſt ſpread abroad like a turkey-cock: they have likewiſe a diverſity of feathers.

The jacobins, or cappers, are ſo called on account of certain feathers which turn up about the back part of the head: ſome of this ſort are rough-footed; they are ſhort billed, the iris of their eye of a pearl colour, and the head is commonly white.

The turbit, which ſome ſuppoſe to be a corruption of the word corbeck, or curtbeke, as they are called by the Dutch, which ſeems to be derived from the French, court-beck, and ſignifies a ſhort bill, for which this pigeon is remarkable; has the head flat, and the feathers on the breaſt ſpread both ways; theſe are much of the ſame ſize with the jacobines.

The carriers are thoſe pigeons which are ſaid to have been employed ſometimes in carrying letters, &c. They are about the ſize of common pigeons, and of a dark blue or blackiſh colour, which is one way of diſtinguiſhing them from other ſorts: they are alſo remarkable for having their eyes compaſſed about with a broad circle of naked ſpongy ſkin, and for having the upper chap of their beak covered more than half from the head, with a double cruſt of the like naked fungous body. The bill, or beak, is moderately long, and black.

The barb, or Barbary pigeon, is another ſort, whoſe bill is like that of the turbit, ſhort, and thick, having a broad and naked circle of a ſpongy white ſubſtance round about the eye, like that of the carrier pigeon; the iris of the eye is white, if the feathers of the pinion are inclinable to a darker colour, but if red they are white, as it is obſerved in other birds.

The ſmiters are ſuppoſed to be the ſame the Dutch call dragors: theſe ſhake their wings as they fly, and riſe commonly in a circular manner in their flight, the males, for the moſt part, riſing higher than the females, and frequently falling and flapping with their wings, which makes a great noiſe that may be heard a great way off, which often is the cauſe of their breaking or ſhattering their quill-feathers. Theſe very much reſemble the tumbler pigeon; the difference chiefly is, that the tumbler is ſomewhat ſmaller, and in its flight will tumble itſelf backward over its head; the diverſity of colours in the feathers makes no difference.

The helmet pigeon is diſtinguiſhed from the others, becauſe it has the head, the quill-feathers, and the tail-feathers, always of one colour, ſometimes black, ſometimes white, or red, or blue, or yellow, but the other feathers of the body are of a different colour.

The light horſeman; this is ſuppoſed to be a croſs between a cock cropper and a hen of the carrier breed: becauſe they ſeem to partake of both, as appears from the excreſcence of fleſh upon their bills and the ſwellings of their crops: theſe are not inclined to leave the place of their birth, or the houſe that they have been uſed to.

The baſtard-bill pigeon is ſomething bigger than the Barbary pigeon; they have ſhort bills, and are generally ſaid to have red eyes, though probably thoſe coloured eyes belong only to thoſe that have white feathers.

There is a pigeon called the turner, which is ſaid to have a tuft of feathers hanging backwards on the head which parts like a horſe's mane.

There is alſo a pigeon of the ſmaller ſort, called the finnikin, but in other reſpects like the former.

There is another pigeon called the ſpot, ſuppoſed to take its name from a ſpot on the forehead, juſt above the bill; and the feather of its tail is always of the ſame colour with the ſpots, and all the other feathers are white.

The Mahomet, or mawmet pigeon, ſuppoſed to be brought from Turkey, is ſingular for its large black eyes, but the other parts are like thoſe of the Barbary pigeon.

It is neceſſary to obſerve that great care muſt be taken to make convenient places to breed in; each pair of pigeons muſt have two neſts, thoſe with baſkets in them are beſt, as before one pair can go out of the neſt, or feed themſelves, the old ones will be ſitting again. When the young ones are taken, clean out the neſt, or put in a clean baſket, for cleanlineſs is a circumſtance of great conſequence to the raiſing of pigeons.

Many ſuppoſe that, notwithſtanding pigeon-houſes are common on many farms, it is, in very few inſtances, that this kind of ſtock, when the various diſadvantages of it are conſidered, can be converted to much profit by the farmer. And it has been well remarked by Mr. Pitt, in his Corrected Report of Staffordſhire, that the increaſe of pigeons beyond a certain degree muſt, doubtleſs, be injurious to the cultivation of grain; within due bounds they do little harm; but increaſed beyond it, they prove pernicious vermin, both to the new ſown crops, and the early part of harveſt. They are particularly voracious in early peas; therefore, the advantages ariſing from their increaſe for conſumption as food are more than counterbalanced by the miſchief occaſioned by their depredations. Mr. Kent alſo ſtates that, in Norfolk, pigeons are much fewer than formerly, as many of the pigeon-houſes have been dropped, on account of the injury which the pigeons do to thatched buildings. And the ſame is the caſe in Kent and other counties. They are particularly injurious to the grain crops firſt at the time of harveſt, by ſettling in large flights upon the ſtanding corn, and in this way doing more miſchief by beating it down than by the quantity they conſume, as Mr. Parkinſon has noticed in his Experienced Farmer. It is ſtated, that where this ſort of ſtock is kept warm ſheltered, ſunny ſituations are the moſt advantageous, as the pigeon delights in warmth, and in being expoſed to the full influence of the ſun. See PIGEON-*Houſe*.

And it is alſo of importance in the economy of theſe birds that the floor of the houſe be nearly upon a level with the holes where they enter, and that theſe holes be not too large nor too numerous; the holes where they form their neſts ſhould not be much encloſed, as pigeons delight in being at liberty. Salts and ſtrong ſcents, ſuch as aſſafœtida, are ſaid to be agreeable to theſe birds, ſo as frequently to attach them to their habitations, when they would not under other circumſtances.

Birds of this kind ſeldom lay more than two eggs at one laying, ſitting about twenty days, the male and female alternately. They are capable of breeding frequently, but in general only produce two or three broods or flights in the year. Of all the ſeveral ſorts the common blue pigeon is probably the moſt productive. The tumblers are ſmall but very domeſtic. The writer of the Experienced Farmer, after recommending the harveſt flight as the moſt proper for the purpoſe of ſtock, as being the ſtrongeſt to withſtand the winter ſeaſon, gives the following directions on the management of them; in regard to feeding them, it is adviſed as only neceſſary during the ſeaſon between ſeed time and harveſt, when it ſhould be done by three or four o'clock in the morning, as they riſe early. If you ſerve them much later, they will keep hovering about home, and be prevented taking their neceſſary exerciſe. If fed the year round, they will not feed near ſo well as if forced to ſeek their own food, for they pick up in the fields what is pleaſant and healthy to them, and from the beginning of the harveſt to the end of ſeed time they find plenty. They may be fed with tares,

grain,

grain, or feeds of any kind. He directs us to be cautious of not letting the firft flight fly to increafe the ftock, but let every one of them be taken; as thefe will come in, in what is called benting time, that is, between feed time and harveft. It is then that pigeons are the fcarceft; and many of the young ones would pine to death through weaknefs during that feafon, and that, at the latter end of every flight, care fhould be taken to deftroy all thofe eggs which were not laid in a proper time. The proper time for the fpring flight is in April and May. After the harveft flight cold weather begins to come on, which injures the old pigeon much if fhe fits late; and the young will be good for nothing if hatched.

And it is very neceffary to pay attention to cleanlinefs in the management of the dove-cote, as already noticed. Before breeding time the holes ought to be carefully examined and cleaned, for if any of the young die in the holes in the fummer time, maggots are foon bred in them; they become putrid, and emit a putrid and unwholefome ftench, very injurious to the inhabitants of the dove-cote. Pigeons are tenacious of their nefts, as appears from the conduct of the wood-pigeon, which will breed for years in the fame tree, and the mother forfakes her neft with regret; but, unable to endure the filth and ftench of her dead offspring, fhe is obliged to quit the eggs fhe has laid for a fecond brood, and the prime of the feafon is loft. Every fummer, immediately after the firft flight, the nefts fhould be all cleaned out, and the dung totally taken away, as it breeds filth. But remember to do this bufinefs early in the morning. The remaining eggs ought likewife to be deftroyed, and a perfectly clean habitation made for the harveft flight of thefe birds. It is directed never to go into a dove-cote later than mid-day, but as early in a morning as convenient. Whatever repairs are neceffary, either to the building or to the nefts, fhould be done before noon; for if you difturb the pigeons in the afternoon, they will not reft contentedly the whole night; and the greateft part perhaps will not enter the cote until the next day, but will fit moping on the ground; and if in breeding time, either a number of eggs may be fpoiled, or feveral young ones ftarved to death. It is added, that pigeons are fuppofed to be more productive from the breeds being croffed; in proof of which, a few tame pigeons were put into a dove-cote; and the confequence was, that a more early, and a more numerous hatch of young were produced than in any of the neighbouring cotes at the fame feafon. It is alfo farther ftated that thefe birds have a great antipathy to owls, which find their way fometimes into dove-cotes; and there is no getting rid of fuch troublefome guefts but by deftroying them. Rats are terrible enemies to pigeons, and will foon deftroy a whole dove-cote. Cats, weafels, and fquirrels will do the fame. It will be neceffary, therefore, to examine the dove-cote once every week at leaft, very minutely, to fee that there are none of thefe intruders in the houfes where they are kept.

In fome cafes, in order to catch and deftroy pigeons, where they become troublefome to the farmer, it has been directed to take a good number of fmall twigs, and birdlime them well, laying them on the ground where pigeons, &c. frequent, and they will foon be entangled with them; and, in order to allure them to the twigs, two or three pigeons may be tied to the ground, among the twigs. And another mode is to cut fome fheets of thick brown paper, each into about eight parts, making them up into the fhape of a fugar-loaf, and bird-liming the infide of them three or four days before intending to ufe them; putting into each paper, near the bottom, three or four grains of corn, and laying thefe papers up and down the ground, as much as you can, under clods of earth, early in the morning before the pigeons, &c. come to feed. When the pigeons come to feed on the corn, by thrufting in their heads to reach it, they get hood-winked by the paper fticking to their heads, which occafions them to take wing, and fly upright till they have fpent themfelves, when they tumble down and may be eafily taken. But the gun is probably the beft method in fuch inftances.

Pigeon, *Barbary*. See Barb.

Pigeon, *Helmet*. See Helmet.

Pigeon, *Laughing*. See Laugher.

Pigeon, *Mahomet*. See Mahomet.

Pigeon-*Dung*, in *Agriculture*, a manure of the bird dung kind, which is fuppofed to poffefs many valuable properties. It is fometimes turned in like other light fubftances in the fpring, and cofts about one fhilling a bufhel, heaped, in fome diftricts, and about a halfpenny a bufhel more bringing to the land; it is ufed alfo as malt duft, and anfwers in all feafons. See Manure, and Top-dressings.

Pigeon-*Houfe*, in *Rural Economy*, a building, or houfe, erected for the purpofe of keeping and breeding of pigeons, &c. It is fometimes called a dove-cote. In order to erect a pigeon-houfe to advantage, it is neceffary, in the firft place, to pitch upon a convenient fituation, of which none is more proper than the middle of a fpacious court-yard, when it is fheltered, and has a fouthern afpect. With regard to the fize, it muft depend entirely upon the number of birds intended to be kept; but it is better to have it too large than too fmall; and as to its form, the round fhould be preferred to the fquare, becaufe rats cannot fo eafily come at them in the former as in the latter. It is alfo much more commodious; as, by means of a ladder turning upon an axis, it is poffible to vifit all the nefts in the houfe, without the leaft difficulty; which cannot be fo eafily done in a houfe of the fquare form. And in order to hinder rats from climbing up the outfide of it, the wall fhould be covered with tin plates to a certain height, as about a foot and a half; which fhould project out three or four inches at the top, to prevent their getting up more effectually. It fhould be placed at no great diftance from water, that the pigeons may carry it to their young ones, in a proper ftate and more conveniently. Where the houfe is covered with boards, they fhould be well joined together, fo that no rain may penetrate through. And the whole building fhould be covered with hard plafter, and white-wafhed within and without. There muft be no window or other opening in the pigeon-houfe to the eaftward; thefe fhould always face the fouth; for pigeons are very fond of the fun, efpecially in winter. Other coverings are better than boards, as will be feen below. In regard to the nefts or covers, they may confift of fquare holes made in the walls of a fufficient fize to admit the cock and hen to ftand in them; the firft range of thefe nefts being placed at a proper diftance from the ground; and thefe nefts fhould be placed in quincunx order, and not directly over one another. Nefts may likewife be formed in other ways, as will be feen below.

It may be noticed that any lord of a manor may build a pigeon-houfe on his land, but a tenant cannot do it without the lord's licence. And that when perfons fhoot at or kill pigeons within a certain diftance of the pigeon-houfe, they are liable to pay a forfeiture.

And it has been remarked in a late practical work, that where pigeons are bred for the purpofe of deriving profit from them, the pigeon-houfe fhould not only be large and roomy, but be placed in fuch a fituation that the pigeons may be fed with convenience, and without being difturbed by the different operations that are conftantly going on about the

the farm-houfe. The form of the houfe is probably not a matter of much confequence, provided it be not made too deep in the infide; pigeons difliking to have their nefts low down. The floor fhould be clofely laid, and the fides well plaftered, to keep out vermin. The roof may be covered by any convenient and fuitable material, but tiles and flates are by much the beft; thatch, being warm in winter and cool in fummer, may alfo afford a very good covering. The great objection to thatch for dove-cotes is, that the pigeons are apt to fcratch it off; but when the ridge is fecured by ridge-tiles, and very light hurdles are laid on each fide of it, that inconvenience may be prevented. The whole muft be made perfectly fecure againft the entrance of rats and other vermin. Where buildings of this fort are quite detached from the other offices, it is, perhaps, the beft and cheapeft method to erect them on pillars of brick or ftone, or ftrong pofts of wood, about fix or feven feet high from the ground. In the latter cafe the upper parts of the houfe may likewife be principally compofed of wood; and the under part will ferve as a fhed for various ufeful purpofes. If a ftable or cow-houfe the better, as it will have a tendency to keep the pigeons warmer in winter, which is material to their breeding early in the fpring, when they are of moft value in the market. The chief objection againft wood cotes are, their being too cold in the winter, and too hot in the fummer months. It is further ftated, that the apertures or openings for the entrance of the pigeons, fhould always have a fouthern afpect, as they delight in a funny fituation, as obferved above, and they ought not to be too large; the common fize is larger by much than is neceffary. The number of holes muft be regulated by the quantity of birds that are intended to be kept; it is better, however, to have too few than too many; as a great number of holes renders the dove-houfe cold, and in any cafe but few are made ufe of by the pigeons. Above thefe holes a piece of weather boarding, fufficiently large for keeping off the wet, fhould conftantly be fixed up. Thefe boards are generally made fo fmall that they do not keep off the wet effectually from the pigeons. And though it is the general practice to makes fquare holes of board for the pigeons to lay and breed in; a neater method is that of employing fmall wicker bafkets open at the top for this purpofe; thefe bafkets may either be compofed of finer or coarfer materials according to the inclination of the builder, or the expence he wifhes to be at. Nefts made in this way take up but little room, and are readily removed, whenever it is neceffary to clean them, efpecially if they be fixed up in a convenient method for the purpofe. Convenience fhould always be particularly attended to in buildings of this kind.

Pigeon-*Holes*, in *Brick-making*. See Brick.

Pigeon-*Pea*, in *Botany*. See Cytisus.

Pigeon *Creek*, in *Geography*, a river of America, which runs into the Ohio, N. lat. 37° 44′. W. long. 88° 6′.

Pigeon *Houfe*, a name given by Capt. Cook to a mountain of New Zealand, from a fuppofed refemblance. N. lat. 35° 19′. W. long. 209° 42′.

Pigeon *Ifland*, an ifland in Dufky bay, New Zealand, S. of Facile harbour.—Alfo, a fmall ifland in the bay of Bengal, near the coaft of Cicacole. N. lat. 17° 34′. E. long, 83° 23′.—Alfo, a fmall ifland in the Eaft Indian fea, near the coaft of Canara. N. lat. 14° 2′. E. long. 74° 5′.—Alfo, a fortified ifland in Port Royal bay, Martinico.—Alfo, an ifland near the E. coaft of Ceylon; 10 miles N.N.W. of Trincomaly.

Pigeon *River*, a river of the ftate of Tenneffee, which runs into the French Broad river, N. lat. 35° 46′. W. long. 82° 56′.

PIGER Henricus, flothful Harry, a fantaftical name for a flow diftilling chemical furnace; called alfo an *athanor*.

PIGGERY, in *Rural Economy*, a term applied to the place where hogs or fwine are lodged.

In *Plate* XL. *fig*. 1. on *Agriculture*, is feen the plan of one-half of the duke of Bedford's piggery at Woburn Abbey: *a, a, a, a, a, a*, fties; *b, b, b, b, b, b*, troughs; feparated by ftrips of wood generally into fix divifions, but occafionally into a greater number when the pigs are fmall; *c, c, c, c, c, c*, gates which feparate the fties and fhut them up, as fhewn by the dotted curved lines, when cleaned, &c.; *d, d, d, d, d, d*, gutters which convey the urine and liquid filth into the receptacles *e, e*; *f*, a boiler for potatoes, meal, &c.; *g, g, g*, chefts for peas, meal, &c. *Fig*. 2. a fection through the dotted line A B. The doors in cold weather are partially clofed by hatches which turn down on hinges; one of them is fhewn in that ftate at *k*; *l* the boiler. *Fig*. 3. is a fection through the dotted line C D; *m, m*, troughs; *n*, one of the gates; that on the other fide is fuppofed taken off to fhew the door *o*; *p, p*, gutters. *Fig*. 4. a fection of one of the troughs on a larger fcale; *q, q*, the hatches, as turned up in mild weather.

This form of piggery is very neat and convenient for many different purpofes in the rearing and keeping of fwine. See Hog-*ftie* and Swine.

PIGGIN, a provincial term applied to a little pail or tub with an erect handle, for milking in, and other ufes. See Pail.

PIGHIUS, Stephen-Vinand, in *Biography*, a learned antiquary, was born in 1520, at Campen, in Overyffel. He was maternal nephew of Albert Pighius, whofe family name he affumed. A refidence of eight years at Rome gave him an accurate knowledge of the remains of antiquity in that capital. On his return to Germany he attached himfelf to cardinal Granvelle, whom he ferved in the character of fecretary for fourteen years, and finally became a canon regular in his own country, and died in 1604. He obtained a high reputation for antiquarian knowledge, and the purity of his Latin ftyle. He compofed two Roman calendars from fragments in the Capitol, and wrote commentaries on the Fafti. He alfo publifhed "Hercules Prodicius," containing the hiftory and travels of Charles, duke of Cleves, propofing it as a kind of model of the education of a young prince. Some pieces of his writing are inferted in the collection of Gronovius. Moreri.

PIGHTLE, in *Rural Economy*, a provincial term applied to a fmall inclofure or croft.

PIGMATHA, in *Geography*, a town of Ruffia, in the government of Olonetz, on the N. coaft of lake Onerfkoe; 16 miles S. of Povenetz.

PIGMENTS, Pigmenta, preparations in a folid form, ufed by painters, dyers, &c. to impart colours to bodies, or to imitate particular colours.

Thefe require to be mixed with fome fluid, as a vehicle, before they can be employed as paints, except in the cafe of crayons, where they are ufed dry.

When glafs is ftained, or coloured, as in painting on glafs, or for counterfeiting gems, or precious ftones, the pigment is always of a metalline, or a mineral nature.

In the gilding of wood, pigments approaching as near as may be to the colour of gold itfelf are both laid under the gold, and ufed alfo for the colouring of depreffed parts, where gold-leaf cannot be conveniently applied. The fubftance chiefly employed for this purpofe is yellow ochre, the colour of which may be improved by a fmall addition of vermilion or other red powders. See Gilding.

PIGMY, or Pygmy. See Pygmy.

PIGNATA,

PIGNATA, in *Commerce*, a meafure for oil at Naples; 320 pignate being = 16 ftaja = 1 falma = 325 lb. avoirdupois.

PIGNE, in *Geography*, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the diftrict of Monaco; 20 miles N.E. of Nice. The place contains 2285, and the canton 2285 inhabitants, on a territory of $52\frac{1}{2}$ kiliometres, in 1 commune.

PIGNE, in *Botany*. See PINEA.

PIGNEROLA, or PINEROLA, in *Geography*, a town of France, in the department of the Po, late capital of the province of the Four Vallies in Piedmont, near the Clufon, the key of Italy, and fortified; 16 miles S.W. of Turin.

PIGNOLETTI, in *Ichthyology*, a name ufed by many for the *aphyæ cobites*, a fmall fifh of the gobius or fea-gudgeon kind, common in the Mediterranean, and brought to the markets of Rome and Venice. See GOBIUS *Minutus*.

PIGNORIA, LORENZO, in *Biography*, a learned antiquary, was born at Padua in 1591. He was brought up among the Jefuits, and became confeffor to a nunnery, and parifh prieft of St. Lorenzo. A canonry of Trevifo was alfo conferred upon him by cardinal Fr. Barberini. He was in habits of intimacy with many of the moft illuftrious men of his time, and collected a valuable library and cabinet of antiquities. He died of the plague in 1631. His works are highly efteemed; the chief are, "De fervis et eorum apud Veteres Minifteriis;" "Menfa Ifiaca," which is an elaborate commentary upon a famous relic, and three Latin letters to the fenator Domenico Molino. Moreri.

PIGRIN, in *Geography*, a Ruffian fettlement, on the W. coaft of America, in Beering's ftrait. N. lat. 65° 54′. E. long 191° 40′.

PIGRITIA, in *Zoology*. See BRADYPUS *Tridactylus*.

PIGUS, in *Ichthyology*, the name of a fpecies of leather-mouthed fifh, very much approaching to the nature of the carp.

It is of the fame fhape and fize with the common carp, and its eyes, fins, and flefhy palate wholly the fame; from the gills to the tail there runs a crooked dotted line; its back and fides are blueifh, and its belly reddifh; it is covered with large fcales, from the middle of every one of which there rifes a fine, pellucid, and very fharp prickle.

It is a finer fifh than the carp for the table, and is in feafon in the months of March and April. It is caught in lakes in fome parts of Italy, and is mentioned by Pliny, though without a name.

It is a fpecies of cyprinus, according to Artedi, and is diftinguifhed by that author under the name of the cyprinus called *piclo* and *pigus*. He adds, that the tail is forked, and the fcales large; and that in fpring and autumn there grow out of them white pyramidal prickles, which remain about five or fix weeks, and then fall off; the back is of a blackifh-blue, and the belly white, with a faint caft of red. It never grows to more than five or fix pounds; the flefh is well tafted. It is found in the lakes in the northern nations.

PIGWAKKET, in *Geography*, a town of America, in Maine, which runs into the Saco; 5 miles S. of Pigwakket.—Alfo, a town of America, in Maine; 27 miles N.W. of Portland.

PIHLAIS, a town of Sweden, in the government of Wafa; 83 miles S.E. of Wafa.

PIHTIPUDAS, a town of Sweden, in the government of Wafa; 105 miles E. of Wafa.

PIISKER, in *Ichthyology*, the name of a fifh of the muftela kind, ufually called the *muftela foffilis*, or *pifcis foffilis*, the foffile fifh. See COBITIS *Foffilis*.

This feems very much of the kind of the fifgum fifh, and poffibly is no other than the fame fpecies; and poffibly alfo the pæcilia of Schonefeldt is the fame.

PIKE, an offenfive weapon, confifting of a fhaft of wood, twelve or fourteen feet long; headed with a flat-pointed fteel, called the *fpear*. The general length fixed for the pike by moft princes and ftates was, according to fir James Turner, in his "Pallas Armata," written in 1670 and 1671, 18 feet; but he obferves that few exceeded 15.

The name pike is faid to be derived from a bird called by the French *pic*, by us wood-pecker; whofe bill is faid to be fo fharp as to pierce wood like an auger. Du Cange derives it from the bafe Latin *pica*, or *picca*; which Turnebus fuppofes to have been fo called, *quafi fpica*, becaufe refembling an ear of corn: Octavio Ferraro derives it *à fpicula*. M. Fauchet fays, it was the pike that gave name to the Picards, and to Picardy; which he will have to be modern, and to have been framed on occafion of that people's renewing the ufe of the pike; the etymology whereof he fetches from the French *piquer*, *to prick*. But others will have the name *Picard* to have been given that people by reafon of their readinefs to pick quarrels; called in French *piques*.

The pike was a long time in ufe in the infantry, to enable them to fuftain the attack of the cavalry: but it is now taken from them, and the bayonet, which is fixed to the muzzle of the firelock, is fubftituted in its place.

It is ftill ufed by fome officers of infantry under the name of fpontoon.

Pliny fays, the Lacedæmonians were the inventors of the pike. The Macedonian phalanx was evidently a battalion of pike-men.

Father Daniel fays, that pikes are not mentioned in the hiftories of France before the reign of Lewis XI. Pikes were introduced into France by the Switzers. The ufe of the pike was abolifhed in France by a royal ordonnance, iffued in the year 1703; and though the exact period when pikes were laid afide in England has not been afcertained, it appears by the "Gentleman's Dictionary," publifhed in 1705, that the alteration of the pike for the mufket muft have taken place fome time between the years 1690 and 1705.

PIKE, *Half*, in the *Military Art*, is the weapon carried by an officer of foot. It differs from a pike, becaufe it is but eight or nine feet long, and the fpear is fmaller and narrower. See SPONTOON.

PIKE, in *Ichthyology*, a name given by us to the fifh called by authors the *lucius* and *efox*, and by the old Greek writers *oxyrinchus*. See ESOX *Lucius*.

It is faid, that the pike was introduced into England in the reign of Henry VIII. in 1537, when a pike was fold for double the price of a houfe-lamb in February. Befides fifh and frogs, which are its ufual food, it will devour the water-rat and young ducks. It is very fierce and voracious. This fifh is very remarkable for its longevity: we read of one that was ninety years old, and of another, that was not lefs than 267 years old. See *Feeding of* FISH, *Pike*-FISHING, and HUXING.

PIKE, *Land*. See LUCIUS *Terreftris*.

PIKE-*Pearch*. See LUCIO-*perca*.

PIKE, *Sea*. See MERLUCIUS and SUDIS.

PIKE, a provincial word fignifying a fort of ftacklet or load cock of hay, &c.

PIKE, a name given in fome counties to a prong, or what is generally called a fork, ufed for carrying ftraw, &c. from the barn, cocking of hay, &c.

PIKE, a term in the midland diftricts fignifying to glean.

PIKEfering in feveral other particulars. It is a fpecies of CLUPEA; which fee.

The diftinguifhing characters of it are thefe: the body of the pilchard is lefs compreffed than that of the herring, being thicker and rounder; the nofe is fhorter in proportion, and turns up; the under jaw is fhorter; the back is more elevated; the belly lefs fharp; the dorfal fin of the pilchard is placed exactly in the centre of gravity, fo that when taken up by it, the body preferves an equilibrium, whereas that of the herring dips at the head; the fcales of the pilchard adhere very clofely, whereas thofe of the herring very eafily drop off. Pennant.

It is generally found fwimming in vaft fhoals, and is caught in many parts of the Englifh fhores. Its flefh is better tafted than that of the herring. See *Pilchard* FISHERY.

PILCHOWITZ, in *Geography*, a town of Silefia, in the principality of Oppeln; 36 miles S.E. of Oppeln. N. lat. 50° 10′. E. long. 18° 30′.

PILCO MAYO, a town of Peru; 25 miles N.E. of Potofi.—Alfo, a river of South America, which, after a fouth-eaft courfe of about 600 miles, runs into the Parana, by two mouths, between S. lat. 25° 40′ and 26° 20′.

PILE, in *Antiquity*, a pyramid built of wood, whereon were laid the bodies of the deceafed, to be burnt.

PILES, in *Hydraulic Architecture*, are beams of timber, or ftakes of wood, driven firmly into the ground, for various purpofes; as, for forming a firft foundation for buildings, piers of bridges, &c.; in which cafes they are driven quite down into the ground, or are cut off level with its furface, with a view of obtaining a folid bearing for the weight of the ftructure which is to be raifed.

Amfterdam, and fome other cities, are wholly built upon piles. The ftoppage of the breach in the banks of the Thames at Dagenham, was effected by dove-tail piles; that is, by piles mortifed into one another by a dove-tail joint.

Piles are not employed for foundations unlefs the ground is fufpected to be unfound, or when the weight to be borne is exceedingly great. They act to make the foundation folid, by reaching deep into the earth, down to a more fubftantial ftratum than that of the furface. Indeed, the manner of fixing the piles, by driving them by repeated blows of a powerful machine till they will go no farther, enfures that they come to a good bearing. There are inftances of piles being driven down twenty-five feet, before they were thought fufficiently firm.

Piles are alfo ufed for making the faces of wharfs, banks of rivers, piers for the fea, &c. For thefe purpofes they are driven in rows, but only a fufficient depth in the earth to make them ftand firm, and fupport the planking or framing which is fixed againft them. Thefe piles are ufually driven rather in an inclined pofition. For temporary defence againft the water, in laying the foundation of bridges, &c. piles are always required. They are employed in different ways to form an enclofure, or water-tight wall, called a coffer-dam, round the area where the work is to be laid, and from which fpace the water is drawn by pumps. This is the moft difficult of all kinds of piling; becaufe it muft ftand a great height above the ground, have fufficient ftrength to refift the preffure of water, and be perfectly clofe and tight. In navigable rivers detached piles are driven, and very firmly fixed, to mark the enclofures where barges are to lay, and to fender off others from them, as well as to moor them to.

Piles are in general formed of a fquare timber, tapering if the tree happens to be fo, cut to a fharp point at one end, and fhod with iron to enter the ground. The other end was bound by a ftrong iron hoop, to prevent the pile head fplitting by the violence of the blows which drive it down. When they are to be driven quite below ground, fmall trees, if fufficiently ftraight, may be ufed without fquaring; but for coffer-dams fquare piles are always ufed, except that for filling up a row between fuch fquare piles. When they are to touch each other, flat ones, called pile planks, are ufed; they are three or four inches thick, according to the depth of water, and have grooves formed in their adjacent edges, to receive tongues or flips of wood, which make the joints quite tight. To enclofe an area for a coffer-dam, two rows or walls of piles are ufually driven one within the other, at a diftance ufually equal to the depth of water they are driven in, or if the current is rapid, once and a half. The fpace between thefe is filled with clay, fo as to form a mound or rampart of clay, defended on the outfide and infide by wooden walls of piles. To make thefe walls, large fquare piles are firft driven at a diftance of ten or twelve feet afunder, in the line of the intended range of the dam; horizontal tye beams are then extended from one pile to the next, on the infide, each tye being notched into the piles, fo that its outer edge is in a line with the infide of the groove for the plank piles, which are to be driven down to fill up the fpaces between the piles, and will be guided by thefe tyes to ftand exactly vertical, and in a ftraight line. The firft plank piles are begun to be fixed adjacent to the main piles, and thus they proceed from both ends of the fpace between the piles, till the planks meet in the centre, where the laft plank is inferted, and being formed rather wedge-like, makes all the reft tight. The pile planks are cut inclined, or wedge-like on one fide only, to form the point, by which means the point is the line of one of the edges of the plank. When a plank pile is to be driven adjacent to another, this edge is applied to the one already fixed, and then as it is driven, the inclined or wedge-like edge entering the ground, caufes the pile to approach, and prefs very clofe to its neighbour, and it is chiefly by this means they are made to fit water-tight. The fillets are made by fpiking a ledge or ruler of wood faft upon the edge of one plank, and a groove of correfponding depth and width is ploughed in the edge of the adjacent plank to receive it. Many different machines are ufed to drive piles into the ground; fome of them are worked by a great number of men, who raife a heavy weight a fmall height, and let it fall upon the pile, till, by reiterated blows, they drive it to the required depth. The machine employed is extremely fimple. A long thick plank of wood is fixed up clofe to the pile, having a mortife through the upper end, in which a pulley is fitted; a rope goes over this to fufpend the rammer, which is a large block of hard wood, properly hooped, to prevent it from fplitting. In rifing and falling, it flides againft the face of the plank, and is guided by irons, which are fixed to the ram, and are bent round the edges of the plank in the manner of hooks. The plank, when placed upright, is fecured by guy ropes, in the manner of the maft of a fhip; the end of the great rope which fufpends the ram, has ten or twelve fmall ropes fpliced into it, for as many men to take hold, and work it by; they raife the ram up two or three feet by pulling the ropes all together, and then letting them go, the ram falls upon the pile head. When the pile becomes firm enough to caufe the ram to rebound, they take care to pull the ropes inftantly after the blow, that they may avail themfelves of the leap it makes.

This is the fimpleft form of the machine. Others, inftead of a plank, have two upright beams attached together, at fuch a diftance afunder, as to leave an opening between them, for the reception of a piece of wood which is affixed to the ram, and by this means it is guided. Inftead of guy ropes, thefe these are usually fixed upon a base, consisting of a triangular frame, upon one angle of which the uprights are erected; and from the other two angles, braces arise, which are so inclined as to reach the uprights at half or two-thirds of their height to steady them. This plan is very convenient for driving piles in corners; but for driving rows, it is more advantageous to have the uprights fixed at the middle of one side of the triangular base, and have stays from all the three angles. A machine of this kind, with a ram of beech four feet long and one foot square, may be worked by ten or twelve men, at the rate of twenty-four blows *per* minute, and fixes the pile very quickly.

To estimate the force of the rammer made use of to drive piles, its weight ought to be multiplied into the velocity it acquires in falling. Thus, if a rammer which weighs 500lb. be let fall from four feet, it will fall that height in half a second, and have at the time of percussion a velocity capable to carry it uniformly eight feet in half a second, without any farther help from gravity; so that we must multiply 500 by 16, or its weight by the number of feet it would fall in a second, and the product 8000 gives the momentum of the stroke. If a capstan, pullies, or windlass, be made to raise the rammer to a considerable height, and then, by an easy contrivance, loosen it at once from its hook, the momentum of the stroke will always be as the square root of the height from which the rammer fell.

Notwithstanding the momentum, or force of a body in motion, is as the weight multiplied by the velocity, or simply as its velocity, when the weight is given or constant; yet the effect of the blow will be nearly as the square of that velocity; the effect being the quantity the pile is driven into the ground by the stroke. For the force of the blow, which is transferred to the pile, being destroyed in some certain definite time by the friction of the part which is within the earth, which is nearly a constant quantity, and the spaces in constant forces being as the squares of the velocities; therefore, the effects which are those spaces sunk, are nearly as the square of the velocities, or, which is the same thing, nearly as the heights fallen by the ram or hammer to the head of the pile. See upon this subject Leopold, Belidor, also Desaguliers's Exper. Philos. vol. i. p. 336, and vol. ii. p. 417, and Philos. Trans. 1779, p. 120.

For large works, such as bridges, &c., the piles are driven by a different kind of machine: this has a very heavy iron ram, with mechanical powers, by which it is raised to a considerable height, and then let fall, instead of continually repeating small blows. These are sometimes worked by horses, or steam-engines: see elevations of one, in *figs.* 1. and 2, *Plate* XXXV. *Mechanics.* A, A, are the uprights, erected on the frame B, and supported by the braces C; they are connected by the cross feet *a* at bottom, and the piece D at top; in this the pulley *b* for the rope *d* is fitted. Fillets of iron are fixed withinside the uprights A, A, and enter grooves made in the edges of the great iron ram E, which is thereby guided as it rises and falls: F is a piece, called the follower, (see *figs.* 3 and 4.); it is a wooden block, sliding between the uprights, and mortised to receive the iron tongs *e*, which take hold of an eye upon the top of the cast iron ram: the rope is attached to the follower by an iron loop *f*, through which the centre pin of the tongs passes. On the base, *a* B, of the machine an iron frame is bolted, to contain the windlass G, on which the rope *d* winds. On the end of the windlass a cog-wheel, *g*, is fixed, and a pinion upon the axis, *h*, engages its teeth. Motion is given to the spindle *h* by the winches *k*, fixed on each end of it, and the fly-wheel, *l*, regulates its motion, when turned by two men at each handle. The pile is of course included in the space between the two uprights, A, A, before it is driven down; and the ram, being engaged by the tongs *e*, is drawn up by turning the handle, *k*, till the tails, *n*, of the tongs come to the inclined planes *m*, *fig.* 1: by these they are closed together, which opens the lower ends, disengages them from the eye of the ram, and it falls upon the head of the pile immediately. The men at the handles shift the spindle *h* endways, which disunites the pinion from the wheel, and then the weight of the follower, F, runs back the windlass G, and descends till its tongs take hold of the ram, ready to take it up again. The inclined planes, *m*, are not fixed to the uprights A, A, but are connected together by pieces of wood, which embrace the uprights, and these have holes through them to receive iron bolts, which also pass through the uprights. By this means the inclined planes can be shifted, to set them at any required height, that they may, by discharging the ram at the proper height, give a blow proportioned to the pile which is to be driven by it. The tongs are sometimes made with rollers in the ends *n*, *n*, as shewn in *fig.* 12, that they may act more easily in the inclined planes. Other machines have a kind of latch, shewn in *fig.* 11, instead of the tongs; in this *f* represents the iron loop for the rope; the centre pin of it passes through the latch *r s t*, which catches the eye of the ram by the hook *t*, and is discharged by the line *r*, when the men snatch it. The weight *s* is to cause the hook to catch; the loop *f* is attached to a wooden follower, which guides it between the uprights.

Machines of this kind are frequently actuated by steam-engines. A pulley, which is fixed on the end of the spindle *h*, in place of the handle *k*, receives an endless rope from some wheel put in motion by the engine; one man then attends it, to throw the spindle endways at the proper time, to permit the descent of the follower; but we have seen one in which levers, and a connecting rod from the inclined plane, *m*, were used to disengage the spindle the moment after the follower discharges the ram; by adopting these means much expence of labour would be saved, as the same steam-engine which is afterwards to be employed in pumping out the water of the coffer-dams, would drive the piles for them and the foundations.

The piles of the works of Westminster-bridge, whilst it was building, were driven by a horse-machine invented by Mr. Valoue. A pair of the uprights, such as represented at *figs.* 1 and 2, but thirty feet high, were erected at one end of a frame, which supported a vertical shaft, turned round by the horses, and the framing was of course large enough to admit a circular walk of sufficient size for them to work in, when they drew the ends of arms or levers projecting from the vertical shaft. The whole was erected upon a platform, which was built over a barge in the manner of a deck. The vertical shaft had a wheel or drum upon it, to wind up the rope of the follower, and it was in the construction of this part that the invention lay. A section of the upper part of the vertical shaft and drum is given in *fig.* 8, and a plan in *fig.* 9. Here A is the great upright shaft, or axle, turned by the horses attached to the levers, which are not shewn. The cog-wheel, B, turns the pinion X, having a fly, O, at the top to regulate the motion, and to act against the horses, and keep them from falling, when the heavy ram is disengaged to drive the pile down into the earth in the bottom of the river. The drum, C, is loose upon the axle of the shaft A, but is locked to the wheel, B, by the bolt Y. On this drum the great rope, H, is wound, one end of it being fixed to the drum, and the other to the follower, passing over proper pulleys. In the follower are contained the tongs, which take hold of the ram, by the staple for drawing it up, in the same manner as described in *fig.* 2;

D is a ſpiral, or fuſee fixed to the drum C, on which winds the ſmall rope T: it goes over a pulley, and has a ſmall counterpoiſe hung to the end of it, which hinders the follower from accelerating as it goes down to take hold of the ram; for as the follower tends to acquire velocity in its deſcent, the line, T, winds downwards upon the fuſee on a larger and larger radius, by which means the counterpoiſe acts ſtronger and ſtronger againſt it; and ſo allows it to come down with only a moderate and uniform velocity. The bolt, Y, locks the drum to the great wheel, being puſhed upwards by the ſmall lever 3, which paſſes through a mortiſe on the ſhaft A, and turns upon a pin; the lower end of the bolt is guided by paſſing through a piece of wood, 6, fixed into the great ſhaft, and the upper paſſes through an arm of the wheel; the lever, 3, has a weight, 4, which always tends to puſh up the bolt, Y, through the wheel into the drum; G L is the great lever, turning on the centre *m*, and reſting its end, G, upon the forcing bar 5, which goes down through a hollow in the ſhaft A, and bears upon the little lever 3. The other end of the lever, L, is long enough to reach to the uprights, and has there a ſmall rope, extended from the end of it up to the inclined planes, ſo that the follower, when drawn up to the higheſt, draws this rope, and raiſes the long end, L, of the lever, depreſſing the other, and the forcing bar 5. By the horſes going round, the great rope, H, is wound about the drum C, and the ram is drawn up by the tongs in the follower, till they come between the inclined planes, which, by ſhutting the tongs at the top, open them below, and ſo diſcharge the ram, which falls down between the uprights upon the pile, and drives it by a few ſtrokes as far into the ground as it can go, or as is deſired; after which the top part is ſawed off cloſe to the mud, by an engine for that purpoſe. Immediately after the ram is diſcharged, a piece upon the follower takes hold of the rope, which raiſes the end, L, of the lever L G, and cauſe its end, G, to deſcend, and preſs down the forcing-bar, 5, upon the little lever, 3, which by drawing down the bolt Y, unlocks the drum, C, from the great wheel B; and then the follower being at liberty, comes down by its own weight to the ram; and the lower ends of the tongs ſlip over the eye of the ram, the weight of their heads cauſing them to fall outwards, and faſten upon it; then the weight, 4, puſhes up the bolt, Y, into the drum, which locks it to the great wheel, and ſo the ram is drawn up as before.

As the follower comes down, it cauſes the drum, C, to turn backward, and unwinds the rope from it, while the horſes, the great wheel, pinion X, and fly, go on with an uninterrupted motion; and as the drum is turning backward, the counterpoiſe is drawn up by its rope, T, winding upon the ſpiral fuſee D.

There are ſeveral holes in the under ſide of the drum, and the bolt, Y, always takes the firſt one that it finds, when the drum ſtops by the falling of the follower upon the ram, till which ſtoppage the bolt has not time to ſlip into any of the holes. But the ſame effect is more certainly produced by a crooked lever, *t*, *fig.* 9, fixed on the framing R, over the end of the vertical ſhaft; one end of this has a roller, which is preſſed upon by the great rope, H, the other end holds down the catch, 5, of the forcing-bar, but as ſoon as the great rope ſlackens, it retires, and gives liberty to the ſmall lever, 3, to puſh up the bolt. As long as the great rope has a tenſion upon it, to ſupport the weight of the ram or follower, the crooked lever is kept in cloſe contact with the forcing-bar, and when that is depreſſed, (to diſcharge the bolt Y,) by locking over its catch, 5, the crooked lever keeps it down, till the follower touches the ram; the great rope then ſlackens, and the ſpring, *v* H, diſcharges the crooked lever from the catch of the forcing bar, and gives liberty to the ſmall lever, 4, to puſh up the great bolt, and to lock the drum to the great wheel, and the ram is drawn up again as before.

The peculiar advantages of this engine are, that the weight of the ram, or hammer, may be raiſed with the force of horſes inſtead of men; that when it is raiſed to a proper height, it readily diſengages itſelf, and falls with the utmoſt freedom; that the forceps or tongs are lowered down ſpeedily, and inſtantly of themſelves again lay hold of the ram, and lift it up; on which account this machine will drive the greateſt number of piles in the leaſt time, and with the feweſt labourers.

The piles at Weſtminſter bridge, when driven by the above machine till they were quite firm, were cut off, under water, by a machine, to be level with the ſurface of the ground to found the piers upon. This machine conſiſted of a framing which was adapted to fit upon the upper part of the pile, and could be fixed faſt thereto. The lower part of this frame formed guides for the ſaw, which reciprocated horizontally at a certain depth beneath the top of the pile, and had weights to cauſe it to advance up to the cut. The ſaw was put in motion by ropes from each end, which were conducted, over proper pullies, to two men ſtanding on a float or raft at the ſurface. After fixing the machine, before the ſawing was begun, the whole machine was ſuſpended by a tackle, which therefore took up the top part of the pile with the machine as ſoon as it was cut off. This was the invention of Mr. Etheridge, carpenter to the works at Weſtminſter bridge; it was very effective, as the time employed in cutting off a fir pile of 14 or 16 inches ſquare, in ten feet depth of water, was ſeldom more, and often leſs, than a minute and a half. A machine, more convenient than this in its application, and not leſs effective, has been ſince invented by Mr. Foulds, to whom the Society of Arts preſented a gold medal for the invention; ſee *figs.* 5 and 7. A A B is the external frame, conſiſting of four parallel rails A, framed into two others, B, at right angles, with proper croſs pieces to unite them, and inclined to ſtrengthen the whole; within this frame a ſecond, or internal frame, D E, is ſituated; like the other, it has four parallel pieces, D and E, connected together into one frame by croſs pieces; at the top it has two pieces *a*, *a*, which reſt upon the beam B, and ſuſpend its weight, and on theſe it is capable of ſliding backwards and forwards between B B, always preſerving its parallelifm, becauſe it is moved by the racks, *d*, *d*, affixed to it, one at top, and the other at the bottom; the pinions for both are fixed on a vertical axis *e*, ſupported in the external frame; therefore, by turning the handle *r*, the internal frame with the ſaw is advanced to the pile, as at K, *fig.* 6. The ſaw itſelf is ſuſtained in a frame L, *fig.* 7, which fits, in the manner of a ſaſh frame, between the two beams, D, of the internal frame, and has racks, *f*, *f*, (dotted) behind it, which work in pinions on an axis *g*, extended acroſs the frame, and by the handle, *y*, of this it is capable of being drawn up and let down, or detained at any height by a ratchet-wheel and click *x*; the ſaw, *m*, is fixed upon a ſpindle N, ſupported in bearings on the frame L, and turned by the handle, R, at the top; the ſaw is connected with the ſpindle by a piece of iron *p*, having a mortiſe through it for the reception of the ſpindle, to which it is faſtened by a nut beneath: by this means the ſaw's edge may be advanced as the work goes on.

In uſing this machine, the beams, B, are fixed acroſs a barge, which is ballaſted till they are horizontal, and the ſpindle of the ſaw is therefore vertical in this ſtate; it is moored with her ſide againſt the pile, K, to be cut off, as

ſhewn

ſhewn by the dotted line V, *fig*. 6; then by the rack and pinion *f g*, the ſaw is adjuſted in height to the level where the pile is to be cut; by the handle *r* it is advanced to the pile K, whilſt by the other handle, R, the ſaw is kept in continual motion backwards and forwards, till the pile is cut through, and the piece is taken into the barge, which proceeds to cut off the next by the ſame means. By this machine temporary piles, which are uſed in coffer-dams, may be cut off level with the bottom, when the work is finiſhed, which is a very ſuperior method to drawing them up out of the ground, as is the uſual practice, becauſe this muſt neceſſarily make a deep ditch or trench all round the pier or foundation, and tend to looſen the ground. To draw piles out of the ground when they have been driven faſt, requires a very great force. There are different methods of exerting this force: one for drawing them in water, is by having a very ſtrong barge, with a windlaſs at one end to receive a ſtrong chain, which is paſſed ſeveral times round the head of the pile, and made faſt to the barge; two long beams are laid upon the barge to form a railway for a ſmall waggon to run upon from one end of the barge to the other, and it is loaded with ſtones of ſeveral tons weight; when this is wheeled to one end of the barge, it will of courſe depreſs it in the water, elevating the other; then, in this ſtate, the loweſt end of the barge is chained to the pile by putting a very large bolt through it, and paſſing a chain round the pile under this bolt a great many times; the carriage is then wheeled to the other end of the barge by a windlaſs and rope; this tends to raiſe the end to which the pile is fixed; and when the carriage is ſo far advanced that it exerts a ſufficient power, it will draw up the pile if the chain is properly fixed: the carriage is now returned to draw another pile.

A plan has been adopted at the new bridge now building acroſs the Thames at the Strand, for drawing the uſeleſs piles by one of Mr. Bramah's hydroſtatic cylinders. This is repreſented in *fig*. 10, where A is ſuppoſed to be the top of a range of piles forming the coffer-dam, and B the pile which is to be drawn. A chain, *a*, is made faſt to the pile, and carried many times round a large beam C D, the end, D, of which reſts upon a fulcrum, or ſupport E, conſiſting of a block, ſupported on the head of a neighbouring pile, &c. F is a block of wood, ſcrewed together in two places, and incloſing between them a caſt iron cylinder *b*, into which is fitted the piſton, or cylinder *d*, the joining being made tight by a collar of leather; *e* is a ſmall copper pipe, communicating with the cylinder, and alſo with a ſmall forcing pump, the piſton, *f*, of which, is actuated by the lever *g h*; the pump is fixed upon the top of a ſmall ciſtern, *k*, to contain water. Now by working the lever of the pump, water is injected into the cylinder *b*, and protrudes the piſton, *d*, from it with a force proportioned to the force exerted upon the lever, in the ſame degree as the areas of the pump to that of the cylinder multiplied by the proportions of the lever *h*. (See this principle more fully illuſtrated under Machinery, and Press, *Hydroſtatic*.) By this means the power of one or two men is increaſed to ſuch a degree, as to draw up the largeſt pile; the copper pipe, *e*, is made to unſcrew at ſeveral joints, which are provided with leather, to make them tight; by this means the pump is ſeparated when the machine is to be removed. As it has no connection with the beam or lever D, the cylinder is frequently employed in the manner of a hand jack, for any purpoſes where enormous weights are to be lifted for a ſmall ſpace; the collars of leather are the ſame as are uſed in the preſſes. The ſame figure alſo ſhews a very complete way of catching faſt hold of the pile, inſtead of putting a bolt through the pile head to ſtop the chain under: it is ſimply a ſtrong iron ring, *l*, large enough to drop over the pile looſely, and having a ſtrong ſhank or eye, *m*, projecting from it to run the chain through; and when this is drawn, the ring jambs ſo forcibly upon the wood of the pile, as to draw it out of the ground rather than ſlip off, for it holds faſter in proportion to the force.

The theory of Mr. Valoue's engine depends on the following principles, *viz*. 1. If the reſiſtance of the ground, and the maſſes of the piles be equal, the depths to which they will be driven with a ſingle blow will be as the product of the weight of the ram into the height through which it falls.

2. If the maſſes of the ram, and heights through which it falls are both equal, the depths to which the piles will be driven, will be in the inverſe ratios of the maſſes of the piles into the ſuperficies of that part of them which is already immerſed in the earth.

3. If all theſe things be unequal, the depths will be in a ratio compounded of the direct ratio of the heights through which the ram falls into its maſs, and the inverſe ratio of the maſs of the pile into its immerſed ſuperficies.

4. If the weights of the ram be equal, and alſo the weights of the piles, the depths to which they will be driven will be as the heights through which the ram falls directly, and the immerſed ſuperficies of the piles. Or, becauſe the immerſed ſuperficies of the piles are as the depths through which they are already driven into the earth, theſe depths are ſimply as the ſquare roots of the heights through which the ram falls.

Theſe principles are founded on the general ſuppoſition that the ſpace through which the weight falls is eſtimated by the product of its maſs into the ſquare of its velocity, or into the height through which it falls.

Hence it is inferred, that the diſtance through which a pile will be driven by each ſucceeding blow will be leſs and leſs, as the ſuperficies of that part of the pile which is immerſed in the ground increaſes; and, conſequently, that there is a certain depth, beyond which a pile of a given maſs and ſcantling cannot be driven; the maſs of the ram and the height through which it falls at firſt being aſſigned. It appears alſo, that the loading the pile with weights, and thereby increaſing its maſs, will be ſo far from accelerating its deſcent, that it will abſolutely retard it. See ſome curious obſervations on the ſtructure and operation of this engine by Mr. Bugge, profeſſor of aſtronomy and mathematics in the academy of Copenhagen, &c. in the Phil. Tranſ. for 1779, vol. lxix. part i. art. 12.

Pile is alſo uſed, among *Architects*, for a maſs or body of building.

Pile, in *Artillery*, denotes a collection or heap of ſhot or ſhells, which are uſually piled up by horizontal courſes into a pyramidal form, the baſe being either an equilateral triangle, a ſquare, or a rectangle. In the triangle and ſquare, the pile terminates in a ſingle ball; but in a rectangle, in a ſingle row of balls. In the triangle and ſquare piles, the number of horizontal rows, or the number counted on one of the angles from the bottom to the top, is always equal to the number counted on one ſide, in the bottom row. In triangular piles, each horizontal courſe is a triangular number, produced by taking the ſucceſſive ſums of the numbers 1 and 2; 1, 2, and 3; 1, 2, 3, and 4, &c.; and the number of ſhot in a triangular pile is the ſum of all the triangular numbers taken as far, or to as many terms, as the number in one ſide of the bottom courſe. In order to obtain the number in a triangular pile, count the number in the bottom row, and multiply that number more two by that number more

more one; and the product multiplied by one-fixth of the faid number will be the whole fum required.

In fquare piles, each horizontal courfe is a fquare number, produced by taking the fquare of the number in its fide; and the number of fhot in a fquare pile is the fum of all the fquares, taken from one as far as the number in the fides of the bottom courfe. To find the number, count the number in one fide of the bottom courfe; to that number add one, and to its double add one; multiply the two fums together, then their product being multiplied by one-fixth of the faid number, will give the required number of fhot in the pile.

From the exemplification of thefe rules, it would appear, that when room is wanted, it is moft convenient to ftow the fhot in triangular piles; for on the equilateral triangle, which is lefs than half the area of a fquare of one of its fides, there can be piled a greater number than half of thofe that can be raifed on the fquare: and the height of a fquare pile is fomewhat lefs than that of a triangular one; becaufe a fhot will fink lower in the fpace between four others, than between three others, when they are of equal diameter.

In rectangular piles, each horizontal courfe is a rectangle, the upper one being one row of balls; and every fuch oblong pile may be confidered as confifting of two parts, one a fquare pyramid, and the other a triangular prifm. To find the number of fhot in a rectangular pile, take the difference between the number in length and breadth, in the bottom courfe; multiply the number in breadth, more one, by half the breadth; the product multiplied by the faid difference will give the number in the prifmatic pile; upon the fquare of the breadth, find the number in a pyramidal pile; and the fum of thefe two piles will give the number required. See Caliber.

To Pile *Arms*, in *Military Language*, is to place three mufkets with fixed bayonets in fuch a pofition with regard to one another, that the butts fhall remain firm in the ground, and the muzzles lie clofe together in an oblique direction. This method has been adopted to prevent the injury which was formerly done to mufketry, when the cuftom of grounding the firelock prevailed. Every recruit fhould be taught how to pile arms before he is difmiffed the drill.

Pile, *Pila*, in *Coinage*, denotes a kind of puncheon, which, in the old way of coining, with the hammer, contained the arms, crofs, or other figure and infcription, to be ftruck for the reverfe of the fpecies.

Accordingly, we ftill call the arms-fide of a piece of money the *pile*, and the head the *crofs*; becaufe, in the ancient monies, a crofs ufually took the place of the head in our's.

Hence alfo the game of *crofs* and *pile*.

Some will have it called *pile*, *pila*, becaufe on this fide, in our ancient coins, there was an impreffion of a church built on piles. Scaliger, with more probability, derives it from the old French word *pile*, *a fhip*. Vide prima Scaligerana, in voc. Nummus Raticus, p. 115.

In fome ancient writings, *pila* is ufed to fignify the particular figure, or impreffion of money. Thus Fleta: he who brings an appeal of robbery, or theft, againft another, muft fhew the certain quantity, quality, price, weight, number, meafures, value, and pile.

Pile, in *Heraldry*, is an ordinary, in form of a point inverted, or a ftake fharpened; contracting from the chief, and terminating in a point towards the bottom of the fhield, fomewhat in manner of a wedge.

It is formed, probably, in imitation of the Roman pilum, which was a tapering dart, about five feet long, and fharpened at the point with fteel.

The pile is borne inverted, engrailed, &c. like other ordinaries; and iffues indifferently from any point of the verge of the efcutcheon. He beareth a pile gules, by the name of Chandois.

Pile, in *Rural Economy*, a fharpened piece of wood driven down into the ground, to protect the banks of rivers, or other fimilar purpofes. It fhould be ftrong, and well driven in. See Pile, *fupra*.

Pile, a provincial word applied to the breaking off the awns of threfhed barley.

Pile *of Grafs*, a blade or fmall bit of grafs.

Pile-*Planks*, are planks whofe ends are fharpened, to drive into any canal or water, clofe to each other, in order to form a ftank, by which the water may be ftopped and difcharged. See *Plate* IV. *Canals*, *fig.* 30.

Pile-*Sheeting* is the fame with *dove-tail piling*.

Pile-*Worms*, are a kind of worms found in the piles of the fea-dikes in Holland. Thefe worms are of various fizes: fome of the young ones are not above an inch or two in length; but others have been found thirteen or fourteen inches long.

The heads of thefe creatures were covered with two hard fhells or hemicrania, which together form a figure refembling an auger, and with which they bore the wood. The beft remedy againft them is, to perforate the piles with many fmall holes, about an inch afunder; then it muft be done over with a varnifh in the hotteft fun; and while the varnifh is hot, brick-duft muft be ftrewed over it; and this being feveral times repeated, the pile will be covered with a ftrong cruft, impenetrable to all infects. See a farther account of thefe creatures in Phil. Tranf. N° 455, fect. 5.

PILEÆ, a name given by fome authors to a genus of echinodermata.

PILENTUM, among the Romans, an eafy kind of chariot, ufed by the Roman ladies at games and religious proceffions.

PILES, in *Surgery*. See Hemorrhoids.

Piles, *Liniment for the*. See Liniment.

PILESGROVE, in *Geography*, a town of America, in New Jerfey, and county of Salem, containing 1756 inhabitants.

PILETTUS, in our *Ancient Foreft Laws*, an arrow which had a round knob a little above the head, to hinder it from going far into the mark.

From the Latin *pila*, which fignifies any round thing like a ball. "Et quod foreftarii fui non portabunt fagittas barbatas, fed pilettos." Charta Rogeri de Quincy.

PILEUS, in *Roman Antiquity*, was the ordinary cap or hat worn at public fhows and facrifices, and by the freed-men.

It was one of the common rewards affigned to fuch gladiators as were flaves, in token of their obtaining their freedom. See Rudis.

Pileus *Prefbyteri*, in *Botany*, a name given by fome writers to the euonymus or fufanus, a fhrub which grows in our hedges, and bears a fquare fruit, fomewhat refembling the cap worn by fome orders of priefts.

PILEWORT. See Ranunculus.

PILFUNTE, in *Geography*, a town of Abafcia, on the Black fea; 16 miles S.S.W. of Anakopia.

PILGERRUN, or Pilgrim's *Reft*, a Moravian town of Pennfylvania; 140 miles N.W. of Pittfburg.

PILGRAM, or Peldrzimow, a town of Bohemia, in the circle of Bechin. N. lat. 49° 28′. E. long. 15° 7′.

PILGRIM, one who travels through foreign countries to vifit holy places, and to pay his devotion to the relics of dead faints.

The

The word is formed from the Flemifh *pelgrim*, or Italian *pelegrino*, which fignifies the fame; and thefe originally from the Latin *peregrinus*, a *ftranger*, or *traveller*.

The humour of going on pilgrimage anciently prevailed exceedingly, particularly about the time of the croifades. Pilgrimages were moft in vogue after the end of the eleventh century, when every one was for vifiting places of devotion, not excepting kings and princes themfelves; and even bifhops made no difficulty of being abfent from their churches on the fame account. The places moft vifited were Jerufalem, Rome, Compoftella, and Tours; but the greateft numbers reforted to Loretto, in order to vifit the chamber of the bleffed Virgin, in which fhe was born, and brought up her fon Jefus, till he was twelve years of age.

This chamber, it is pretended, was carried by angels into Dalmatia, about the year 1291, and afterwards in the fame manner tranfported to Loretto, where a magnificent cathedral is built over it. In this chamber is the image of the bleffed Virgin, almoft covered with pearls and diamonds; and round the ftatue there is a kind of rainbow, formed of precious ftones of various colours. Five hundred thoufand pilgrims have fometimes reforted to this houfe in one year, in order to pay their devotions before this glorious image.

Several of the principal orders of knighthood were eftablifhed in favour of pilgrims going to the Holy Land, to fecure them from the violences and infults of the Saracens and Arabs, &c.

Such were the orders of the knights Templars, the knights Hofpitalers, knights of Malta, &c.

The Mahometans are commanded in the Koran (chap. 2, 3. 22.) to perform a pilgrimage to Mecca. This is one of the capital points of their religion, and therefore a prodigious cavalcade of pilgrims annually goes thither, in the company of thofe who are fent with the grand feignior's prefents to the tomb of Mahomet.

So ftrictly is this duty enjoined, and fo neceffary is the performance of it, that, according to a tradition of Mahomet, he who dies without performing it may as well die a Jew, or a Chriftian. For an account of thefe pilgrimages, fee CAABA, CARAVAN, and MECCA.

PILHANNAW, in *Ornithology*, a name given by the Indians to a bird found in the forefts, on the back of fome of our American plantations.

It is a bird of prey, very large and bold. It is defcribed by Joffelin as four times as big as our gofhawk, and having a remarkable large head. All the birds are terrified at its approach; but it principally feeds on quadrupeds, as young fawns, and the like.

PILIATCHIN, in *Geography*, a cape on the eaft coaft of Ruffia, in the Penzinfkoi fea; 272 miles E.N.E. of Ochotfk. N. lat. 60° 10'. E. long. 155° 14'.

PILIMICTIO, a word ufed by feveral authors to exprefs a difcharge of fmall and long filaments, which refemble hairs, among the urine.

PILING. See PALLIFICATION.

PILING-*Iron*, a name provincially applied to a tool ufed in breaking off the awns of barley, and fometimes the tails of oats; an operation which with the farmers is called piling barley, and fometimes faultering it.

PILIO, in *Geography*, a town of Thibet; 67 miles N. of Tourfan Hotun.

PILIS, a town of Hungary; 8 miles S.E. of Gran.

PILKALLEN, a town of Pruffian Lithuania; 64 miles E. of Königfberg. N. lat. 54° 45'. E. long. 22° 57'.

PILKOPEN, a town of Pruffia, in the province of Samland, feated on a mountain, where the ancients placed an idol, called "Pilkob," which they worfhipped; 30 miles N. of Königfberg.

PILKINGTON, a townfhip of England, in Lancafhire, containing 5786 inhabitants, including 3824 employed in trade and manufactures; 3 miles S. of Bury.

PILL, or CROCKERN *Pill*, a town, or rather village, of England, in the county of Somerfet, on a point of land at the mouth of the Avon, where it joins the Severn at Kingroad, inhabited chiefly by mariners and pilots, who are employed in navigating veffels up the river, and down the Briftol Channel; 12 miles below Briftol.

PILL, *Pilula*, in *Pharmacy*, a form of medicine, taken dry, refembling a little ball; invented in favour of fuch as cannot well take ill-tafted medicinal draughts; as alfo to keep in readinefs for occafional ufe without decaying.

Extracts, when not too hard, may be formed into pills, without any addition; but they are more generally compofed of either vegetable, or earthy, or metallic powders, combined by means of fyrup into a coherent mafs. Salts may alfo be formed into pills, thofe that are deliquefcent excepted; and when efflorefcent falts are ufed, they fhould be firft freed from the water of cryftallization; becaufe the pills formed with uneffloref ced falts, which are apt to effloref ce, fall into powder as they dry. The maffes, which are kept prepared for the formation of pills, fhould be preferved in covered pots, wrapped in bladders, and occafionally moiftened.

No medicine that is intended to operate quickly ought to be made into pills, as they often lie for a confiderable time in the ftomach before they are diffolved, fo as to produce any effect.

Pills are of various kinds, anodyne, fomniferous, laxative, aperitive, hyfteric, antinephritic, &c.; but they are principally cathartic.

The bafis of cathartic pills is ufually aloes; with which are mixed agaric, turbith, hermodactyls, fenna, rhubarb, colocynth. See EXTRACTUM *Catharticum*.

Pills are ufually wrapped up in leaf-gold, wafer-paper, or the like, to prevent their ill tafte being perceived; but as fimple dry powders, as fubcarbonate of magnefia or ftarch, anfwer all the purpofes of this covering, it is now laid afide.

PILLS, *Compound Aloetic*, are to be prepared, according to the directions of the London difpenfatory, by beating together, into an uniform mafs, one ounce of extract of fpiked aloes, half an ounce of extract of gentian, 40 minims of oil of carraway, and a fufficient quantity of fyrup. The aloetic pills of the Edinburgh Pharmacopeia confift of equal parts of Socotorine aloes in powder and foap, beaten with fimple fyrup into a proper mafs for pills. The pills of aloes and ginger of the Dublin Pharmacopeia are compofed of an ounce of hepatic aloes, a dram of ginger-root in powder, half an ounce of foap, and half a dram of effential oil of peppermint: the aloes and the ginger are rubbed together into a powder, and then the foap and oil are added, fo as to form a mafs. Thefe are ufeful pills, and adminiftered with advantage for obviating the habitual coftivenefs of the fedentary, and of leucophlegmatic habits. The dofe is from grs. x to grs. xv, or more.

PILLS *of Aloes and Affafœtida* of the Edinb. Ph., confift of equal parts of Socotorine aloes in powder, affafœtida, and foap, beaten into a mafs with mucilage of gum arabic. Thefe pills are anodyne and cathartic, and have been found ufeful in dyfpepfia, attended with flatulence. The dofe is grs. x, given twice a day.

PILLS *of Aloes with Myrrh*, are formed, according to the Lond. Ph., of two ounces of extract of fpiked aloes, of an ounce

ounce of ſaffron, and the ſame quantity of myrrh, and a ſufficient quantity of ſyrup: the aloes and the myrrh are rubbed into powder ſeparately, and then all the ingredients are beaten together into an uniform maſs. According to the Dub. Ph., half an ounce of myrrh and an ounce of hepatic aloes are pulveriſed ſeparately; then two drams of ſaffron and half a dram of oil of carraway being added to them, all the ingredients are beaten together into a maſs. The ſame pills of the Edinb. Ph. are compoſed of four parts of Socotorine aloes, two parts of myrrh, and one part of ſaffron, beaten into a maſs with ſimple ſyrup. Theſe pills have been long uſed to ſtimulate and open the bowels in chlorotic, hypochondriacal, and cachectic habits. The doſe is from grs. x to ℈j, given twice a day.

Pills of this kind are deſcribed by Rhazis, the Arabian, who aſcribes the original form to Rufus, after whom they were firſt named, *viz.* "pilula Rufi."

Pills *of Ammoniaret of Copper*, of the Edinb. Ph., conſiſt of ſixteen grains of ammoniaret of copper rubbed to fine powder, four ſcruples of crumb of bread, and a ſufficient quantity of water of carbonate of ammonia, beaten into a maſs, and divided into 32 equal pills. Theſe pills are given in epilepſy, and other ſpaſmodic diſeaſes: at firſt, one pill night and morning is ſufficient, but the number may be gradually increaſed till five be taken for a doſe.

Pills *of Gamboge, Compound*, are directed by the Lond. Ph. to be prepared by mixing together gamboge in powder, extract of ſpiked aloes in powder, compound powder of cinnamon, of each a dram, and then adding two drams of hard ſoap, and beating the whole together into an uniform maſs. This preparation is much more active than the aloetic pills; the doſe is from grs. x to ℈j, given at bed-time in obſtinate coſtiveneſs.

Pills *of Iron with Myrrh*, are compoſed, according to the Lond. Ph., of two drams of myrrh in powder, and ſubcarbonate of ſoda, ſulphate of iron, and ſugar, of each a dram: the myrrh is rubbed with the ſubcarbonate of ſoda, then, after having added the ſulphate of iron, rubbed again, and then the whole is beaten into a maſs. This is an uſeful emmenagogue pill; the doſe is from grs. x to ℈j, given twice or thrice a day.

Pills *of Galbanum, Compound*, of the Lond. Ph., conſiſt of galbanum, an ounce; myrrh and ſagapenum, of each an ounce and a half; aſſafœtida, half an ounce; and a ſufficient quantity of ſyrup; beaten together into an uniform maſs.

Pills, *Compound Aſſafœtida*, of the Edinb. Ph., are compoſed of aſſafœtida, galbanum, and myrrh, of each eight parts, and of purified oil of amber one part; beaten into a maſs, with ſimple ſyrup.

Pills *of Myrrh, Compound*, of the Dubl. Ph., conſiſt of aſſafœtida, myrrh in powder, and galbanum, of each an ounce, and of oil of amber half a dram; rubbed together, and made into a maſs with ſimple ſyrup.

Theſe preparations are uſeful antiſpaſmodics and emmenagogues, and are given with advantage in chloroſis, hyſteria, and hypochondriaſis. The doſe is from grs. x to ℈j, taken every night at bed-time.

Pills, *Mercurial, Pilulæ hydrargyri*, often from their colour called the *blue pills*, are prepared, according to the directions of the London and Dublin Pharmacopeias, by rubbing two drams of purified mercury with three drams of confection of red roſes, until the globules diſappear; then adding a dram of liquorice root in powder; and beating the whole into an uniform maſs. The Edinburgh Pharmacopeia directs them to be prepared by rubbing an ounce of purified mercury with the ſame quantity of the conſerve of red roſes, in a glaſs mortar, until the globules entirely diſappear, adding, if neceſſary, a little mucilage of gum arabic; then adding two ounces of ſtarch, and beating, with a little water, the whole into a maſs, which is to be directly divided into 180 pills of equal ſizes. N.B. One grain of mercury is contained in four grains of the maſs, prepared by the London and Dublin formulæ, and in three grains according to that of Edinburgh. Theſe pills are ſtimulant and antiſyphilitic, and are the moſt common form of preparation under which mercury is exhibited for the cure of venereal affections, as it is much leſs liable to act on the bowels than any of the other forms. The common doſe is from gr. vi to gr. viij, or two pills, given twice a day till the mouth be affected. Larger doſes are apt to excite purging.

Pills *of Submuriate of Mercury, Pilulæ hydrargyri ſubmuriatis*, of the London Pharmacopeia, are formed by rubbing a dram of ſubmuriate of mercury (calomel) with the ſame quantity of precipitated ſulphuret of antimony, then with two drams of guaiac gum-reſin, and adding a ſufficient quantity of copaiba to give the maſs a proper conſiſtence. This combination was firſt recommended by Dr. Plummer, in the Edinburgh Medical Eſſays, and diſtinguiſhed in the Edinburgh Pharmacopeia, by the name of "Plummer's Pill." From this pharmacopeia it was afterwards expunged; but as it was much uſed in practice, it has a place in the London Pharmacopeia. It is a very uſeful alterative in lepra, in ſecondary ſyphilis affecting the ſkin, and in other cutaneous diſeaſes. The doſe is from grs. v to grs. viij, given night and morning.

Pills, *Compound Rhubarb*, of the Edinburgh Pharmacopeia, are compoſed of one ounce of rhubarb root in powder, ſix drams of Socotorine aloes, half an ounce of myrrh, and half a dram of volatile oil of peppermint, beaten into a maſs with ſyrup of orange-peel. This is a warm, ſtomachic, laxative pill, very uſeful for obviating coſtiveneſs, and at the ſame time giving tone to the bowels in dyſpepſia and hypochondriaſis. The doſe is from grs. x to ℈j, given twice a day.

Pills *of Soap and Opium* are prepared, according to the London Pharmacopeia, by beating together half an ounce of hard opium powdered, and two ounces of hard ſoap, into an uniform maſs. Five grains contain one grain of opium.

Pills, *Opiate*, formerly called *Thebaic pills*, of the Edinburgh Pharmacopeia, conſiſt of one part of opium, ſeven parts of extract of liquorice, and two parts of pimenta berries; mixing the opium and extract, ſeparately ſoftened with diluted alcohol, and beating them into a pulp: then adding the Jamaica pepper rubbed to powder, and beating the whole into a maſs. Ten grains contain one grain of opium.

Pills, *Storax*, of the Dublin Pharmacopeia, are compoſed of three drams of purified ſtorax, and ſoft purified opium and ſaffron, of each a dram; mix them well together by beating. Five grains contain one grain of opium. Theſe preparations operate as an anodyne; but the doſe is different, and muſt be regulated by the qnantity of opium contained in that which is adopted.

Pills, *Compound Squill*, according to the London Pharmacopeia, are prepared by mixing together one dram of freſh ſquill-root (bulb) dried and powdered; ginger-root powdered, and hard ſoap, of each three drams, and two drams of ammoniacum powdered; and beating the mixed powders with the ſoap, adding as much ſyrup as will give them a proper conſiſtence.

Pills, *Squill*, of the Edinburgh Pharmacopeia, are prepared by beating one ſcruple of ſquill-root (bulb) dried and

and rubbed to a fine powder, ammoniacum, cardamom-feeds powdered, and extract of liquorice, one dram, with fyrup, into a mafs.

Pills *of Squill with Ginger*, of the Dublin Pharmacopeia, are compofed of a dram of powder of fquill, two drams of ginger-root in powder, and ten drops of effential oil of anifeed, beaten together and formed into a mafs with jelly of foap.

Thefe pills are ufeful expectorants in chronic catarrh, dyfpnœa, and afthma; and combined with calomel and digitalis in hydropic affections. As the efficacy of the fquill is much injured by keeping in either form, it is perhaps better that it fhould be always given under the extemporaneous form, except when the tincture is ufed. The dofe is from grs. x to ℈j, given three or four times a day. Thomfon's London Difpenfatory. London Pharmacopeia, 1809.

Pills, *Bechic*, a fort of pills good againft coughs, fo call from the Greek, *βηξ*, *cough*. They are alfo called *hypoglottides*, becaufe left like lozenges to diffolve under the tongue.

Pills *de Cochia*. See Cochia.

Pills *of Colocynth with Aloes*, *Pilulæ e colocynthide cum aloe*, a name given in the late London Pharmacopeia to the purging pill, commonly known by the name of *pilulæ cochiæ minores*.

As this is originally a prefcription of Galen, and the manner of proportioning the ingredients has been altered fince his time; the College have ordered it to be made in this manner: take of colocynth, pulp fliced, fix drams; extract of fpike aloe, powdered, one ounce and a half; fcammony gum-refin, powdered, half an ounce; cardamom-feeds, powdered, a dram; hard foap, three drams; and boiling water two pints. Macerate the colocynth pulp in the water for four days, in a gentle heat; ftrain the folution, and add to it the aloe, fcammony, and foap; then, by means of a water bath, evaporate it to a proper confiftence, conftantly ftirring, and about the end of the infpiffation, mix in the cardamom-feeds. This is the "extractum colocynthidis compofitum," P.L. 1787; "extractum catharticum," P.L. 1745; and "pilulæ Rudii," P.L. 1720. See Colocynthis.

Pilulæ e colocynthide fimpliciores, a name given in the late London Pharmacopeia to the purging-pill, commonly known by the name of *pil. ex duobus*. It is made of equal parts of colocynth and fcammony, with a confiderable proportion of oil of cloves; and is beat up to a confiftence with fyrup of buckthorn.

Pills, *Compofing*, are made by beating together ten grains of purified opium, and half a dram of Caftile foap; the whole may be formed into twenty pills: and one, two, or three, may be taken as occafion requires, when a quieting draught will not fit upon the ftomach.

Pills, *Fœtid*, are prepared by mixing half an ounce of affa foetida with any fimple fyrup. In hyfteric complaints, four or five pills of an ordinary fize may be taken twice or thrice a day. They will alfo be of fervice to perfons afflicted with the afthma; and they may be made opening, if neceffary, by adding a proper quantity of rhubarb, aloes, or jalap, to the above mafs.

Pills, *Hemlock*, are made by taking any quantity of the extract of hemlock, and adding to it about a fifth part its weight of the powder of the dried leaves, and forming it into pills. See Cicuta, in the *Materia Medica*.

Pills *for the Jaundice* are prepared by taking of Caftile foap, Socotorine aloes, and rhubarb, of each one dram, and making them into pills, with a fufficient quantity of fyrup or mucilage. See Jaundice.

Pills, *Mifaubin's*, a preparation of mercurius calcinatus (oxydum hydrargyri rubrum), fuppofed by Mr. Cavendifh (Phil. Tranf. vol. lxxiv. part i. p. 141.) to be the fame with red precipitate, though differently prepared: thefe pills being difpofed to occafion gripes, it has been ufual to add a fmall quantity of opium, and fome warm aromatic material. The dofe is from half a grain to two grains; five or fix grains are faid to vomit and purge violently.

Pills, *Perpetual*, or *Pilulæ perpetuæ*, are regulus of antimony made up in pills; thus called, becaufe being fwallowed and voided fifty times, they will purge every time with undiminifhed force. See Antimony.

Pills, *Plummer's*. See Plummer's *Æthiops*, and Pills *of Submuriate of Mercury*.

Pills, *Purging*. See Pills *of Aloes*, *Colocynth*, &c. fupra.

Purging pills may be made of Socotorine aloes and Caftile foap, of each two drams, and a fufficient quantity of fimple fyrup. Four or five of thefe will generally prove a fufficient purge. For keeping the body open, one may be taken night and morning. They are reckoned both deobftruent and ftomachic, and will be found to anfwer all the purpofes of Dr. Anderfon's pills, the principal ingredient of which is aloes. When aloetic purges are improper, let pills be formed of extract of jalap, and vitriolated tartar, of each two drams, and a fufficient quantity of fyrup of ginger; which may be taken as above.

Pill, *Rudius's*. See Extractum *Catharticum*, and Pills *of Colocynth*, &c. fupra.

Pills, *Soap*, *Pilulæ faponaceæ*, a form of medicine prefcribed in the late London Difpenfatory, and ordered to be made in the following manner: take almond foap, four ounces; ftrained opium, half an ounce; effence of lemons, a dram; foften the opium a little with wine, and beat that and the foap with the effence, till it be reduced to the form of a pill. See Opium, and Pills *of Soap*, &c. fupra.

This is intended to fupply the place of a pill commonly called *Matthew's* pill, and is very happily corrected in regard to the tafte of the foap, by the addition of the effence of lemons.

Pills, *Stomachic*, are made of extract of gentian, two drams; powdered rhubarb and vitriolated tartar, of each one dram; oil of mint, thirty drops: and a fufficient quantity of fimple fyrup. Three or four of thefe may be taken twice a day, for invigorating the ftomach, and keeping the body gently open.

Pills, *Strengthening*, are made of foft extract of the bark, and falt of fteel, of each half an ounce. In diforders arifing from exceffive debility or relaxation of the folids, as the chlorofis, or green ficknefs, two of thefe pills may be taken three times a day.

Pill, *Ward's*. See Ward's *Pill*.

PILLAGE, among *Builders*, is fometimes ufed for a fquare pillar, ftanding behind a column to bear up the arches; having a round bafe and capital, as a pillar has.

Pillage *Bay*, in *Geography*, a bay on the S. coaft of Labrador. N. lat. 50° 17′. W. long. 62° 58′.

PILLAR, in *Architecture*, a kind of irregular column, round and infulate; but deviating from the proportions of a juft column.

Pillars are always either too maffive, or too flender, for a regular architecture. In effect, pillars are not reftrained to any rules: their parts and proportions are arbitrary. Such, *e. gr.* are the pillars which fupport Saracenic vaults, and other buildings, &c.

A fquare pillar is a maffive work, called alfo pier, or piedroit,

piedroit, serving to support arches, &c. See Pier, and Piedroit.

Butting-pillar is a butment, or body of masonry, raised to prop, or sustain, the thrust of a vault, arch, or other work. See Buttress.

It seems not impossible for stone to be cast into the shape of pillars. We find mention made in the Philosophical Transactions, of two pillars of stone at Fontevraud, in France, each about sixty feet high, all of one solid piece, which are said to have been run. (N° 481. p. 328. in Not.) Pillars of stone were anciently erected, as sepulchral monuments, near the highways; and also in memory of some victory. We find traces of this custom in Cornwall and Wales, where these pillars are often found, and called *meinigwir*, a stone for play, perhaps in memory of funeral games; and sometimes *llech*, that is, *tabula saxea*. Phil. Trans. N° 458. p. 471.

Pompey's pillar is a famous monument of antiquity, constructed of red granite, and situated on a rock, about a mile without the walls of Alexandria, in Egypt. By the mensuration of Edward Wortley Montagu, esq. the capital of the pillar, which is Corinthian, with palm leaves, and not indented, is nine feet seven inches high; the shaft sixty-six feet one and a quarter inch; the base five feet nine three quarter inches; the pedestal ten feet five and a half inches; the height from the ground ninety-two feet: though Dr. Pococke, by the shadow, determined the whole height to be one hundred and fourteen feet; and its diameter nine feet and an inch. It is perfectly well polished, and only a little shivered on the eastern side. Nothing can equal the majesty of this monument: seen from a distance, it over-tops the town, and serves as a signal for vessels. Approaching it near, it produces, says Savary, an astonishment mixed with awe. One can never be tired with admiring the beauty of the capital, the length of the shaft, nor the extraordinary simplicity of the pedestal. This prodigious mass stands, as on a pivot, on a reversed obelisk; and was erected, as many have supposed, either by Pompey, or to his honour. But as no mention is made of it by Strabo, Diodorus Siculus, or any other ancient writers, Mr. Montagu concludes that it was not known before the time of Vespasian, and that it was erected to his honour. In proof of this opinion, he found within the circumference of the pillar a medal of Vespasian in fine order.

Savary, on the authority of Abulfeda, who calls it "the pillar of Severus," ascribes it to this emperor; alleging that he visited Egypt, gave a senate to Alexandria, and deserved well of its inhabitants. Accordingly, it is said, that this column was a mark of their gratitude. The Greek inscription, half effaced, which is visible on the west side when the sun shines upon it, was legible, without doubt, in the time of Abulfeda, and preserved the name of Severus. Nor is this the only monument erected to him by the gratitude of the Alexandrians. In the midst of the ruins of Antinoe built by Adrian, is seen a magnificent pillar, the inscription on which is still remaining, dedicated to Alexander Severus.

Denon has given a drawing of this pillar, with the marked dimensions of its various parts: he makes its whole height a fraction more than 92 feet, and the height of the shaft, which is of a single piece, 63 feet 1.3. It acquired, as this author says, the name of Pompey's pillar in the 15th century. A monument, as he supposes, had been raised by Pompey at Alexandria, but it had disappeared, and was thought to be recovered in this pillar or column, which has since been converted into a trophy erected to the memory of Septimius Severus. It is, however, placed on the ruins of the ancient city; and in the time of Septimius Severus, the city of the Ptolemies was not in a ruinous state. To support this column by a solid foundation, an obelisk has been sunk in the earth, on which is placed a very clumsy pedestal, having a fine shaft, and surmounted by a Corinthian capital of bad workmanship. If the shaft of this column, continues Denon, separating it from the pedestal and the capital, once belonged to an ancient edifice, it is an evidence of its magnificence, and of the skill with which it was executed. It ought, therefore, to be said, that what is called Pompey's pillar is a fine column, and not a fine monument; and that a column is not a monument. The earth about the foundation of this pillar having been cleared away by time, two fragments of an obelisk, of white marble, the only monument of that substance seen by Denon in Egypt, have been added to the original base, to render it more solid. After having observed that the column, entitled Pompey's pillar, is very chaste both in style and execution; that the pedestal and capital are not formed of the same granite as the shaft; that their workmanship is heavy, and appears to be merely a rough draft; and that the foundations, made up of fragments, indicate a modern construction; it may be concluded, says our author, that this monument is not antique; and that it may have been erected either in the time of the Greek emperors, or of the caliphs; since, if the capital and pedestal are well enough wrought to belong to the former of these periods, they are not so perfect but that art may have reached so far in the latter. See Pococke's Descr. of the East, vol. i. p. 8. and Phil. Trans. vol. lvii. art. 42. Savary's Letters in Egypt, vol. i. Denon's Travels in Egypt, vol. i.

Pillar, in the *Manege*, signifies the centre of the volta, ring, or manege ground, round which a horse turns, whether there be a wooden pillar in it or not.

There are also pillars in maneges on the circumference, or side, placed at certain distances, by two and two. To distinguish these from that of the centre, they are called the *two pillars*. When these latter are spoken of, it is usual to say, *Work the horse between the two pillars*. When the former, it is called, *Working round the pillar*. The use of the pillar in the centre is for regulating the extent of the ground, that the manege upon the volts may be performed with method and justness, and that they may work in a square, by rule and measure, upon the four lines of the volts; and also to break unruly high-mettled horses, without endangering the rider.

The two pillars are placed at the distance of two or three paces one from the other. The horse is put between these, to teach him to rise before, and yerk out behind, and put himself upon raised airs, &c. either by the aids, or chastisement.

It has been supposed, that the hint of using pillars in the manege was taken from a contrivance of Eumenes; who, as Plutarch relates it, being besieged at the fort of Nora, by Antigonus, and fearing lest his horses should suffer for want of action, contrived a method of working them, without removing them from their stalls. For this purpose he placed a pulley over their heads in the beams of the stables, with which, by means of running reins, he pulled up their fore-parts, causing at the same time people to stand behind them, who, urging and lashing them with whips, put them into motion, made them yerk out behind, raising and moving their fore-legs, and work and chase themselves till they sweat copiously; by these means he preserved their health, kept them in wind, and ready for service. The single pillar, once so frequent in maneges, but now laid aside, was first used in Naples, and owes its origin to the want of covered buildings for riding and breaking horses: in lieu of which they

they dug trenches for working their horfes; the fides of the trenches fupplying the want of walls, and producing in a certain degree the fame effect. The famous Pignatelli, of Naples, having no covered manege, worked his horfes in the open air, and ufed to tie them to a tree, and work them round it. Pluvinal, of France, was one of his fcholars; and returning to France, where he profeffed horfemanfhip, he placed a poft or pillar in his manege, in imitation of Pignatelli's tree, and made the fame ufe of it: to this he foon added another of the fame fize and height; which two pillars were calculated to anfwer purpofes different from thofe for which the fingle pillar had been erected: the two pillars are ftill in ufe, and reckoned an effential piece of furniture in all riding-houfes. The fingle pillar has been long difcontinued, but may be employed to advantage upon certain occafions; efpecially where a horfeman undertakes to *longe* a horfe, without the affiftance of another perfon. It fhould be obferved that no horfe ought to be put between the two pillars till he is well fupplied, and has acquired the firft principles of the union between the legs, which are the natural pillars that every horfeman fhould employ. The horfe fhould be gently worked at firft, that he may not become furious, and he fhould be made to go only from fide to fide by means of the fwitch, or from fear of the chambriere. In a few days, when he is accuftomed to the fubjection of the pillars, try to make him infenfibly go into the cords, and endeavour to get from him a ftep or two exact, and in time of the *paffage* or *piaffer*.

The worft effect of the pillars is the hazard you run of entirely ruining the hocks of your horfe, if you do not diftinguifh very exactly between thefe parts and the haunches. Berenger's Hift. and Art. of Horfemanfhip, vol. ii. p. 60. and 164, &c.

Pillar, *Cape*, in *Geography*, a cape at the weftern entrance of the ftraits of Magellan, which is known by a large gap upon the top; and when it bears W.S.W. an ifland appears off it which has an appearance fomewhat like a hay-ftack, and about which lie feveral rocks. The ftrait to the eaftward of the cape is between feven and eight leagues over; the land on each fide is of a moderate height, but it is loweft on the north fhore, the fouth fhore being much the boldeft, though both are craggy and broken. Weftminfter ifland is nearer to the north than the fouth fhore; and by the compafs lies N.E. from cape Pillar. S. lat. 52° 45'. W. long. 75° 10'.

Pillars, in *Ship Building*, are fquare or round columns of timber, fixed perpendicularly under the middle of the beams for the fupport of the decks.

Pillars, *Ropes of two*. See Rope.

PILLAU, in *Geography*, a fea-port town of Pruffia, in the province of Samland, fituated on a tongue of land that projects into the Baltic, at the entrance of the Frifch Haff, with a good harbour; well fortified, and confidered as the bulwark and key of the kingdom. The ftreets are broad and ftraight; and the houfes are built and furnifhed in the Dutch tafte. This harbour is frequented by foreign fhips, and the town is the refort of people of various nations. The fort is nearly a regular pentagon; the baftions exhibit a grand appearance; and all the edifices belonging to the fortifications are ftrong, handfome, and regular. Here is alfo a magazine for military ftores. In the fort there is a church, ferving for both the Lutherans and Calvinifts, and below the gate of the caftle is a ftone equeftrian ftatue of Frederic William the Great. Over the gate, on one fide of the entrance, ftands the image of Mars, in a bold attitude, looking towards Sweden. The peninfula along which the road from Pillau to Fifchhaufen lies, is called the "Paradife of Pruffia," from its pleafantnefs and fertility. Near the fort is a fine plain, where the Frifch Haff forms a fine femicircular bay, that is frequented by a great number of fwans, fea-mews, wild-ducks, and other water-fowl. On the other fide of the bay lies Alt Pillau or Old Pillau, inhabited by fifhermen; 22 miles W.S.W. of Königfberg. N. lat. 54° 37'. E. long. 19° 55'.

PILLE *of Foddray*, or Pile *Fouldery*, in the county of Lancafter; a defence built on a creek of the fea, called *Pille*, by the idiom of the county, for a pile, or a fort, built for the fafeguard or protection of any place.

This pile was erected there by the abbot of Fourneffe, in the firft year of Edward III. Camd. Brit. Rex. "Dedimus Henrico comiti Northum. infulam, caftrum, pelam, & dominium de Man, &c." Rot. Par. 1 Hen. IV.

PILLEER, in *Geography*, a town of Hindooftan, in Myfore; nine miles N.W. of Dalmachery.

PILLERSTORFF, a town of Auftria, on the river Rufbach; eight miles E.N.E. of Korn-Neuberg.

PILLIBEAT, a town of Hindooftan, in Rohilcund; 28 miles N.E. of Bereilly. N. lat. 28° 36'. E. long. 80° 10'.

PILLORY was anciently a poft erected in a crofs road, by the lord, as a mark of his feigniory, with his arms on it, and fometimes with a collar to tie criminals to.

Pillory, at prefent, is a wooden machine, on which certain criminals, as perjurers, &c. are faftened, and expofed to the public derifion.

With us it is in the form of a frame erected on a pillar, and made with holes and folding boards, through which the heads and hands of criminals are put.

The etymology of this word has been varioufly affigned by different writers: Spelman derives it from the French *pilleur*, *depeculator*; Cowel from πυλη, *janua*, and οραω, *video*; but the etymology of Du-Cange is the moft probable, who derives it from *pila*, *a pillar*.

In the laws of Canutus it is called *healfchang*. Sir Henry Spelman fays it is *fupplicii machina ad ludibrium, magis quam pœnam*. It was peculiarly intended for the punifhment of bakers who fhould be caught faulty in the weight, or finenefs, of their bread. In old charters it is called *colliftrigium*.

The pillory in Paris is in the middle of a round tower, with openings on every fide. It is moveable on an axis, or arbor; round which the executioner gives the criminal the number of turns appointed in court; ftopping him at each opening, to fhew him to the people. It was intended for feveral kinds of criminals, particularly for fraudulent bankrupts; and all thofe who made a ceffion, or furrender, of their effects to their creditors, were obliged to take fome turns round the pillory on foot, with a green cap on.

PILLOW *of a Plough*, a term ufed by the farmers to exprefs that part of a plough which ferves to raife or fink the beam, and with it the fhare, as the land is to be ploughed fhallower or deeper.

This pillow is a crofs piece of wood, reaching from one of the crow-ftaves, or uprights, to the other; and as they are bored with two rows of holes, this pillow can be flipped up or down to any height, and kept there by pegs or cords in the holes. See Plough.

Pillow, in a *Ship*, is that piece of timber whereon the bowfprit refts at its coming out of the hull aloft, clofe by the ftem.

PILLVENKEGEN, in *Ornithology*, the name of a bird approaching to the fnipe kind; defcribed by Aldrovand, and fuppofed by fome to be the bird we call the *knot*.

PILNAUD, in *Geography*. See Palnaud.

PILNIKAW, a town of Bohemia, in the circle of Koningingratz; five miles W.S.W. of Trautenau.

PILNITZ, a town of Saxony, in the margraviate of Meissen, seated on the Elbe, in which is a royal palace; celebrated for a treaty entered into by the powers of Europe against France in 1792; seven miles S.E. of Dresden.

PILOBOLUS, in *Botany*, from πιλος, *a cap* or *cover*, and βολος, *a throw*, or *cast*. Tode Fung. Mecklenb. fasc. 1. 41. Perf. Syn. 117.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Receptacle stalk-like, pellucid, bearing a naked vesicle, which flies off elastically.

1. P. *crystallinus*. Perf. Obf. Mycolog. v. 1. 76—78. t. 4. f. 9—11. Fl. Dan. t. 1080. (Mucor urceolatus; Dicks. Crypt. fasc. 1. 25. t. 3. f. 6. Bull. Fung. t. 480. f. 1.)—Receptacle obovate. Vesicle hemispherical, black. —Common in autumn on horse or cow-dung. In an early state it appears, according to the observations of Persoon, like some little yellowish kind of *Sphæria*; but it soon becomes an obovate, stalked, pellucid, whitish body, about half an inch high, full of a clear watery liquor, and bearing on its top a black hemispherical head, of short duration.

2. P. *roridus*. Perf. n. 2. (Mucor roridus; Bolt. Fung. t. 132. f. 4. Relh. Cant. 548?)—Receptacle globose, with a capillary stalk. Vesicle depressed, black.—Found by Bolton on horse-dung, in fields about Halifax, in August and September, when the morning is cloudy, as it perishes when the sun shines upon it. The plants are four lines high, growing in clusters, and distinguished from the former by the long slender *stalk*, globose *head*, and minute, depressed, black *vesicle*.

PILOCARPUS, from πιλος, *a cover*, and καρπος, *fruit*. Vahl Eclog. v. 1. 29. Willd. Sp. Pl. v. 1. 1133. Mart. Mill. Dict. v. 3.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Dumosæ*, Linn. *Rhamni*, Juss.

Eff. Ch. Calyx of five leaves. Petals five. Stamens inserted under the germen. Capsules five, combined at the base, elastic. Seeds solitary, tunicated.

1. P. *racemosus*. Vahl t. 10. (Euonymus latifolius racemosus, fructu pentagono atropurpureo; Plum. Ic. 119. t. 127.)—Native of lofty mountains in the island of Montserrat. A low *shrub*, with pendulous branches. *Leaves* alternate, on short stalks, elliptical, entire, very obtuse, and generally emarginate. *Clusters* terminal, solitary, many-flowered, a foot or more in length. We readily agree with Willdenow that this plant is very nearly akin to *Euonymus*; certainly far more so than to *Prunus*, to which Burmann, the editor of Plumier, refers it!

PILORUS, in *Ancient Geography*, a town of Macedonia, situated at the foot of mount Athos, or rather on the Singitic gulf, S.W. of Asia.

PILOSE LEAF, in *Botany*. See LEAF.

PILOSELLA, diminutive of *pilosa*, hairy, an old appellation, and now the Linnæan specific name, of a very common species of *Hieracium*, remarkable for the long tawny hairs of its leaves.

PILOT, the person who superintends the navigation of a ship, either upon the sea-coast, or on the main ocean; but it is more particularly applied to a person retained on board a ship to conduct it into a road or harbour, or over bars or sands; or through serpentine and intricate channels, or the like.

Menage derives the word pilot from *prorita*; *q. d.* he who governs the prow, or head. Others fetch it from the old French *pile*, *a ship*.

Pilots are no constant and standing officers on board our vessels; but are mostly called in occasionally, on coasts and shores unknown to the master. And, having done their parts in piloting the vessel, they return to shore, where they reside.

The regulations, with regard to pilots in the royal navy, are as follow: the commanders of the king's ships, in order to give all reasonable encouragement to so useful a body of men as pilots, and to remove all their objections to his majesty's service, are strictly charged to treat them with good usage, and in equal respect with warrant-officers.

The purser of the ship is always to have a set of bedding provided on board for the pilots, and the captain is to order the boatswain to supply them with hammocks, and a convenient place to lie in, near their duty, and apart from the common men; which bedding and hammocks are to be returned when the pilots leave the ship.

A pilot, when conducting one of his majesty's ships in pilot-water, shall have the sole charge and command of the ship, and may give orders for steering; setting, trimming, or furling the sails; tacking the ship; or whatever concerns the navigation: and the captain is to take care that all the officers and crew obey his orders. But the captain is diligently to observe the conduct of the pilot, and if he judges him to behave so ill as to bring the ship into danger, he may remove him from the command and charge of the ship, and take such methods for her preservation as shall be judged necessary; remarking upon the log-book the exact hour and time when the pilot was removed from his office, and the reasons assigned for it.

Captains of the king's ships, employing pilots in foreign parts of his majesty's dominions, shall, after performance of the service, give a certificate thereof to the pilot, which being produced to the proper naval officer, he shall cause the same to be immediately paid; but if there be no naval officer there, the captain of his majesty's ship shall pay him, and send the proper vouchers, with his bill, to the navy-board, in order to be paid as bills of exchange.

Captains of his majesty's ships, employing foreign pilots, to carry the ships they command into or out of foreign ports, shall pay them the rates due by the establishment or custom of the country, before they discharge them; whose receipts being duly vouched, and sent with a certificate of the service performed, to the navy-board, they shall cause them to be paid with the same exactness as they do bills of exchange. Regulations and Instructions of the Sea Service, &c.

Pilots of ships taking upon them to conduct any ship from Dover, &c. to any place up the river Thames, are to be first examined and proved by the master and wardens of the Trinity-house, &c. or shall forfeit 10*l.* for the first offence, 20*l.* for the second, and 40*l.* for every other offence; one moiety to the informer, the other to the master and wardens; but any master or mate of a ship may pilot his own vessel up the river: and if any ship be lost through the negligence of any pilot, he shall be for ever afterwards disabled to act as a pilot. (3 Geo. I. cap. 13.) The lord wardens of the cinque-ports may also make rules for the government of pilots, and order a sufficient number to ply at sea to conduct ships up the Thames. 7 Geo. I. cap. 21.

No person shall act as a pilot on the Thames, &c. (except in collier ships) without licence from the master and wardens of the Trinity-house, at Deptford, on pain of forfeiting 20*l.* Pilots are to be subject to the government of that corporation, and pay ancient dues not exceeding 1*s.* in the pound out of wages for the use of the poor thereof. (5 Geo. II. cap. 20.) In charter parties of affreightment, the master generally covenants to find a pilot, and the merchant to pay him; and in case the ship shall miscarry through the

the infufficiency of the pilot, the merchant may charge either the mafter or the pilot; and if he charges the mafter, fuch mafter muft have his remedy againft the pilot. Lex Mercator. 70.

Among the French, pilot is alfo ufed for a fteerfman, or an officer on board a fhip, who always watches her courfe, and directs it.

There are among the French two kinds of pilots; the one a coafting pilot, well acquainted with the coafts, ports, roads, bars, fands, &c., and who commands in fight thereof. The other an officer who makes obfervations, and takes altitudes out at fea; ufes the quadrant and fore-ftaff; and alfo watches the compafs.

The pilot is always the fecond perfon in the fhip, whether it be a man of war, or merchant-man. In the former the captain is the firft, the pilot the fecond. In a merchant-fhip, the mafter is the firft, the pilot after him.

The pilot is alfo the fteerfman, who ftands at the helm, and manages the rudder.

PILOTAGE, money paid for piloting a fhip.

PILOTING, in *Navigation*, is either common or proper: common piloting is that art which confifts in coafting along fhore, or failing within fight of land. Proper piloting is the art of failing to diftant places through the ocean, and out of fight of land. See NAVIGATION, PILOT, and SAILING.

PILOTO, or *Salinas del Piloto*, in *Geography*, craggy rocks on the W. coaft of Mexico, S.E. of Cape Corientes, where are good anchorage, and fhelter from N.W. and W. and S.W. winds, and near which are falt-pits.

PILOT-TOWN, a town of America, in Suffex county, Delaware; fix miles N.W. of Cape Healopen.

PILOUTA, a town of Candahar, on the Attock; 90 miles N.N.W. of Moultan.

PILOUTAI HOTUN, a town of Chinefe Tartary, near the river Hoang-ho; 300 miles W. of Peking. N. lat. 40° 38′. E. long. 108° 43′.

PILPAY, or BIDPAY, in *Biography*, an oriental philofopher, of whofe country, time, life, or works, little is known with any degree of certainty. According to tradition he was the counfellor and vizier to an ancient king of India, for whofe ufe he compofed his famous apologues or fables. Thefe apologues are in the form of dialogues between two animals of a fpecies very like the European fox. The fame of this work having reached Perfia, Chofroes, the king of that country, is faid to have fent his phyfician into India for the fole purpofe of procuring a copy of it. This phyfician, being permitted to perufe it in the library of the Indian king, tranflated it into the ancient Perfian, and gave it the title of the *royal or auguft book.* Such is the account given of Pilpay, and of the introduction of his fables into Perfia. The work itfelf is thought to contain internal evidence of its having been written at a much later period. It has been tranflated into moft of the modern languages; but the beft European verfion is the French one of M. Galland, publifhed in two vols. 12mo. 1714, with relics of the fables of Lokman. The fame writer publifhed the tranflation of another work attributed to Pilpay, entitled "The Shipwreck of the floating Iflands, or the Bafiliad." Enfield's Hift. Phil.

PILSEN, in *Geography*, a town of Hungary, on the river Ipol; 10 miles N.E. of Gran.—Alfo, a well-built and fortified town of Bohemia, and capital of a circle of the fame name, fituated near the conflux of the rivers Miza and Radbuzo. The circle is rich in fheep; and the cheefe made by the inhabitants is preferred to any other in the kingdom; 44 miles S.W. of Prague. N. lat. 49° 43′. E. long. 13° 33′.

PILSENITZ, a town of Bohemia, in the circle of Pilfen; five miles S.E. of Pilfen.

PILSNO, a town of Auftrian Poland; 56 miles S.W. of Sandomirz.

PILSTART. See PYLSTART.

PILSTING, a town of Bavaria; two miles N. of Landau.

PILTEN, a town of the duchy of Courland, and capital of a diftrict, anciently called "the diocefe of Courland;" 12 miles N.N.W. of Goldingen. N. lat. 57° 5′. E. long. 21° 38′.

PILTEN *Lake*, a lake of Chinefe Tartary, 23 miles in circumference; 25 miles S.W. of Nimgouta.

PILULARIA, in *Botany*, from *pilula*, a little ball, or pill, in allufion to the fhape of its receptacles.—Linn. Gen. 561. Schreb. 754. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1143. Juff. 16. Lamarck Illuftr. t. 862.—Clafs and order, *Cryptogamia Filices*, or perhaps *Monoecia Polyandria.* Nat. Ord. *Filices*, Linn. Juff.

Eff. Ch. Common receptacle globofe, of four cells and four valves, filled with numerous anthers in the upper part, and numerous piftils in the lower. Seeds coated.

1. P. *globulifera*. Pillwort. Linn. Sp. Pl. 1563. Engl. Bot. t. 521. Bolt. Fil. 72. t. 40. Fl. Dan. t. 223. Bulliard t. 375. (P. paluftris juncifolia; Vaill. Par. t. 15. f. 6. Dill. Mufc. 538. t. 79. Pepper-grafs; Pet. Herb. Brit. t. 9. f. 8.)—This, the only known fpecies of its genus, is found on heaths that are partially inundated, in various parts of England, France, and Germany, flowering in June and July. The thread-like *ftem* creeps clofe to the ground, with fibrous *roots* fuppofed to be perennial, and throws up many erect, fcattered or clustered, awl-fhaped, fmooth, fimple branches, two or three inches high, each of which unrolls, in the peculiar manner of genuine ferns, or of fome intermediate plants between ferns and palms, as the *Cycas* and *Zamia*, to which, however widely different in dimenfions, the *Pilularia* is perhaps moft allied. Its little blackifh globular *fruits*, or *receptacles*, refembling pepper-corns, are folitary, and nearly feffile, at the bafes of the branches, and are externally downy. Bulliard's figure is excellent.

PILUM, in *Roman Antiquity*, a maffive weapon, which in charge they darted upon the enemy. It was commonly four-fquare, but fometimes round, compofed of a piece of wood three cubits long, and a flip of iron of the fame length, hooked and jagged at the end.

PILWARA, in *Geography*, a town of Hindooftan, in Oudipour; 40 miles N. of Oudipour. N. lat. 25° 19′. E. long. 74° 25′.

PILY BARRY. See BARRY *Pily*.

PILZICHE, in *Geography*, a town of Saxony, in the circle of Erzgebirg; 10 miles S.E. of Schwarzenberg.

PIMBLE-MERE. See BALA POOL.

PIMELA, in *Botany*, from πιμελη, *fatnefs*, becaufe of the oily nature of its nut, a genus of Loureiro's, Cochinch. 407. See CANARIUM.

PIMELÆA, a name adopted, by the writer of this, from the manufcripts of the celebrated Solander, and derived from πιμελη, *fatnefs;* in allufion, as it is fuppofed, to the oilinefs of its little oval feed, like an olive in miniature. As there is a Fabrician genus of infects named *Pimelia*, from their corpulent fhape, we wifh to include the idea of an olive, ελαια, in the above word; writing it therefore with a diphthong, to guard againft ambiguity, either in its fenfe or pronunciation.—Sm. Bot. of New Holl. 31. Mart. Mill. Dict. v. 3. Willd. Sp. Pl. v. 1. 50. Vahl. Enum. v. 1.

v. 1: 305. Brown Prodr. Nov. Holl. v. 1. 359. Ait. Hort. Kew. v. 1. 25. Lamarck Illuftr. t. 9. (Bankfia; Forft. Gen. t. 4.)—Clafs and order, *Diandria Monogynia.* Nat. Ord. *Veprecula*, Linn. *Thymelææ*, Juff. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, funnel-fhaped, coloured; tube thread-fhaped, very long; limb fpreading, in four deep fegments, two oppofite ones exterior; mouth naked and pervious. *Cor.* none. *Stam.* Filaments two, capillary, inferted into the mouth of the tube, oppofite to the outer fegments (*Brown*); anthers roundifh, erect, fimple, of two cells. *Pift.* Germen ovate, fuperior; ftyle thread-fhaped, as long as the tube, inferted laterally into the germen; ftyle capitate, fmall, fmooth. *Peric.* a dry, or flightly fucculent, berry, with a thin coat. *Seed* folitary, ovate, obliquely pointed.

Eff. Ch. Calyx funnel-fhaped, four-cleft, coloured, withering. Petals none. Stamens prominent, inferted into the top of the tube. Style lateral. Stigma capitate, fmooth. Seed coated.

Obf. This genus comes neareft in technical characters to *Pafferina*, from which it differs neverthelefs fufficiently, in having but two ftamens inftead of eight, and, if we miftake not, a conftantly fmooth ftigma, inftead of a hifpid one. (See PASSERINA, GNIDIA, and DAPHNE, for remarks on the generic characters of this tribe.) Forfter originally called the genus before us *Bankfia*; but its fpecies having all been reduced, by Linnæus and his fon, to *Pafferina*, a much finer genus was fortunately chofen to commemorate our illuftrious countryman, and the name which he and his friend Dr. Solander had firft contrived for this, is now retained. Of its numerous fpecies we know not how to give any thing more than a comprehenfive idea, nor can we calculate their number with perfect precifion. Willdenow has only four, confifting of our *linifolia*, firft publifhed in the Botany of New Holland, and the three Forfterian *Bankfiæ*, given as *Pafferinæ* in Linn. Suppl. 226, 227. Vahl has added two. Labillardiere defcribes fix more, from the fouth coaft of New Holland. But Mr. Brown has carried our knowledge of this genus far beyond any preceding writer, as he defines thirty-four fpecies of *Pimelæa* from New Holland alone. In thefe are not included the above three plants of Forfter, nor the *virgata* of Vahl, being natives of New Zeeland only; from which country we are poffeffed of three others, given by fir Jofeph Banks to the younger Linnæus, and hitherto, we believe, entirely nondefcript. Thus the known fpecies may be reckoned to amount to forty-one. Of thefe *linifolia* alone is mentioned in the Hortus Kewenfis, as cultivated in Britain. Mr. Brown divides this genus into five fections, of which we fhall give examples.

Sect. 1. *Leaves oppofite. Flowers in a terminal head. Involucrum (or rather four bracteas) unlike the leaves.* Fourteen fpecies.

P. *cornucopiæ.* Vahl. n. 1. Br. n. 1.—Common bractea of one leaf, funnel-fhaped, with four broad acute fegments. Stem herbaceous.—Gathered by fir Jofeph Banks at New South Wales, in 1770. Mr. Brown has met with the fame in the tropical part of New Holland. This is one of the very few herbaceous fpecies, moft of the genus being fhrubby, with the habit of *Daphne* and *Pafferina.* Every part is fmooth. *Branches* flender. *Leaves* an inch long, more or lefs, elliptic-lanceolate, entire as in all the reft of this natural order, of a fine green, minutely dotted. *Flowers* fmall, greenifh-yellow, with a reddifh flender tube about half an inch long. *Stamens* about the length of the rather unequal limb. The head of *flowers* is encompaffed with four broad, acute, green *bracteas*, about its own length, the two outermoft heart-fhaped at the bottom, and all connected by an inverfely conical bafis, of one leaf, refembling a *cornucopia.*

P. *linifolia.* Flax-leaved Pimelæa. Sm. Bot. of New Holl. 31. t. 11. Willd. n. 1. Br. n. 4. Vahl n. 2. Curt. Mag. t. 891.—Bracteas ovate, broad, fmooth on both fides, half the length of the head. Tube of the calyx filky. Leaves linear-lanceolate, or partly fpatulate, ftalked, fingle-ribbed.—Native of New South Wales and the ifland of Van Diemen. *Br.* In England it is a green-houfe fhrub, bearing, from February to Auguft, a profufion of elegant, white, but inodorous, *flowers.* The copious ftraight *branches* are clothed with numerous, fmooth *leaves*, about an inch long, variable in breadth. The globular briftly common *receptacle* remains long after the *flowers* and *feeds* are fallen, furmounted by numerous young flowering branches.

Sect. 2. *Leaves oppofite. Head terminal. Bracteas fcarcely different from the leaves.* Fifteen fpecies in Mr. Brown's Prodromus; to which are to be added the New Zeeland fpecies, all of them, as far as we have feen, anfwering to the character of this fection.

P. *drupacea.* Labill. Nov. Holl. v. 1. 10. t. 7. Br. n. 27.—Leaves oval-oblong, flat, flightly downy beneath; floral ones longer than the head. Tube of the calyx cylindrical, deciduous. Fruit pulpy.—From Van Diemen's land. Above fix feet high. Young *branches* hairy. *Leaves* about an inch and a half long; the floral ones two or four, fometimes larger, fometimes fmaller, than the reft. Befides the ufual terminal head of *flowers*, there are feveral fmall, oppofite, axillary ones, with two diminutive floral leaves to each. *Stamens* half the length of the limb. *Berry* black, pulpy.

P. *longifolia.* Banks, Herb. Linn. fil.—Leaves lanceolate, acute, fmooth on both fides; floral ones twice as long as the many-flowered head. Calyx externally filky.—Gathered by fir J. Banks at New Zeeland, in 1769. This feems to be a tall and handfome *fhrub*, fmooth in every part except the *flowers*, which are white, externally filky, with elliptical obtufe fegments. *Leaves* willow-like, three inches long, half an inch wide, on fhort broad *footftalks*; the floral ones four, half the fize of the reft, but full twice the length of the flowers.

P. *lævigata.* (P. lævigata β; ibid.)—Leaves ovate, obtufe, concave, fmooth on both fides; floral ones the length of the head. Calyx and young branches filky.—From the fame country. *Stem* apparently procumbent. Young *branches* numerous, clothed with fine, denfe, rather prominent, white, filky hairs. *Leaves* fcarcely above a quarter of an inch long, perfectly fmooth and naked; the floral ones exactly like the reft. *Flowers* many in each head, the length of the leaves, externally finely filky; their fegments broad and rounded.

P. *villofa.* Ibid.—Leaves imbricated, ovate, acute, concave; fmooth above; very hairy beneath; floral ones the length of the head. Calyx and young branches hairy.—From the fame country. This agrees with the laft in fize, but feems more erect, and differs in the long fhaggy, though fhining, pubefcence of the *flowers*, young *branches*, and backs of the *leaves*.

P. *proftrata.* Vahl n. 6. (P. lævigata α; Banks, H. Linn. fil. Bankfia proftrata; Forft. Gen. t. 4. f. *k*—*n*. Pafferina proftrata; Linn. Suppl. 227. Forft. Prodr. 28.)—Leaves elliptical, obtufe, concave, fmooth on both fides; floral ones the length of the head. Calyx and young branches hairy.—Native of dry hills in New Zeeland. Very like the laft but one, though fmaller in all its parts, with elliptical

elliptical rather than ovate *leaves*, fewer *flowers* in each head, and flightly hairy, rather than denfely filky, young *branches*, as well as *calyx*. It is ftill poffible this and *lævigata* may be varieties of each other, as their original difcoverers thought.

P. *pilofa*. Vahl. n. 4. (Bankfia tomentofa; Forft. Gen. n. 2. Pafferina pilofa; Linn. Suppl. 226. Forft. Prodr. 28.)—Leaves lanceolate, obtufe, hairy beneath; floral ones rather ovate, twice the length of the few, lateral or terminal, hairy flowers.—Found in New Zeeland.—*Stem* erect, woody. *Branches* repeatedly forked, fhort, fpreading, filky. *Leaves* about an inch long; lofing their hairs by age.

P. *Gnidia*. Vahl n. 3. (Bankfia Gnidia; Forft. Gen. t. 4. f. *a—i*. Pafferina Gnidia; Linn. Suppl. 226. Forft. Prodr. 28.)—Leaves ovato-lanceolate, acute, ftalked, rigid, channelled, quite fmooth, as well as the branches. Calyx very hairy.—Found in the fiffures of rocks in New Zeeland, near the coaft, as well as on the loftieft mountains. The copious bright-green *leaves*, about an inch long, have the afpect of myrtle. The floral ones rather exceed in length the denfe heads of copious white *flowers*, whofe outfide is very hairy.

Sect. 3. *Leaves oppofite. Flowers fpiked.* One fpecies only.

P. *fpicata*. Br. n. 30.—Leaves oval, fmooth, as well as the calyx. Spikes naked. Flowers polygamous. *Br.*—Found near Port Jackfon, New South Wales. This is a delicate, fmooth, upright fpecies, whofe *leaves* have the afpect of fome *Hypericum* or *Euphorbia*. The *flowers* are of a yellowifh-green, tipped with purple, and are remarkable for forming a fimple corymbofe fmooth *fpike*, at the fummit of each branch. The fegments of the *calyx* are broad and obtufe; tube very flender, quite fmooth.

Sect. 4. *Leaves oppofite. Flowers axillary.* One fpecies.

P. *argentea*. Br. n. 31.—"Leaves lanceolate, filvery on both fides. Flowers from two to four together, axillary."—Gathered by Mr. Brown on the fouth coaft of New Holland. We have feen no fpecimen.

Sect. 5. *Leaves alternate.* Three fpecies.

P. *curviflora*. Br. n. 32.—Leaves elliptic-oblong; fmooth above; fomewhat filky beneath, like the branches, with depreffed hairs. Heads lateral, of few flowers. Calyx filky; tube curved; limb unequal.—Native of Port Jackfon. We have fine fpecimens from fir J. Banks. This is a humble fhrubby fpecies, with thyme-like fcattered *leaves*. The dried *flowers* are of a dull greenifh-brown; their tube externally very filky; fegments of the limb acute, one of them rather longer than the reft.

P. *gracilis*. Br. n. 33.—"Leaves oblong-linear, taper at the bafe; rather hairy beneath; fome of them oppofite on the branches. Heads lateral and terminal, of few flowers. Calyx filky; tube nearly ftraight; limb equal."—Gathered by Mr. Brown in the fouth part of New Holland.

P. *latifolia*. Br. n. 34.—"Leaves oblong; acute and hairy at the bafe; rather filky beneath. Heads many-flowered, fpiked; either terminal and feffile; or ftalked and oppofite to the leaves. Calyx villous."—Found by Mr. Brown in the tropical region of New Holland. We have feen neither of thefe two laft fpecies.

PIMELIA, in *Entomology*, a genus of the Coleoptera order of infects. The generic character is as follows: antennæ filiform; four feelers; thorax plano-convex, margined head exferted; fhells rather rigid; they are feldom found with wings. There are nearly 120 fpecies enumerated by Gmelin, divided into fections, according as their antennæ are moniliform, or entirely filiform; and thefe are fubdivided according to the fhape and ftructure of the feelers.

A. *Antennæ moniliform at the tip.*

a. *Feelers filiform.*

Species.

Striata. Black, glabrous; fhells with four fanguineous ftriæ. It is a native of India. The body is gibbous; antennæ brown at the tip; fhells united, the four ftreaks meeting at the tip.

Unicolor. Glabrous, black; the fhells are marked with three raifed obfolete lines. This is called the Tenebrio gibbus by Pallas. It is found at the Cape of Good Hope; as is the next.

Flavicollis. Glabrous, black; head white, villous behind.

Gibba. Black; thorax globular; fhells with an abbreviated lateral line. It is a native of India.

Globosa. Thorax globular and very fmooth; the fhells are fpinous behind. This is a native of the Cape.

Lævigata. Oblong, black; thorax globular; fhells very fmooth, immaculate. It inhabits Hungary.

Glabrata. Ovate, black; thorax globular; fhells very fmooth, immaculate. This is found in divers parts of Germany.

Hispida. Dull black; body rough, with erect ftiff hairs. It inhabits Alexandria.

Longipes. Black; fhells united, muricate; the legs are long. It is a native of feveral parts of Egypt.

Rustica. Thorax globular; grey; fhells with a fingle raifed angular line. It inhabits the Cape of Good Hope.

Muricata. Black; fhells obtufe, with muricate ftriæ. It inhabits fouthern Europe and the Eaft.

Tuberculata. Black; thorax rough; fhells with fubfpinous tubercles. It inhabits divers parts of Italy.

Variolosa. Black; thorax fmooth; fhells with obtufe tubercles; the legs are long. It inhabits the Cape.

Bi-punctata. Black; thorax globular, with two impreffed dots; the fhells are rugged, with three raifed fmooth ftriæ. This is a native of Italy.

Scabra. Black; fhells rough; the antennæ and legs are brown. This is found at the Cape.

Grossa. Black; fhells rough, with three fmooth raifed lines. It inhabits Barbary.

Angulata. Shells fpinous, with a lateral raifed ferrate line. It is a native of Alexandria.

Echinata. Thorax fpinous at the fides; fhells with raifed fpinous lines. It inhabits the Cape of Good Hope.

Dentata. Thorax glabrous; body black; fhells brown, with three raifed ferrate lines. It inhabits the Cape.

Porcata. Thorax fmooth, polifhed; fhells with three raifed lines, the fpaces between are rough, with raifed dots.

Maculata. Thorax black; fhells cinereous, fpotted with brown, with three raifed lines; the fecond flightly waved. It inhabits the Cape.

Serrata. Thorax variolous, fhells with three raifed lines; the interftices are rugged, and the legs long.

Minuta. Thorax fmooth and dufky; the fhells are cinereous and rough, with three raifed fmooth lines.

Rugosa. The thorax of this fpecies rough; the fhells are rugged, and narrower before.

Spinosa. Thorax margined, fpinous before and behind; the

the ſhells are marked with raiſed ſmooth ſtriæ. It is found in the ſouth of Europe, and alſo in the Eaſt.

Acuminata. Thorax margined, the fore and hind margins are ſpinous; the ſhells are ſmooth and united. A native of ſouthern Europe.

Reflexa. Thorax margined, and reflected at the edges; the ſhells are muricate, with a ſingle raiſed lateral line. Found in the Eaſt.

Fasciata. Of this the thorax is ſub-orbicular: the body is black; and the ſhells have two abbreviated yellow bands. It is an Indian inſect.

Collaris. Black; ſhells ſmooth, with a ſingle angle; the thorax is narrower than the ſhells; the head is depreſſed, carinate. Found in the ſouthern parts of Europe.

Carinata. Black; thorax orbicular; ſhells raiſed with three ſmooth lines. Inhabits the ſouth of Europe.

Ciliata. Black; depreſſed; thorax and ſhells ciliate, the latter reflected at the edges. It is a native of the Cape.

Lineata. Rounded and rough thorax; the ſhells have three lines of raiſed dots, and between theſe there are three lines. It inhabits Siberia.

Leucographa. Rounded and rough thorax; ſhells cinereous, with nine black raiſed lines. It is a ſmall inſect, and found in Saxony.

Glabra. Black; thorax rounded and ſmooth; the ſhells are very ſmooth. It inhabits Egypt, and varies very much in ſize.

Angustata. Glabrous; thorax narrowed behind; ſhells pointed. It inhabits the Eaſt. The body is entirely ſhining black.

Orbiculata. Glabrous; thorax orbicular; ſhells pointed. It is denominated the Tenebrio nomas by Pallas. It is a native of the Eaſt.

Cephalotes. Thorax ciliate at the fore and hind edges; the ſhells are very rough, with four raiſed lines, the lateral ones carinate and ſubſerrate. It inhabits the deſerts of Ural.

Convexa. Black, ſmooth; thorax orbicular, convex, truncate before. It is found in divers parts of Europe and Africa.

Linearis. Black, ſmooth; legs ferruginous; antennæ very ſhort. It inhabits Sweden.

Pubescens. Ovate, pubeſcent, opaque; ſhells with each four denticulate ribs. It is found in Egypt.

Aurita. Thorax margined, dilated on the fore part; ſhells bicarinate, with two gibboſities. It inhabits Mauritania, as does the next.

Didyma. Thorax widely margined, two-horned behind; ſhells angular, with two gibboſities.

Caspica. Ovate, ſlightly depreſſed; thorax excavated before and behind; ſhells carinate on each ſide, with alternate rough and ſmooth bands. A native of the Caſpian ſea.

Subglobosa. This, as its name imports, is ſubglobular; ſhells with ſmooth raiſed dots, and about four ribs, the outmoſt are carinate and crenulate. It is the Tenebrio ſubgloboſus of Pallas. It inhabits ſouthern France, and the deſerts of Tartary. It moves very ſlowly, and is infeſted with the Gordius; and ſuppoſed to be a variety only of the Pimelia rugoſa.

Silphoides. Sides of the thorax pointed behind, jagged before; ſhells with three ſmooth ſtriæ. A native of Mauritania.

Tibialis. Black, ſmooth; fore-ſhanks compreſſed, one-toothed. It inhabits Africa and Spain.

Femoralis. Black, ſmooth; thighs thick, channelled beneath. It is found in divers parts of Germany.

Striatula. Black; ſhells ovate-oblong, ſtriate. A native of Spain.

Laticollis. Oval, depreſſed, deep black, ſmooth; thorax very broad, margined, excavated before, and truncate behind; the ſhells are ſubſtriate. Found at the Cape of Good Hope.

Vittata. Gibbous, black; ſhells united, glabrous, with three ſcarlet ſtriæ and ſutures on each ſide; the legs are unarmed.

b. *Feelers clavate.*

Gages. Black; the thorax is a little rounded; the ſhells are mucronate and very ſmooth. Inhabits the ſouthern parts of Europe. It reſembles the P. mortiſaga, but is twice as large.

Sulcata. Shells mucronate and grooved. It is found in the Eaſt; the ſhells are united with eight or nine ſmooth grooves. This inſect is ſold in Turkey as a ſpecific againſt pains in the ears, and the bite of ſcorpions, and is boiled with butter, and eaten by the Turkiſh ladies for the purpoſe of making them grow fat.

* Mortisaga. Black; ſhells mucronate, ſub-punctured. Found in various parts of Europe, as well as in this country. This inoffenſive animal is regarded as a preſage of the death of one in the family, by the common people in Sweden, if it is ſeen crawling about the houſe.

Excavata. Thorax angular behind; ſhells with indented dots, ſomewhat pointed. It is a native of Coromandel.

Granulata. Black, depreſſed; ſhells with ſub-ſpinous tubercles. It inhabits the Cape of Good Hope, as does the next.

Buprestoides. Ovate, black; ſhells united and very ſmooth.

Dermestoides. Black, ovate; ſhells obſoletely ſtriate; ſhield emarginate. It is a native of Saxony.

Obtusa. Thorax angular behind; body black; ſhells obtuſe, ſtriate. It inhabits Coromandel. This is the Blaſis ſtriata of Fabricius.

Capensis. Ovate, depreſſed, black; thorax with dilated margins; it has four fore-ſhanks one-toothed. Found at the Cape.

Emarginata. Black, ſhells with crenate ſtriæ; lip emarginate. It inhabits Morocco.

Granulosa. Black; ſhells with three raiſed lines, and ſmall raiſed dots between them; thorax emarginate. This is an African inſect.

Sublævigata. Depreſſed, black; ſhells with three raiſed ſmooth lines. A native of Morocco.

Tristis. Black; ſhells grooved; the grooves ſmooth. Found in the ſandy plains of Barbary.

Serratula. Thorax thickened at the edge; ſhells with three raiſed crenate lines. It inhabits the Cape of Good Hope.

Femorata. Black; hind-thighs channelled beneath, and covered with ferruginous down. A native of Germany.

Tibiata. Black; ſhells ſtriate; fore-ſhanks dilated and triangular. It is found at the Cape of Good Hope.

Crenata. Thorax angular behind; of a grey-brown colour; ſhells with crenate ſtriæ, obtuſe. It inhabits Coromandel.

Helopioides. Oblong, black; ſhells very ſmooth. It is an European inſect.

Punctata. Black; antennæ ferruginous; ſhells ſtriate, and

and punctured. It is a native of the South American iſlands.

CLATHRATA. Black; ſhells latticed; antennæ ferruginous at the tip. It inhabits South America.

SPECIOSA. Subovate, bronzed, winged; ſhells highly poliſhed, ſtriate, with coppery and green lines. It inhabits Brazil.

CHRYSOMELOIDES. Ovate, very rough; thorax longitudinally ridged; ſhells with three tuberculate lines. A native of Mauritania.

COSTATA. Subglobular, roughiſh, opaque; ſhells with each three crenulate ribs, the outmoſt carinate. A native of Siberia.

TORULOSA. Ovate, ſubglobular; ſhells tuberculate, convex, without ribs. It is found at the Cape of Good Hope.

AGRICOLA. Pale rufous; head and thorax black. It inhabits Germany.

SABULOSA. Black; ſhells rugged, pointed behind. Found in France, as is the next.

OCTO-STRIATA. Black; ſhells with eight punctured ſtriæ diſpoſed in pairs.

B. *Antennæ entirely filiform.*

a. *Feelers four, filiform.*

TRICUSPIDATA. Thorax with three teeth before; the body is of a grey colour. It is an Arabian inſect.

SIMILIS. Thorax duſky, with three teeth; diſk of the ſhells whitiſh, with three brown lines. Found in Barbary.

CRISTATA. Thorax with three teeth, creſted; body variegated. Found in Arabia.

RETICULATA. Thorax angular at the ſides; ſhells reticulate. It inhabits the Cape of Good Hope; as do the two following.

CORRUGOSA. Thorax ſmooth; gloſſy-black; ſhells rugged, with a ſingle raiſed line.

VITTATA. Thorax ſubangular; ſhells black, with two white fillets, and a ſingle raiſed line.

b. *Fore-feelers hatched-ſhaped, hind-ones clavate.*

LAMINATA. Black; thorax nearly ſquare, ſmooth; ſhells grooved; fore-ſhanks incurved, with a round ferruginous appendage at the tip. It inhabits India.

PUNCTULATA. Black; thorax ſquare, the edges ſlightly toothed; ſhells ſtriate, punctured. It inhabits India.

* CÆRULEA. Blueiſh; thorax ſuborbicular; ſhells ſtriate. This is found in this country, and other parts of Europe.

LANIPES. Bronzed; ſhells ſerrate and pointed. It is a native of Germany.

MARGINATA. Black; ſhells with a ſanguineous edge all round. It inhabits Guinea. The ſhells are ſtriate, black, with a blue gloſs; the breaſt is rufous.

ÆRUGINOSA. Green bronzed; antennæ, ſhells, and legs black. Found at the Cape of Good Hope.

BICOLOR. Above dull braſſy; beneath black; ſhells ſtriate. It inhabits the South American iſlands.

* SERRATA. Black; claws ferruginous; feelers projecting. This is an Engliſh inſect, and found in other parts of Europe.

BARBATA. Black; feelers projecting; legs yellowiſh. A native of Saxony.

CANICULATA. Black; thorax channelled, impreſſed on each ſide; the ſhells are ſtriate; the feelers projecting. This is a native of Saxony.

HÆMORRHOIDALIS. Head and thorax azure; ſhells green, with crenate ſtriæ; the tail is rufous. It is found in India.

LURIDA. Black; antennæ and legs brown. Inhabits Brazil.

LÆVIS. Black; thorax channelled, tapering behind; ſhells ſmooth. It inhabits Saxony.

EQUESTRIS. Black; ſhells with an abbreviated gold band. It inhabits Brazil.

MAURA. Black; thorax rounded on each ſide, ſmooth; ſhells with indented dots. It inhabits the Eaſt Indies.

MORIO. Black; thorax ſquare, ſmooth; ſhells with punctured grooves. It inhabits North America.

NIGRITA. Black; thorax rounded at the edges; ſhells with crenate grooves. It inhabits Tranquebar.

PICICORNIS. Ovate, black; ſhells ſtriate; antennæ and abdomen piceous. It inhabits the Eaſt Indies.

RUFIPES. Black; ſhells, antennæ, and legs rufous. Found in New Holland.

LONGIPES. Black; ſhells ſtriate; legs long; ſecond pair of ſhanks bearded. It inhabits the equinoctial parts of Africa.

CAPENSIS. Ovate, black; thorax ſmooth; ſhells ſtriate. It inhabits the Cape.

MARGINATA. Ovate; thorax thickened at the edges; ſhells ſtriate and ſmooth. It inhabits the Cape.

ATRA. Black; ſhells ſtriate; antennæ and legs brown. It is a native of Germany.

* ANGLICA. Black; thorax rounded before; ſhells ſtriate, punctured; antennæ rufous at the tip. It is a rare inſect, but a native of England.

HOTTENTOTTA. Black; ſhells with crenate ſtriæ. This is found in France.

BANKII. Black; ſhells grooved, punctured; fore-thighs ſharply toothed. It is found in Coromandel.

UNDATA. Black; thorax rufous, with black ſpots; ſhells rufous, with waved black bands. It inhabits Cayenne.

* QUISQUILIA. Black; antennæ and legs ferruginous. It inhabits divers parts of Europe, and is found in filth and manure.

FLAVIPES. Brown; mouth, antennæ, and legs ferruginous; ſhells with crenate ſtriæ. It inhabits the South American iſlands.

RUFICOLLIS. Ferruginous; ſhells ſtriate, black. It inhabits Saxony.

CYANEA. Blue; thorax punctured; ſhells ſtriate. It inhabits Germany.

VIOLACEA. Cylindrical, varied with fine poliſhed blue and violet; abdomen red behind; ſhells ſtriate, punctured.

LEUCOGRAPHA. Ovate; thorax very rough, uneven; ſhells carinate, rough, with longitudinal, whitiſh, ſmooth ſtripes.

BUPARIA. Winged, black, glabrous; thorax lunate; jaws ſtrong, toothed, as long as the head. It inhabits Spain, is deſcribed to be of the ſize of Lucanus interruptus, and it reſembles the Tenebrio foſſor.

PIMENI, in *Geography*, a town of Naples, in Calabria Ultra; 17 miles N.E. of Nicotera.

PIMENTA, or PIMENTO, in *Botany*, *All-ſpice*, or *Jamaica Pepper*, a ſpecies of the *Myrtus*, the *Myrtus pimenta*. (See MYRTUS.) It grows plentifully on the hilly parts of Jamaica, and is much cultivated there; becauſe of the great profit from the cured fruit ſent in great quantities yearly into Europe.

It flowers in June, July, and Auguſt, ſooner or later, according to its ſituation and the different ſeaſons for rain; and after its flowers, the fruit ſoon ripens. The flowers, with every part of the tree, breathe an aromatic fragrance.

Its

Its fruit is called *all-ſpice*, from its taſte being ſuppoſed to reſemble that of many different ſpecies mixed together.

There is little difficulty in curing and preſerving this fruit for uſe, which is done thus: the negroes climb the trees and pull off the twigs with the unripe green fruit, and afterwards carefully ſeparate the fruit from the twigs, leaves, and ripe berries; which done, they expoſe them to the ſun from its riſing to ſetting, for many days, ſpreading them thin on cloths, turning them now and then, and carefully avoiding the dews. By this management they become a little rugoſe or wrinkled, dry, and from a green change to a brown colour, and then they are fit for the market.

The ripe berries are very carefully ſeparated from thoſe to be cured; becauſe their wet and plenteous pulp renders them unfit for cure.

The berries that are fully ripe loſe the aromatic warmth for which they are ſo much eſteemed, and acquire a taſte perfectly reſembling that of juniper berries, which renders them an agreeable food for the birds, the moſt induſtrious planters of theſe trees, which devouring them greedily, and muting the ſeeds, afterwards propagate theſe trees in all parts of the woods.

After the above deſcribed proceſs is completed, which is known by the colour and rattling of the ſeeds in the berries, they are put up in bags or hogſheads for the market. The aromatic odour and warm pungent taſte of the pimento are qualities, which reſide chiefly in the capſule, or rather cortical part of the dried berry. Its virtues are extracted by water, alcohol, and ether. The watery infuſion is of a brown colour, and reddens litmus infuſion. With ſolution of ſulphat of iron it immediately ſtrikes a deep black colour, and ſlowly lets fall a precipitate. Nitrate of mercury precipitates it of a yellowiſh-brown; ſuperacetate of lead of a dirty green; and nitrate of ſilver of a deep reddiſh-brown colour. It alſo forms a precipitate with the infuſion of yellow cinchona bark. The ſulphuric and muriatic acids redden it, and throw down pale roſe coloured precipitates. The nitric acid forms no precipitate, but gives it a yellow hue. The alcoholic tincture is rendered milky, and after a time precipitated by water; the ethereal, when evaporated in water, depoſits drops of a greeniſh-yellow volatile oil, a pellicle of a pungent nauſeous-taſted reſin, and ſome extractive. Hence pimento appears to contain a volatile oil, reſin, extractive, tannin, and gallic acid.

For dietetic purpoſes, to which it is chiefly applied, it is accounted the beſt and moſt temperate, mild, and innocent of common ſpices, and fit to come into greater uſe, and to gain more ground than it hath yet done. It ſurpaſſes moſt of the Eaſt Indian aromatics in promoting the digeſtion of meat, attenuating tough humours, moderately heating, ſtrengthening the ſtomach, expelling wind, and doing thoſe friendly offices to the bowels, we generally expect from ſpices. Phil. Tranſ. N° 192.

This ſpice has been alſo long employed in the ſhops as a ſuccedaneum to the more coſtly oriental aromatics. Diſtilled with water, it yields an elegant eſſential oil, ſo ponderous as to ſink in water, in taſte moderately pungent, in ſmell and flavour approaching to oil of cloves, or a mixture of thoſe of cloves and nutmegs: the remaining decoction, inſpiſſated, leaves an extract ſomewhat ungrateful but not pungent. To rectified ſpirit it imparts, by maceration or digeſtion, the whole of its virtue, together with a browniſh-green tincture. In diſtillation it gives over very little to this menſtruum, nearly all its active matter remaining concentrated in the inſpiſſated extract.

Pimento is ſtimulant and tonic. It is uſeful as an adjunct to bitters in dyſpepſia attended with much flatulence, and in arthritic and hyſterical affections. The watery infuſion of it ſweetened with ſugar, and with the addition of a little milk, is readily taken by children, and ſerves as an excellent cordial in malignant meaſles, ſcarlatina, confluent ſmall-pox, and the other exanthemata, when the fever aſſumes the typhoid type. But its principal uſe in medicine is to cover the diſagreeable taſtes of other remedies, or to give them warmth. The doſe of the berries is from grs. v to ℈ij in powder, or in their entire ſtate. The officinal preparations are the following; *viz*. Aqua pimenta, L. E. D. Oleum pimentæ, L. E. D. Pilulæ opiatæ, E. Spiritus pimentæ, L. D. Syrupus rhamni, L.

The "Aqua pimentæ" of the London college, "Aqua myrti pimentæ," Edinb., "Aqua pimento," Dub., or pimenta water, is prepared by macerating half a pound of pimenta berries bruiſed in a pint of water for 24 hours; and by diſtilling with a ſufficient quantity of water to prevent empyreuma, a gallon (10 pounds, Edinb.)

This water has the odour and aromatic quality of the Jamaica pepper, but it is not very agreeable to the taſte. It is uſed as a carminative in dyſpepſia.

"Oleum pimentæ," L.E.D. (ſee Oil *of Jamaica Pepper*), "Pilulæ opiatæ," (ſee Pills, *Opiate*), "Spiritus pimentæ," L., "Spiritus pimento," Dub., Spirit of pimenta, is prepared by macerating for 24 hours two ounces (three ounces, Dub.) of pimenta berries bruiſed in a gallon of proof ſpirit, with water ſufficient to prevent empyreuma; and then diſtilling a gallon by gentle heat. "Spiritus fructus myrti pimentæ," Edinb., Spirit of pimenta, is prepared with half a pound of bruiſed pimenta berries, in the ſame manner as ſpirit of caraway. This is an uſeful carminative in flatulent colic, atonic gout, and dyſpepſia.

Syrupus *Rhamni*. See *Syrupus* Rhamni.

PIMERIA, in *Geography*, a province in the domain of New Biſcay, ſo called from the Pimas, a ſavage tribe. It is divided into two diſtricts, the higher and the lower, and extends more than 100 leagues to the N. of Sonora. The ſavages here are rather pacific, and friends of the Spaniards. The climate is moiſt and cold, the rains being ſometimes continued during a whole week in winter, while many torrents deſcend from the Sierra Madre. The Spaniards have left this province almoſt a deſert, on account of the frequent invaſion of the Apaches.

PIMOCHA, a town of South America, in the audience of Quito; 36 miles N.N.E. of Guayaquil.

PIMOLISA, in *Ancient Geography*, a fortified place of Cappadocia, in Pontus, on this ſide of the river Halys, and which gave name to the country of "Pimoliſena," in the environs of this river.

PIMP-Tenure, in *Law*, a kind of tenure mentioned in our old writers, "Willielmus Hoppeſhort, tenet dimidiam virgatam terræ, per ſervitium cuſtodiendi ſex damiſellas ſcil. meretrices, ad uſum domini regis." 12 Ed. I.

PIMPELGONG, in *Geography*, a town of Hindooſtan, in the circar of Kitchwara; 15 miles E. of Saurungpour.

PIMPERNEL, in *Botany* and the *Materia Medica*. See Anagallis.

Pimpernel, *Water*, a ſpecies of ſpeedwell or *veronica;* which ſee.

Pimpernel, *Round-leaved Water*. See Samolus.

Pimpernel, *Yellow, of the Woods*. See Lysimachia.

PIMPINELLA, is ſuppoſed by Ambroſinus, whoſe opinion is adopted by Linnæus, to be a corruption of *bipinella*, or *bipennula*, words expreſſive of the pinnate, or feather-like, ſtructure of the foliage. Linn. Gen. 145. Schreb. 195. Willd. Sp. Pl. v. 1. 1471. Mart. Mill. Dict.

Dict. v. 3. Sm. Fl. Brit. 331. Ait. Hort. Kew. v. 2. 159. Juſſ. 219. Lamarck Illuſtr. t. 203. (Aniſum; Gærtn. t. 23.)—Claſs and order, *Pentandria Digynia.* Nat. Ord. *Umbellatæ.*

Gen. Ch. *General umbel* of numerous rays; *partial* of ſtill more. *General* and *partial involucrum* wanting. *Perianth* ſcarcely diſcernible. *Cor.* Univerſal nearly uniform; flowers all fertile; partial of five, nearly equal, inflexed, heart-ſhaped petals. *Stam.* Filaments five, ſimple, longer than the petals; anthers roundiſh. *Piſt.* Germen inferior; ſtyles two, very ſhort; ſtigmas capitate, nearly globoſe. *Peric.* none; the fruit ovate-oblong, ſeparable into two parts. *Seeds* two, oblong, contracted towards the top, convex and ſtriated on the outer ſide, flat on the inner.

Eſſ. Ch. General and partial involucrum wanting. Petals uniform, inflexed. Fruit ovate-oblong, ſtriated. Stigmas nearly globoſe.

1. P. *ſaxifraga.* Common Burnet-Saxifrage. Linn. Sp. Pl. 378. Fl. Dan. t. 669. Jacq. Auſtr. t. 395. Engl. Bot. t. 407. (Bipinella, five Saxifraga minor; Ger. Em. 1044.)—Leaves pinnate, variouſly cut; the radial leaflets roundiſh; the uppermoſt linear. Seeds ſmooth.—Native of dry gravelly or lime-ſtone paſtures and hills, in various parts of Europe; frequent in England, flowering in July and Auguſt. The *root* is perennial, woody, aromatic, very hot and pungent. *Herb* roughiſh, and ſomewhat downy. *Stems* erect, rigid, round, ſtriated, rather zigzag; the flowering branches elongated, and nearly naked. The leaflets of the radical *leaves* are ovate, obtuſe, or roundiſh, very deeply and irregularly cut, ſome of them, from the ſame root, doubly pinnatifid in the moſt regular manner; the *leaves* on the upper part of the ſtem are ſimply pinnatifid, and linear; and the uppermoſt of all minute, as if abortive, conſiſting of little more than a lanceolate, concave, membranous *footſtalk.* The *umbels* are terminal, ſolitary, naked, and ſmooth, with angular ſtalks. *Flowers* ſmall, white or cream-coloured, almoſt perfectly regular. *Stigmas* capitate, which is unfortunately omitted in Engl. Bot., ſome of the *flowers* being occaſionally found incomplete in that reſpect, as there repreſented. *Seeds* ſmall, ſtriated, ſmooth, crowned with the fleſhy receptacle of the flower. *P. diſſecta.* Retz. Obſ. faſc. 3. 30. t. 2. Willd. n. 4. Ehrh. Herb. 42; appears to us a mere variety, with triply pinnatifid leaves. Ehrhart's ſpecimen, at leaſt, is not ſpecifically different from *ſaxifraga*, except in its ſmooth *ſtem*, a variable character.

2. P. *nigra.* Black-rooted Burnet-Saxifrage. Willd. n. 2. Berolin 110. (Saxifragia hircina minor, foliis ſanguiſorbæ; Bauh. Hiſt. v. 3. part 2. 111.)—Stem ſtriated, hairy. Leaves pinnate, downy; the radical ones with inverſely heart-ſhaped, cut, obtuſely toothed leaflets; thoſe on the ſtem bipinnate, their leaflets wedge-ſhaped, toothed.—Native of dry ground in Germany. We know it not, but we follow Willdenow's *Prodromus Berolinenſis*, in preference to his Sp. Pl., in the character, as agreeing beſt with Roth's Fl. Germ. v. 2. 342. The latter author deſcribes "the terminal leaflet of the radical *leaves* conſtantly three-lobed." So it often is in *P. ſaxifraga.* The *root* of *P. nigra* is ſaid to diſcharge a blue milky fluid, when wounded.

3. P. *magna.* Great Burnet-Saxifrage. Linn. Mant. 2. 219. Willd. n. 3. Engl. Bot. t. 408. (P. major; Hudſ. 127. Fuchſ. Hiſt. 608. Jacq. Auſtr. t. 396. P. ſaxifraga; Ger. Em. 1044. Matth. Valgr. v. 2. 379.)—Leaves pinnate; leaflets ovate, pointed, cut; the terminal one three-lobed. Stem angular, furrowed, ſmooth.—Native of various parts of Europe. Found with us chiefly on a chalky or lime-ſtone ſoil, in rather hilly places, flowering in July and Auguſt. The *root* is larger than that of the firſt ſpecies, but weaker in flavour and qualities. Whole plant larger, diſtinguiſhed by the uniformity of its *leaves*, which are pointed, and doubly ſerrated, ſmooth, and of a lighter green. *Stem* ſmooth, remarkably angular and furrowed. *Umbels* large, always white in England. Jacquin repreſents them of a pale bluſh, though he deſcribes them as generally white, except in ſubalpine ſituations. On the alps of Switzerland, France, Savoy, &c. this ſpecies is always found with beautiful pink *flowers.* This is P. flore rubro; Riv. Pentap. Irr. t. 81. We have often, in contemplating its beauty, wiſhed to detect ſome ſpecific diſtinction, but in vain. Another acknowledged variety, though much differing in habit, is *P. orientalis*, Gouan. Illuſtr. 21. t. 15. Jacq. Auſtr. t. 397. (Pimpinella; Riv. Pentap. Irr. t. 80.)—In this moſt of the *leaflets* are deeply, and even doubly, pinnatifid, with linear-lanceolate, entire, not ſerrated, ſegments. Without the radical *leaves*, which agree with the common appearance of *P. magna;* and the weighty authority of Jacquin, who has traced its variations; few perſons would believe this to be but a variety. Willdenow ought to have marked it γ, as differing from his β.

4. P. *Tragium.* Downy-ſeeded Burnet-Saxifrage. Villars Dauph. v. 2. 605. (Tragium alterum Dioſcoridis; Column. Phytobaſ. 75. t. 76. ed. 2. 61. t. 17, excluding Tournefort's ſynonym.)—Leaves pinnate; leaflets wedge-ſhaped, cut; the uppermoſt linear and entire. Seeds downy.—Found by Villars near Grenoble, at the foot of the mountain of St. Juſte, near St. Paul of the three caſtles, amongſt red ochry ſand and foſſil ſhells. We have a ſpecimen from M. Thouin. Authors have paſſed over this ſpecies, though it appears to us very diſtinct, eſpecially in its downy *ſeeds*, which ſerve to aſcertain the ſynonym of Columba, though his plate muſt ſurely have been taken from a ſpecimen of *P. ſaxifraga;* at leaſt his *leaves*, except that on the middle of the *ſtem*, give no idea of our plant. The *root* of *P. Tragium* is woody, branched at the top, very pungent. *Stems* from ſix to twelve inches high, branched, ſpreading, round, ſtriated, downy, almoſt leafleſs. Radical *leaves* numerous, ſimply pinnate, two inches long, rigid, minutely downy; wedge-ſhaped, not rounded, very acutely cut into about three ſegments. Villars ſays the leaflets of the firſt year's growth are more rounded. *Umbels* finely downy. *Stigmas* capitate. *Seeds* ovate, angular rather than ſtriated, uniformly covered with fine, ſhort, denſe pubeſcence.

5. P. *bubonoides.* Round-leaved Burnet-Saxifrage. Broter. Luſit. v. 1. 462. Phytogr. faſc. 1. 41. (Apium macedonicum; Luſit. Griſl. Virid. 19, excluding the ſynonym. A. luſitanicum rotundifolium; Tourn. Inſt. 305.)—Leaves twice or thrice pinnate, rounded, obtuſe, crenate. Stem panicled. Umbels and ſeeds downy.—Native of ſandy barren places in Portugal. *Brotero.* Loefling ſent ſpecimens from St. Ubes, with Tournefort's ſynonym, to Linnæus, who laid them undetermined into his genus of *Bubon.* We have others gathered by the Abbé Durand, in July, near Salée in Barbary. This is a ſtriking and moſt diſtinct ſpecies, with all the characters of a *Pimpinella.* *Root* perennial, acrid, externally green. *Stem* often ſolitary, ſometimes three or four from one root, herbaceous, annual, twelve or eighteen inches high, round, downy, thickiſh, much branched, and panicled, bearing a multitude of white *umbels*, very downy in every part; the *branches* and *ſtalks* accompanied by broad, ſolitary, ovate, often recurved *bracteas*, or rather abortive leaf-ſtalks. Radical *leaves* large, green, finely veined, ſlightly downy, twice or thrice pinnate;

nate; each leaflet near an inch long, rounded and obtuse, strongly crenate; oblique, entire, and cut away, as it were, at the base.

6. P. *capensis*. Cape Burnet-Saxifrage. Thunb. Prodr. 51. Willd. n. 6.—"Leaves thrice compounded; their segments acute. Stem striated."—Found at the Cape of Good Hope.

7. P. *peregrina*. Nodding Burnet-Saxifrage. Linn. Sp. Pl. 378. Willd. n. 7. Ait. n. 4. Jacq. Hort. Vind. v. 2. 61. t. 131. (Daucus tertius Dioscoridis, secundus Plinii; Columm. Ecphr. 108. t. 109.)—Radical leaves pinnate, rounded, crenate; upper stem-leaves wedge-shaped, cut. Young umbels pendulous. Seeds hispid.—Native of Italy, Spain, and France. Cultivated by Parkinson in 1640. *Root* perennial, spindle-shaped, white, aromatic and acrid. *Stem* eighteen inches high, erect, round, downy, not much branched. Radical *leaves* simply pinnate, rounded and crenate; the rest composed of narrow wedge-shaped leaflets; all somewhat rough or downy. *Umbels* few, large, white, perfectly pendulous, as if dying, before the *flowers* expand. *Seeds* ovate, minutely bristly.

8. P. *Anisum*. Anise. Linn. Sp. Pl. 379. Willd. n. 8. Ait. n. 5. Woodv. Med. Bot. t. 180. (Anisum; Riv. Pentap. Irr. t. 73. Ger. Em. 1035.)—Radical leaves three-cleft; stem-leaves acutely laciniated. Germen downy. —Native of Egypt. A hardy annual, but seldom ripening its seeds plentifully in our gardens. What are required for medical use, as an agreeable aromatic and cordial, are imported from Spain and Malta. The *herb* is a foot high, branched, slightly rough or downy, known by its jagged sharp *leaves*. *Umbels* always erect, white.

9. P. *dichotoma*. Fork-leaved Burnet-Saxifrage. Linn. Mant. 58. Willd. n. 9.—Leaves repeatedly compound, linear, channelled, acute. Footstalks with a membranous dilated wing. Stem panicled. Seeds globose, rough.—Native of Spain; sent by Loeffling to Linnæus, who alone has described it, nor do we find it any where figured. The *stem* is about a foot high, very much branched and panicled, with numerous white *umbels*. *Leaves* fleshy, roughish, in narrow channelled subdivisions, so that this species might well have been termed *abrotanifolia*. Their broad *footstalks* are conspicuous for a fine, broad, membranous, snow-white border.

10. P. *dioica*. Dwarf Burnet-Saxifrage, or Rock Parsley. Linn. Syst. Veg. ed. 13. 241. Willd. n. 10. Engl. Bot. t. 1209. (P. pumila; Jacq. Austr. t. 28. P. glauca; Linn. Sp. Pl. 378. Willd. n. 5. Seseli pumilum; Linn. Sp. Pl. 373. Peucedanum pumilum; Ger. Em. 1054.)—Leaves twice or thrice compound, linear, smooth. Umbels panicled. Flowers dioecious. Seeds ovate, smooth.—Native of Italy, Switzerland, France, and Austria; found on lime-stone rocks, in the south of England, but rarely. We no longer scruple to unite all the above synonyms of Linnæus, on the authority of his own specimens. This species is of humble growth, smooth, glaucous, with a stout, zigzag, striated, purplish *stem*, divided into many alternate spreading branches. The *umbels* are disposed in a panicled manner, on reddish stalks. *Flowers* white, perfectly dioecious in effect, though not entirely in structure. *Seeds* roundish-ovate, striated, quite smooth. Dr. Wade has met with this rare plant, in great abundance, in pastures near the church of Athby, county of Meath, Ireland. Dr. Sibthorp found it on the summits of mount Athos, and the Bithynian Olympus.

PIMPINELLA, in *Gardening*, contains a plant of the annual kind, of which the species cultivated is the anise (P. anisum).

In these plants the seeds have an aromatic smell, and a pleasant warm taste, accompanied with a considerable degree of sweetness.

Method of Culture.—The seeds should be sown in the early part of April, on a dry warm border, where the plants are to remain; being afterwards properly thinned out, and kept free from weeds. These plants, however, seldom afford much profit by their seeds in this climate.

They produce variety in the borders, &c. of pleasure-grounds, as well as in pots in other places, when cultivated in that way.

PIMPLA, or PIMPLEUS, in *Ancient Geography*, one of those mountains which separated Macedonia from Thessaly, and which were consecrated to the Muses.

PIMPLE, in *Medicine*, a small pustule arising on the face.

By mixing equal quantities of the juice of house-leek, *sedum minus*, passed through paper, and of spirit of wine rectified by itself, a white coagulum of a very volatile nature is formed, which Dr. Burghart commends for curing pimples of the face; and says, that the thin liquor separated from it, with sugar-candy, is an excellent remedy for thick viscid phlegm in the breast. Satyr. Silesiac. Spec. 4. Ob. 2.

PIMPRAMA, in *Ancient Geography*, a town of India, towards the source of the river Indus, according to Arrian.

PIMSAN-IM, in *Geography*, a town of Chinese Tartary; 35 miles S.W. of Ning-yuen.

PIN, in *Commerce*, a little necessary implement, chiefly used by the women in adjusting their dress.

The form and application of this little article need no description; but its consumption, and the number of hands it employs, are too considerable to be passed by unnoticed.

Pins are now mostly made of brass-wire: formerly they likewise made them of iron-wire, which, being blanched, like the others, passed for brass; but the ill effect of those pins has almost altogether discarded their use. The French, however, could not be driven off from them without several arrets of parliament. By a sentence of the lieutenant de police, July 1695, the seizure of some millions of those pins was confirmed, and the pins condemned to be burnt by the common executioner.

The pins most esteemed in commerce are those of England. The method of manufacturing this useful article, that has been long practised, is as follows. The brass wire, of which these implements are now almost wholly made, is generally too thick for being cut into pins. It is, therefore, reduced in size, by causing it to pass through a small hole in a piece of iron. When it has been reduced to a proper size, it is straightened, and subsequently cut into proper lengths; and again afterwards cut into smaller ones, each length being sufficient for making several pins. Each end of these pieces is pointed, so as to be sharp enough for penetrating, without difficulty, through linen, paper, &c. by either men or boys, seated before two small grinding-stones, or steel-mills, that are turned by a wheel, either by means of machinery or of the hand. These stones, or steel-mills, are used for making the rough point, and for smoothing them; and, therefore, they are careful to turn the wire, so as to render the points uniform and regular. The pin is afterwards cut off to the length that is wanted, from each end; and the process is repeated; till the whole of the length is pointed. The manufacture of the head is performed by the following operations. A piece of wire, suitable for heads, is spun on another; and thus the inside wire occasioning the upper

upper wire to be hollow, when drawn off, is then in the ftate required for being cut into heads: this is done by fhears, every two rounds of the wire making a fingle head. The next procefs is that of heading the lengths, which is done by the operators or work-people taking up a fingle length, and thrufting it among the heads, and then immediately placing it under a heavy weight or hammer; when receiving the neceffary blow, it is made fecure; and thus the pin is completed in the firft ftate. After this it is to be blanched or whitened, which is accomplifhed by putting the pin in a copper, containing tin and the lees of wine. When this is completed, the pin is in a ftate for fale, at the option of the buyer, either in a loofe ftate, or ftuck in paper for the convenience of the confumer.

Some fuccefsful attempts have been lately made by the well-known manufacturers, Meffrs. Durnford, Francis, and Co., of Gracechurch-ftreet, London, for putting on the heads of this very ufeful little article, with greater expedition and uniformity than had been previoufly done by others. We are not at liberty to difclofe the procefs, which is ingenious, practicable, and expeditious; but to every effort for the improvement of this, and of every other article of Britifh manufacture, we cannot but wifh fuccefs.

The perfection of pins confifts of the ftiffnefs of the wire, and its blanching; in the heads being well turned, and the points filed.

The London pointing and blanching are in moft repute; becaufe our pin-makers in pointing ufe two fteel-mills, (which are alfo occafionally ufed in the country,) the firft of which forms the point, and the latter takes off all irregularities, and renders it fmooth, and as it were polifhed; and, in blanching, ufe block tin, granulated: whereas in other parts they ufe a mixture of tin, lead, and quickfilver; which not only blanches worfe than the former, but is alfo dangerous, on account of the ill quality of that mixture, which renders a puncture with a pin thus blanched very difficult to be cured.

The confumption of pins, and the number of artificers employed in the manufacture of them, are incredible. In Paris alone, there were anciently above one thoufand people employed in it; and after the decline of this manufacture in the city, there have been annually fold above fifty thoufand crowns worth of the pin-wire to the pin-makers of the neighbouring places, all brought thither from Stockholm. In the little town of Rugle, in Normandy, there were computed at leaft five hundred workmen employed in the pin manufacture; the whole town being peopled with them. Several thoufand perfons are employed in this manufacture, in various parts of our own country. Eftablifhments of this kind are to be found in the Metropolis, Warwickfhire, Gloucefterfhire, Effex, &c.

Notwithftanding that there is fcarcely any commodity cheaper than pins, there is not any one that paffes through more hands before they come to be fold. They reckon twenty workmen fucceffively employed in each pin, between the drawing of the brafs-wire, and the fticking of the pin in the paper.

Pins are diftinguifhed by numeros; the fmaller called from N° 3, 4, 5; thence to the 14th; whence they are only accounted by two to two, *viz.* N° 16, 18, and 20, which is the largeft fize.

Befides the white pins, there are alfo black ones made for mourning, from N° 4, to N° 10. Thefe are ufually of iron-wire.

Laftly, there are pins with double heads, of feveral numeros; ufed by the ladies to fix the buckles of their hair for the night, without danger of being difturbed by their pricking, &c.

The manufacture of both brafs and iron pins is thought by fome perfons to be in a degree injurious to the pointer; as it is imagined he imbibes, in the courfe of fome years, a quantity of the duft which flies off the wire, and which, in that cafe, muft be pernicious. He is alfo liable, from the conftant preffure of his thumb on the ftones, to a weaknefs in it, which not unfrequently renders him incapable of continuing the operation of pointing.

We are forry to learn that the pin manufacture is lefs profperous than it was fome years ago. This decline is partly owing to the diminifhed confumption of this article by our fair country-women, and of courfe partly to the excefs of the quantity made above the regular demand; which has occafioned to the mafter-manufacturer not only an inconvenience, but a difproportionate return of profit for the capital which it employs. Upon the whole, it is thought, that this ufeful clafs of perfons is decreafing in number; and that there are no very encouraging expectations of the manufacture's foon reviving and flourifhing.

The firft mention of pins that occurs in the Englifh ftatute-book, is found in the ftatute of Richard III. in 1483, prohibiting foreign manufactures; and it appears from the manner in which pins are defcribed in a ftatute of the 34th and 35th of Henry VIII. cap. 6, A.D. 1543, and the labour and time which the manufacture of them would require, that they were a new invention in this country, and probably but lately brought from France. However, in about three years time, they fell into the prefent ingenious and expeditious manner of making them.

One of the articles of the ftatutes of the ancient pin-makers of Paris was, that no mafter fhould open more than one fhop for the fale of his wares, except on new-year's day, and the eve thereof: this we mention in an age of luxury and profufion, to recollect the agreeable fimplicity of our forefathers, who contented themfelves with giving pins for new-year's gifts.

Hence the cuftom of ftill giving the name *pins*, or *pin-money*, to certain prefents, which accompany the moft confiderable bargains; in which it is ufual to give fomething towards the pins of the wife, or children, of the perfon with whom the bargain is ftruck.

Pins, *Hook.* See Hook.

Pins, *Protracting.* See Protracting.

Pin, in *Artillery*, &c. an iron nail or bolt, with a round head, and generally with a hole at the end to receive a key. Of this there are many forts, as axletree-pins, or bolts, bolfter-pins, pole-pins, fwing-tree-pins, &c. Mufket-pins are fmall pieces of iron or wire that faften the ftock.

Pins, *Belaying*, in *Block-making*, are wooden pins, turned in a lathe, made of afh, 16 inches long, and $1\frac{1}{4}$ diameter at the upper end, which is turned as a handle; is $\frac{2}{7}$ths the length, then fhouldered in to $1\frac{1}{4}$ inch diameter.

Pins *of Blocks* are made of lignum-vitæ, or cocus; and fometimes, for common blocks, of green-heart, a wood which is imported from the Weft Indies. The diameter of the pin is the thicknefs of the fheave, and is turned in a lathe, except the head, which is left eight-fquare, to prevent its turning in the block, and is driven through the holes in the block and fheaves. Brafs, iron, and lignum-vitæ fheaves, that are coaked or plated, have iron-turned pins with fquare heads, and fometimes a hole in the point, for a forelock, to prevent their coming out. After the fheaves are fitted, the infide of the fheave-hole, at the arfe of the block, is gouged hollow, to admit the rope, and anfwer with the fheave; and a fmall neat chamfer taken off the edges. See Block.

Pins, in *Ship Building*, are various, according to their feveral purpoſes; ſuch are the bitt-pins, belaying-pins. Pins to prevent the bars of the capſtan unſhipping, are of iron, with an eye and a ſhoulder in their upper end. Connected with the eye is a ſhort chain, fixed to the drum-head: thus they are always ready, when wanted, to put through the ends of bars, when ſhipped.

Pins *of Boats*, are pins of iron or hard wood, fixed along the gunwales of ſome, inſtead of row-locks, whoſe oars are confined by grommets; ſuch are whale-boats, that occaſionally row either end foremoſt. Pins and plates are iron pins, fitted in plates at convenient diſtances in the ſide of the pall-head of capſtans, and occaſionally drawn out to ſupport the palls of the capſtan.

Pin-*Fallow*, in *Agriculture*, a provincial term applied to a winter fallow.

Pin-*Money*, the name given to that allowance uſually made by the huſband to his wife, for her own ſpending.

Ad Pinnas *bibere*, a method of drinking anciently uſed among the Danes in England. The cuſtom was, to fix a pin in the ſide of the wooden cup or waſſal-bowl; which pin each gueſt was to drink bare, upon penalty of forfeiting.

Pin *and Web*, a horny induration of the membranes of the eye, not much unlike a cataract.

The pin and web is the ſame with what we otherwiſe call the pannus, unguis, pterygium, &c.

Pin *Wheel of a Clock*, the ſame with the ſtriking wheel. See Wheel and Clock.

Pin, in *Geography*, a city of China of the ſecond rank, in the province of Chan-tong; 170 miles E.S.E. of Peking. N. lat. 37° 34'. E. long. 117° 40'.

PINA, Ruy de, in *Biography*, one of the earlieſt and beſt Portugueſe hiſtorians, who flouriſhed in the latter part of the 15th and half the 16th centuries. He was employed by Joam II. in many embaſſies of confidence and honour, figned the will of the monarch as public notary, was preſent at his death, and was the perſon who opened and publicly read his will. Emanuel heaped more favours upon him, and made him chief chronicler, an office of which he had already performed the duties. He lived ſome years after the death of this monarch, but the time neither of his birth nor of his death has been aſcertained. He is ſuppoſed to have written the chronicles of Sancho I. and II., Alfonſo II. III. IV. and V., of Diniz and Joam II. Some of theſe are diſputed, and ſaid to be the production of Fernam Lopes. Joam III. commiſſioned him to write the chronicle of his father Emanuel, for which he had collected materials, as the mighty events of that extraordinary reign took place. The celebrated Albuquerque, looking to him as the hiſtorian of his victories, ſent him a preſent of jewels. "He," ſaid his rival, Damian de Goes, "had the ruby rings, and I had the trouble." "Ruy de Pina," ſays Mr. Southey, "might have been called a chronicler of firſt rate merit, if Fernam Lopes had never written, who is infinitely the beſt of all chroniclers. But though coming immediately after that incomparable writer, Ruy de Pina ſtill appears an excellent hiſtorian, and far ſuperior to all who followed him."

PINACIA, Πινακια, among the Athenians, tablets of braſs, whereon the names of all the perſons in each tribe duly qualified, and willing to be judges, or ſenators of the areopagus, being ſeverally written, they were caſt into a veſſel provided on purpoſe; and into another veſſel were caſt the ſame number of beans, a hundred of which were white, and all the reſt black; then the names of the candidates and the beans were drawn, one by one; and thoſe whoſe names were drawn out together with the white beans, were received into the ſenate. See Probuleuma.

In Solon's time there were only four tribes, each of which elected a hundred ſenators; ſo that the areopagus conſiſted of four hundred members; but the number of tribes being afterwards increaſed, the number of ſenators was conſequently augmented by ſome hundreds; but the manner of election remained the ſame. See Areopagus.

PINACLE, La, in *Geography*, a cape on the W. coaſt of the iſland of Jerſey; one mile S. of Grones.

PINACOTHECA, among the *Ancients*, a place where pictures, ſtatues, and other curioſities were kept.

PINAGRA, in *Geography*, a ſtrong mud-fort of Hindooſtan, in Baramaul, taken and deſtroyed by the Britiſh in 1790; 14 miles W.S.W. of Darempour.

PINANG, the name of the kernel of the areca nut, and alſo a preparation made in the Eaſt Indies of this nut, or the mixture of the ingredients which they uſe for maſtication. Into one of the ſiri or betel leaves, a piece of the areca nut, which is generally divided into ſix parts, one of which ſerves at a time, being put, with a little lime, the leaf is folded together, and kept in the mouth till the whole ſtrength is drawn out of it. See Betel.

Pinang, or *Pulo-Pinang*. See Prince *of Wales iſland*.

PINANPIRO, a town of South America, in the province of Quito; 10 miles N.N.E. of Quito.

PINARA, in *Ancient Geography*, a town of Aſia Minor, being one of the largeſt in Lycia. It is placed by Strabo in the interior of this province, at the foot of mount Cragus. —Alſo, a town of Aſia, in the northern part of Cœleſyria, upon the Gindarus, according to Pliny. Ptolemy places it in Pieria of Syria.—Alſo, an iſland of the Ægean ſea, upon the coaſt of Ætolia.

PINARII, among the Romans, an order of prieſts belonging to Hercules, who offered ſacrifices to that god in a ſolemn manner every year. They were in this ſervice connected with the Potitii.

PINARUS, in *Ancient Geography*, a river of Aſia, which roſe in mount Amanus, and purſuing its courſe between two chains of theſe mountains, diſcharged itſelf into the Mediterranean, in the ſtrait where was the bay of Iſſus, in the gulf of Iſſicus.

PINAS, John, in *Biography*, a painter of hiſtory, portrait, and landſcape, born at Haerlem about the year 1596. He travelled to Italy for improvement, and afterwards obtained conſiderable reputation. He had a brother of the name of Jacques, who practiſed in the ſame ſtyle as John, but not with equal ſucceſs.

Pinas, in *Geography*, a town of Spain, in Catalonia; 17 miles N.N.W. of Motril.

Pinas *Iſland*, an iſland on the coaſt of the gulf of Honduras, ſituated off Trivigillo bay.

Pinas *Point*, the eaſtern point of Panama bay. N. lat. 6° 15'. W. long. 80° 30'. The port of this name is on the ſame S.W. coaſt of the iſthmus of Darien, near the point. The whole coaſt ſouthward to cape Corientes abounds with pine-trees, whence the name.

PINASTELLA, in *Botany*, Dill. Giſſ. 168, ſo called by that author from its fancied reſemblance to a pine-tree in miniature. See Hippuris.

PINCH, in *Muſic*, a kind of grace proper for certain inſtruments, particularly the harpſichord; it is formed by ſtriking alternately the ſound of the written note with the ſound of the inferior note, and obſerving to begin and finiſh with the note which bears the pinch. The difference between the pinch and trill is this, that the latter is ſtruck with the ſuperior note, and the pinch with the inferior.

To PINCH, is to ufe the fingers inftead of the bow, to make the chords of an inftrument found. There are fome chord inftruments which have no bow, and which are played only by pinching, as the lute, guitar, &c. and fometimes thofe with which the bow is generally ufed are pinched, as the violin, and violoncello; and this method of playing is marked in the Italian by the word *pizzicato*.

PINCHBECK, in the *Arts*, an alloy of copper and zinc, in various proportions. The copper in all thefe alloys fhould not be in lefs proportion than two of copper to one of zinc. This is fcarcely malleable. The proportions in all cafes fhould be definite. In the inftance of thefe two metals proper compounds will be 1 to 1, 2 to 1, 3 to 1, &c. Any intermediate alloy will be defective. See GOLD-*coloured Metal*.

PINCHE, in *Zoology*, the SIMIA *Oedipus;* which fee.

PINCHES, in *Geography*, a town of South America, in the province of Quito; 100 miles E.S.E. of Macas.

PINCHINA, one of the Cordilleras, in South America.

PINCHING, in *Gardening*, a fort of pruning, performed by nipping or breaking off the branches or fprings of a plant, or tree, between the nails of two fingers.

Moft gardeners hold, that pinching contributes to the abundance of the fruit, as well as of the branches; and they fay that young fhoots, thus lopped, are lefs apt to grow black and die, than when cut with a pruning-knife.

The feafon for pinching is chiefly in April or May; fometimes it is alfo practifed in June and July. The fruits it is practifed on, are chiefly melons, cucumbers, &c. Quintiny alfo prefcribes it for fruit-trees.

It is chiefly to be practifed on the large branches towards the top of the plant, or tree, which are ufelefs, and yet confume a great quantity of good fap. It muft rarely be employed on the large branches below; which ought always to be preferved for the winter's pruning, that they may yield others the following year, fit to fill the empty places. Nor muft the operation of pinching be performed on the tender fhoots; becaufe, having only juft fap enough for themfelves, when they come to put forth more branches in the place where they are pinched, the fmall ftock of fap allotted them, being divided, will ftarve them. The operation is to be performed within two or three eyes of the branch they grow out of.

The effect of pinching is, that inftead of one ufelefs, and, perhaps, hurtful wood-branch, a vigorous tree will put forth two or three at the eyes remaining; and the fap being thus divided, the branches will be lefs, and fit for both wood and fruit.

PINCHING, in the *Manege*, is when, the horfe ftanding, the rider holds him faft with the bridle-hand, and applies the fpurs juft to the hairs of his fides, without pricking him.

If the horfe is impatient under this, and draws himfelf up, and wants to go forward, it is a fign of vigour and mettle. But the purchafer ought to try the thing himfelf on the horfe's back; for the jockies have the art of making the dulleft horfe feem to have mettle in thefe trials. The purchafer muft alfo diftinguifh between the reftleffnefs of the horfe under this treatment that arifes from vigour, and that which arifes from the horfe's being ticklifh, and which goes off immediately.

Pinching is accounted an aid, fpurring a chaftifement or correction.

PINCHUGA, in *Geography*, a town of Ruffia, in the government of Tobolfk. N. lat. 58° 20'. E. long. 96° 54'.

PINCKNEY, an ifland on the coaft of South Carolina.—Alfo, a diftrict, formerly of the upper country of South Carolina, now divided into the diftricts of York, Chefter, Union, and Spartanburgh.

PINCKNEYA, in *Botany*, fo named by Michaux, (we are not refponfible for the orthography,) in honour of one of his friends or patrons in America, probably Mr. Pinkney, once envoy to the Britifh court; but nothing is recorded on the fubject, either in the Flora of Michaux, or in the account of his life, where this tree is mentioned, (fee Sims and Konig's Ann. of Bot. v. 1. 333,) as ufed by the inhabitants of Georgia to cure fevers, being allied to the *Cinchona*, or Peruvian bark. Michaux Boreal-Amer. v. 1. 103. Ait. Hort. Kew. v. 1. 372. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juff.

Gen. Ch. *Cal.* Perianth fuperior, in five deep acute fegments, one (rarely two) of which is dilated into a large coloured leaf, deciduous. *Cor.* of one petal, funnel-fhaped; tube thrice as long as the ordinary fegments of the calyx, five-fided; limb in five deep, revolute, obtufe, nearly equal fegments, half the length of the tube. *Stam.* Filaments five, awl-fhaped, equal, inferted into the tube near its bafe, fhorter than the limb; anthers oblong, incumbent. *Pift.* Germen inferior, roundifh-oblong; ftyle the length and form of the ftamens; ftigma thickifh, in two obtufe lobes. *Peric.* Capfule globofe, flightly compreffed, with a furrow at each fide, cartilaginous, thin, coated, of two cells and two valves, the partitions from the centre of each valve. *Seeds* numerous, horizontal, oval, depreffed, with a membranous orbicular wing. *Receptacle* central, angular.

Eff. Ch. One fegment of the calyx very large, leafy. Corolla funnel-fhaped, five-cleft. Stamens prominent. Stigma bluntly two-lobed. Capfule inferior, of two cells and two valves. Seeds numerous, winged.

1. P. *pubens.* Downy Pinckneya. Mich. ibid. 105. t. 13.—Native of the banks of the river St. Mary in Georgia. Brought into England by the late Mr. John Frafer in 1786. It is a greenhoufe plant, flowering in June and July. We are obliged to Mr. Frafer for fine fpecimens in flower and feed. Others are found in the herbarium of the younger Linnæus, which muft have been collected before Michaux vifited America, and we fufpect they were fent by Bartram. This is a very handfome *fhrub*, or fmall *tree*, with oppofite downy *branches*. *Leaves* oppofite, on downy ftalks, oval, acute at each end, entire, a fpan long; naked, but roughifh above; paler and rather downy beneath. *Stipulas* between the footftalks, fmall, acute, deciduous. *Panicles* terminal, corymbofe, many-flowered, downy, as well as the *calyx*, and outfide of the *corolla*. *Flowers* an inch long, pale, ftreaked with purple. Their moft confpicuous part is the large, oval, whitifh, downy, leafy expanfion, which takes the place of one fegment of the *calyx*, as in the firft and fecond fpecies of MUSSÆNDA; fee that article. The *capfule* is as big as a large goofeberry, of a rigid, cartilaginous, but thin texture, with a deciduous fkin. This genus is intermediate between *Cinchona* and *Muffænda*, but feems fufficiently diftinct in its fruit from the former; as it unqueftionably is from the latter, with which the habit moft agrees. The name of *Bartramia* was deftined for it, the original *Bartramia* being a *Triumfetta;* but there is now a very fine and diftinct genus of moffes eftablifhed under this appellation. See MUSCI.

PINCKNEYVILLE, in *Geography*, a poft-town of South Carolina, and capital of Union diftrict, on the S.W. fide of Broad river, at the mouth of Pacolet, containing a handfome work-houfe, a gaol, and a few compact houfes; 75 miles N.W. of Columbia.

PINCOS,

PINCOS, a town of Peru, in the diocefe of Lima; 15 miles S. of Xauxa.

PINCZESTI, a town of European Turkey, in Moldavia; 28 miles S.W. of Jaffy.

PINDA, a fea-port town of Africa, in the kingdom of Congo, on the left fide of the Zaire; 125 miles W.S.W. of St. Salvador.—Alfo, a river of Africa, which runs into the Indian fea, S. lat. 13° 28′.

PINDALA, a town of Hindooftan, in Tellingana; 15 miles S. of Warengole.

PINDAMAHA, a town of Brafil, in the government of St. Paul; 80 miles N.N.E. of St. Paul.

PINDAR, in *Biography*, the moft famous lyric poet of ancient Greece, was a native of Cynofcephalæ, near Thebes in Bœotia. The time of his birth is uncertain, but it is well known that he was at the height of his reputation at the time of the expedition of Xerxes, or B.C. 480. Although brought up under excellent inftructors, he was chiefly indebted to his own exertions and genius for his peculiar excellencies. His chief patrons were Theron of Agrigentum and Hiero of Syracufe, whom he has commemorated in his poems. He celebrated the city of Athens in fuch lofty terms, as greatly to excite the difpleafure of his countrymen the Thebans, who, on that account, impofed a fine upon him, which the Athenians not only doubly repaid, but erected a ftatue to his honour. His reputation was fo great, that we find he was rewarded in the public affemblies of Greece with the prize, in preference to every other competitor; and as the conquerors at Olympia were the fubjects of his compofitions, the poet was courted by ftatefmen and princes. His hymns and pæans were repeated before the moft crowded affemblies in the temples of Greece; and the prieftefs of Delphi declared that it was the will of Apollo that her chief poet fhould receive half of all the firft-fruit offerings that were annually heaped on his altars. This was not the only public honour which he received; after his death he was honoured with every mark of refpect, even to adoration. His ftatue was erected at Thebes in the public place where the games were exhibited, and, fix centuries after, it was viewed with the utmoft fenfations of pleafure and admiration by the geographer Paufanias. The honours which were paid him while alive were alfo fhared by his pofterity, and as a mark of their high attention and reverence, at the celebration of one of the feftivals of the Greeks, a portion of the victim which had been offered in facrifice was referved for the defcendants of the poet. Even the moft inveterate enemies of the Thebans fhewed a regard for his memory, and the Spartans fpared the houfe which the prince of the Lyrics had inhabited, when they deftroyed the houfes and the walls of Thebes. The fame fort of refpect was likewife paid him by Alexander the Great, when Thebes was reduced to afhes. He died in the public theatre at an advanced age, about the year 440 B.C. The greateft part of his works has perifhed. He had compofed fome hymns to the gods, poems in honour of Apollo, dithyrambics to Bacchus, and odes on feveral victories obtained at the four greateft feftivals of the Greeks, the Olympic, Ifthmian, Pythian, and Nemean games. Of all thefe the odes are the only compofitions extant, admired for fublimity of fentiments, grandeur of expreffion, energy and magnificence of ftyle, boldnefs of metaphors, harmony of numbers, and elegance of diction. In thefe odes, which were repeated with the aid of mufical inftruments, and accompanied by the various inflections of the voice, with fuitable attitudes, and proper motions of the body, the poet has not merely celebrated the place where the victory was won, but has introduced beautiful epifodes, and by unfolding the greatnefs of his heroes, the dignity of their characters, and the glory of the feveral republics where they flourifhed, he has rendered the whole highly beautiful, and in the greateft degree interefting. Horace has called our poet inimitable, and this panegyric will not, perhaps, appear too ftrong, fince fucceeding critics have agreed in extolling his beauties, his excellence, the fire, the animation and enthufiafm of his genius. Horace refers likewife to his pathetic and moral commemorations of departed excellence. It was probably in ftrains of this kind by which he acquired the epithets of *wife* and *divine* from Plato. Dionyfius of Halicarnaffus fpeaks of Pindar as the chief model among the lyric poets of what he denominates "fevere and antique harmony," and he alfo extols his loftinefs, energy, fertility, art, and ftrength of diction mixed with fweetnefs. Quintilian repeats thefe praifes, but Longinus reprefents him as fometimes, when glowing with the brighteft flame, undergoing a fudden extinction; and a more modern critic feems to join iffue with the author of the "Sublime:" fpeaking of his odes, he fays they have indeed thofe characteriftics of fire, rapidity, and variety, for which he is fo much celebrated by the critics of antiquity, but that fire is frequently obfcured in fmoke, and that variety is produced by digreffions fo excurfive, that it is often fcarcely poffible to follow him, and trace their relation to his propofed fubject." The beft editions of this poet are thofe of Heyne, Gr. et Lat. Gotting. 1773, 1798; the latter, which is in octavo, contains the Greek fcholia. Moreri. Bibliogr. Dict.

PINDARIC, in *Poetry*, an ode formed in imitation of the manner of Pindar.

The Pindaric manner is diftinguifhed by the boldnefs and height of the flights, the fuddennefs and furprifingnefs of the tranfitions, and the feeming irregularity, wildnefs, and enthufiafm, of the whole.

Pindar, whence the manner takes its name, was of Thebes: he flourifhed about four hundred and fixty-eight years before Chrift, and was contemporary with Æfchylus. What we have remaining of his is a book of odes, all in praife of the victors at the Olympian, Pythian, Nemæan, and Ifthmian games; whence the firft is entitled, the *Olympians;* the fecond, the *Pythians;* the third, the *Nemæans;* and the fourth, the *Ifthmians.* Pindar is full of force and fire; his thoughts are fententious, his ftyle impetuous, his fallies daring, and frequently running, as it were, at random; he affects a beautiful diforder, which, yet, is faid to be the effect of the greateft art. See the preceding article.

As the fubject which engaged his attention comprehended the praifes of thofe who had gained the prize in the public games, it was neceffarily very barren; and therefore he is perpetually digreffive, and fills up his poems with fables of the gods and heroes, that have little connection either with his fubject or with one another. Many of the hiftories of particular families and cities, to which he alludes, are now unknown to us, and therefore, though the ancients admired him greatly, he is often fo obfcure to modern readers, partly from his fubjects, and partly from his rapid abrupt manner of treating them, that, notwithftanding the beauty of his expreffion, our pleafure in reading him is very much diminifhed.

The fuppofed irregularity of his numbers has made feveral of his imitators imagine themfelves Pindaric poets, by the mere wildnefs and irregularity of their verfes. None of our writers feem to have fucceeded in the Pindaric character better than Cowley.

In a Pindaric ode, the plan of the whole ought to be drawn firft, and the places marked out where the elegant fallies

fallies and wanderings may beft be, and how the returns may be juftly made to the fubject. See Ode.

PINDING, a difeafe among lambs which are in the ftate of fuckling. Thefe animals, before they begin to eat grafs, are liable to have a difcharge from the bowels of a tough, glutinous, adhefive quality, which is apt to ftick to the tail and buttocks, and when hardened by the fun, fometimes to glue them together in fo clofe and firm a manner, as to prevent all poffibility of their having any evacuations, and thereby foon to mortify and burft the inteftines. The complaint is difcovered in an eafy manner, by the lambs appearing fwelled and fick, with the upper and middle parts of their tails clofely glued down, and they are as readily cured, by feparating their tails from their buttocks, when the retained excrement will be difcharged with a difagreeable fmell. And the immediate recurrence of it will be prevented by rubbing the parts over with fand, friable clay, mud, or, what is better, a little tallow. But they muft be well looked after for eight or ten days, until they begin to eat grafs, when all danger from thefe obftructions is over. It is faid to be moft dangerous when the ewes are in high condition, and the feafon dry and backward; and feldom or ever to appear when the mothers are lean, and the weather difpofed to be wet.

PINDLOCK, in *Geography*, a town of Germany, in the principality of Culmbach; three miles N.N.E. of Bayreuth.

PINDMISSUS, in *Ancient Geography*, a town of Afia, in Syria, fituated on the mountains, near the fmall river Singas, on the W. fide of the Euphrates, S.W. of Samofata.—Alfo, a town of Cilicia, near mount Amanus, belonging to the Eleuthero-Cilicians, according to Cicero, ad Attic. l. v.

PINDUS, a chain of mountains of Theffaly, extending to the S.W., confecrated to the Mufes. This chain extended alfo towards Epirus, and was inhabited by the Atthamanes, the Æthices, and the Perrhæbians.—Alfo, a town of Greece, in the Doride, placed by Strabo on the banks of a river of the fame name, which difcharged itfelf into the Cephifus. It is alfo called "Ciphus" by fome authors. It was within the territory of this town that the Hellenes, driven from the Hifteiotide by the Cadmæans, went to eftablifh themfelves, according to Herodotus.

PINE, in *Botany*, &c. See Bromelia and Pinus.

Pine, in the *Materia Medica* and *Rural Economy*. Although moft fpecies of fir poffefs in common the fame medicinal properties, and all agree in affording the different products of the turpentine kind, yet fome fpecies produce thefe different articles in greater purity, and in more abundance, than others. From the wild pine, Pinus fylveftris, pinafter, or Scotch fir-tree, is obtained moft plentifully the pix liquida, or tar, and from it may alfo be procured the common turpentine, and the white and yellow refins. The manner in which the tar is procured is by cutting the tree into pieces, and then enclofing them in a large oven conftructed for the purpofe, with a channel at the bottom. A fufficient degree of heat is then applied, by which the tar is forced out of the wood, and it runs off by the opening at the bottom: a procefs which is denominated "diftillatio per defcenfum."

Upon an incifion being made into the bark of the Pinus abies, or Norway fpruce fir-tree, a clear tenacious fluid iffues, which concretes into a refinous fubftance, known by the name of "refina abietis." This, after being boiled in water, and ftrained through a linen cloth, is called in the Pharmacopeias "pix Burgundica," or Burgundy pitch. But if the boiling of the native refin is continued till the water is wholly evaporated, and wine vinegar is at this time added, a fubftance is formed, called "colophonium;" which fee. See alfo *Burgundy* Pitch.

Linnæus, and feveral other writers in the Materia Medica, refer the common turpentine to the "pinus fylveftris;" and the "Terebinthina argentoratenfis," or Strafburgh turpentine, to the "Pinus picea," or filver fir-tree; yet upon the authority of Murray, who follows Du Hamel and Haller, Dr. Woodville afcribes the "Terebinthina vulgaris" to the latter pine, which pours out the turpentine fo freely, that it is feldom neceffary to make incifions through the bark for the purpofe.

The "Terebinthina Veneta," or "larigna," as it may be more properly called, (becaufe we are not wholly fupplied with this article by the Venetians,) iffues fpontaneoufly through the bark of this tree, but is more commonly obtained by wounding the bark at the diftance of about two feet from the ground, and inferting in the wood a fmall cannula, through which the turpentine flows into proper veffels, which are placed for its reception.

We may here obferve farther, and more generally, that pitch, tar, refin, and turpentine, are all made from thefe trees by a very familiar procefs. In the fpring time, when the fap is moft free in running, they pare off the bark of the pine-tree, to make the fap run down into a hole, which they cut at the bottom to receive it; in the way, as it runs down, it leaves a white matter like cream, but a little thicker; this is very different from all the kinds of refin and turpentine in ufe, and it is generally fold to be ufed in the making of flambeaux, inftead of white bees-wax. The matter that is received in the hole at the bottom is taken up with ladles, and put into a large bafket; a great part of this immediately runs through, and this is the common turpentine. This is received into ftone or earthen pots, and is ready for fale. The thicker matter, which remains in the bafket, they put into a common alembic, and adding a large quantity of water, they diftil this fo long as any oil is feen fwimming upon the water; this oil they feparate from the furface in large quantities, and this is the common oil or fpirit of turpentine: the remaining matter at the bottom of the ftill is common yellow refin. When they have thus obtained all that they can from the fap of the tree, they cut it down, and hewing the wood into billets, they fill a pit dug in the earth with thefe billets; and fetting them on fire, there runs from them, while they are burning, a black thick matter; this naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out of which the tar runs like oil; if this hole be made too large, it fets the whole quantity of the tar on fire; but if fmall enough, it runs quietly out.

The tar, being thus made, is put into barrels; and if it be to be made into pitch, they put it into large boiling veffels, without adding any thing to it; it is then fuffered to boil a while, and being then let out, is found, when cold, to be what we call pitch. Phil. Tranf. N° 243. p. 291.

In a medical point of view it may be remarked, that the kernels of the nuts of the manured or ftone pine, are of a balfamic and nourifhing nature; good for confumptions, coughs, and hoarfenefs, reftorative, and of fervice after long illnefs.

The leaves and tender tops of pines and fir are ufed for diet-drinks, and allowed to be antifcorbutic and diuretic See Chowder-*beer*.

The refinous exudations of pines or firs are an important branch in the materia medica, and not only ufeful in the prefcriptions of phyficians, but have alfo been thought otherwife wiſe conducive to health. Pliny tells us, that wines, in the time of the old Romans, were medicated with pitch and reſin. And Jonſtonus, in his Dendrographia, obſerves, that it is wholeſome to walk in groves of pine-trees, which impregnate the air with balſamic particles. It is known that all turpentines and reſins are good for the lungs, againſt gravel, alſo, and obſtructions; and it is ſaid, that the medicinal properties of thoſe drugs are found in tar-water, which operates without heating the blood, or diſordering the ſtomach. See PITCH, RESIN, TAR, and TURPENTINE.

PINE-*Apple*, in *Botany*, *Gardening*, &c. See BROMELIA.

PINE, *Ground*, a ſpecies of germander.

PINE, *Heath*, *Low*. See CORIS.

PINE, *Screw*. See PANDANUS.

PINE, *Stinking ground*. See CAMPHOROSMA.

PINE-*Tree*, in *Planting*, the name of a foreſt tree, of which there are ſeveral kinds that deſerve cultivating; namely, the Scotch pine, which is ſo called from its growing naturally on the mountains in Scotland, and which is the tree that affords the red or yellow deal, which is the moſt durable of any of the kinds yet known. The leaves of this tree are pretty broad and ſhort, of a greyiſh colour, growing two out of each ſheath; the cones are ſmall, pyramidal, and end in narrow points; they are of a light colour, and the ſeeds are ſmall: this ſort grows well upon almoſt every ſoil; they have been planted in great numbers upon peat-bogs, where they have made great progreſs; alſo in clay ſoils, where they have ſucceeded far beyond expectation; and upon ſand, gravel, and chalk, they likewiſe thrive well; but as they do not grow near ſo faſt upon gravel and ſand as upon moiſt ground, ſo the wood is much preferable; for thoſe trees which have been cut down upon moiſt ſoils, where they have made the greateſt progreſs, when they have been ſawn out into boards have not been valuable; the wood has been white, and of a looſe texture; whereas, thoſe which have been grown upon dry gravelly ground, have proved nearly equal to the beſt foreign deals. Thoſe plantations, which have been made of late years of theſe trees, will in the next age, not only turn greatly to the advantage of their poſſeſſors, but alſo become a national benefit.

Another variety of this ſort of tree is called *pineaſter*, which is a large timber tree, and naturally throws out very large arms, ſome of which will be nearly horizontal. Some people think theſe trees very ornamental on this account; for, in the winter eſpecially, they appear naked, and are of a yellowiſh colour; and being ſpread abroad thus large, and without order, in the mixture of the more regular ſorts of growing firs, they make a good contraſt. It muſt be obſerved, that the leaves of this ſort are very large and long, and of a lighter green, than thoſe of the Scotch fir, which is another circumſtance to direct to its ſituation; and it muſt alſo be obſerved, that thoſe long and large leaves which ornament the younger branches only, give the tree a majeſtic air; and as the larger arms appear naked to view, ſo the younger, being thus plentifully furniſhed, have a noble effect, beſides what beauty it receives from its numerous cones. And Mr. Nicol remarks, that the timber of the Scotch pine or fir is found in higheſt perfection on the bleak and gravelly ſcites. In light ſand, it is alſo found durable. But in the richer more loamy ſoils, although it grows apace while young, and flouriſhes exuberantly, it ſoon ſickens, is ſhort-lived; nor is the wood valuable, but ſhort and brittle. On retentive, tilly clays, in which it is often planted, but from which, above all others, it ſhould be excluded, it frequently becomes ſtinted about the twentieth or thirtieth year of its age; or when the roots have exhauſted the upper ſoil, and begin to ſeek paſturage in the ſub-ſoil, inſomuch, that the worms attack it on its limbs, anticipating, as it were, its diſſolution.

And the white, or Weymouth pine, is one of the talleſt trees of all the ſpecies, often growing a hundred feet high. The bark of this tree is very ſmooth and delicate, eſpecially when young; the leaves are long and ſlender, five growing out of each ſheath; the branches are pretty cloſe, garniſhed with them, ſo make a fine appearance; the cones are long, ſlender, and very looſe, opening with the firſt warmth of the ſpring: ſo that if they are not gathered in winter, the ſcales open and let out the ſeeds. The wood of this ſort is eſteemed for making of maſts for ſhips. As the wood of this tree was generally thought of great ſervice to the navy, there was a law made in the ninth year of queen Anne, for the preſervation of the trees, and to encourage their growth in America: and it is only within theſe forty years paſt that theſe trees have begun to be propagated in England in any plenty, though there were ſome large trees of this ſort growing in two or three places long before, particularly at the marquis of Bath's at Longleet; and ſir Wyndham Knatchbull's in Kent; and it hath been chiefly from the ſeeds of the latter that the much greater number of theſe trees now in England have been raiſed; for although there have annually been ſome of the ſeeds brought from America, yet thoſe have been few in compariſon to the produce of the trees in Kent: many of the trees which have been raiſed from the ſeeds of thoſe trees, now produce plenty of the ſeeds, particularly thoſe in the garden of the late duke of Argyle at Whitton, which annually produce large quantities of cones.

According to Hanbury, the ſoil which this tree delights in moſt is a ſandy loam; but it likes other ſoils of an inferior nature; and although it is not generally to be planted on all lands, like the Scotch fir, yet he has ſeen it luxuriant and healthy, making ſtrong ſhoots, on blue and red clays, and other ſorts of ground; on ſtrong and ſlaty ground, likewiſe, he has ſeen ſome very fine trees: ſo that, he believes, whoever is deſirous of having plantations of this pine, need not be curious in the choice of his ground.

And this ſort of pine will grow, Mr. Nicol ſays, in many different ſoils and ſituations, but ſeems to affect moſt a deep ſandy loam. On chalky, gravelly, elevated grounds, it is found to luxuriate. It will alſo thrive in pretty ſtrong clay, if lying on an open ſub-ſtratum. It is impatient of ſtagnant water, nor will it flouriſh on a till. It is an elegant tree, and worthy of a place in all extenſive plantations. He conſiders the timber as much ſuperior in quality when produced on mountains, to that produced on richer ſoils, and in more ſheltered ſituations. In fine, as already ſaid, except on ſandy or gravelly ſoils, this tree ought not to be planted. The many obſervations he has made in the Highlands confirm him in this opinion. The value of fir-timber (and that reared in the northern parts of the iſland, in ſoil and ſituation as above, is inferior to none) is known to every mechanic; nor is there any one at all acquainted with the arts, who does not know, that from this tree is extracted roſin, tar, &c.: articles which are ſo uſeful for many, eſpecially naval purpoſes.

And the deciduous pine or larch is a lofty tree: its branches are ſlender, and incline downward: the leaves are of a light green; and like thoſe of the cedar, are bunched together in a ſimilar manner to the pencils or little bruſhes of the painter. In ſpring, when the leaves and flowers are breaking out, it has a particularly elegant appearance; and in the winter, it gives variety to a wooded ſcene by the bright colours of its naked branches: it is in good eſteem as an ornamental tree, and its timber is of the more uſeful kind, being ſuperior to that of moſt of the pine tribe. Indeed the utility of its wood has been highly extolled by ancient writers, and there can be no doubt but that it is an excellent wood for ſhip and houſe building. At Venice its wood is frequently uſed in building their houſes, as well as in Switzerland, where thoſe trees abound: ſo that, without doubt, the larch excels for maſts for ſhips, or beams for houſes, doors, windows, &c. particularly as it is ſaid to reſiſt the worm. It is remarked, that in Switzerland their houſes are covered with boards of this wood, cut out a foot ſquare; and as it emits a reſinous ſubſtance, it ſo diffuſes itſelf into every joint and crevice, and becomes ſo compact and cloſe, as well as ſo hardened by the air, as to render the covering proof againſt all weather. But as ſuch coverings for houſes would cauſe great devaſtation in caſe of fire, the buildings are confined to a limited diſtance by an order of police from the magiſtrates. The wood, when firſt laid on the houſes, is ſaid to be very white; but this colour, in two or three years, is changed, by means of the ſun and reſin, to a black, which appears like a ſmooth ſhining varniſh.

In his work on planting, Mr. Marſhall has obſerved, that of the common larch there are ſeveral varieties. And that the flowers which the commoneſt ſort exhibits early in the ſpring are of a delicate red colour; another ſort produces white flowers at the ſame ſeaſon, and theſe have a delightful effect among thoſe of the red ſort; whilſt another, called the black Newfoundland larch, increaſes the variety, though by an aſpect little differing from the others. There are alſo larches with greeniſh flowers, pale-red, &c. all of which are accidental varieties from ſeeds. Theſe varieties are eaſily diſtinguiſhed, even when out of blow: the young ſhoots of the white flowering larch are of the lighteſt green, and the cones when ripe are nearly white. The red-flowering larch has its ſhoots of a reddiſh caſt, and the cones are of a brown colour; whilſt the cones and ſhoots of the black Newfoundland larch are in the ſame manner proportionably tinged. The cones, which are a very great ornament to ſeveral ſorts of the pines, are very little to theſe. Their chief beauty conſiſts in the manner of their growth, the nature and beauty of their pencilled leaves, and fair flowers; for the cones that ſucceed them are ſmall, of a whitiſh, a reddiſh, or a blackiſh-brown colour, and make no figure.

It is ſtated by the ſame writer, that the larch tree will grow extremely well on almoſt any ſoil, as well in clays as in other ſorts; it thrives amazingly on the declivities of hills, and ſides of high mountains; it is hardy enough to reſiſt the ſevereſt cold, therefore proper for all expoſed places: and, as the timber is ſo valuable, and its growth ſo quick, it is a tree which may be propagated to the great advantage of the owner. In fact, it is almoſt impoſſible to ſay too much in favour of this tree. It grows on the barreneſt ſoils, and in the bleakeſt ſituations. In rich genial ſcites it luxuriates too much, grows top-heavy, and either loſes its head, or is bowed down into an unſightly form, and becomes unprofitable. Its timber, whether in the water, or in contact with the earth, is durable almoſt beyond compariſon.

In his Treatiſe on Planting, Mr. Nicol, however, obſerves that, which ſoil, in this country, when in a ſtate of full maturity, this noble tree may moſt affect, remains yet to be known. If we may judge from appearances, we ſhall decide, that it will be found in the higheſt perfection of timber in the lighter more gravelly ſoils, and in elevated ſituations. That it luxuriates beyond every other tree, in all ſoils and ſituations, excepting thoſe of a low, humid kind, is demonſtrated in every inſtance where impartial compariſon is made.

And it is obſerved by Marſhall, that the Norway ſpruce is a tree of as much beauty while growing, as its timber is valuable when propagated on that account. Its growth is naturally like the ſilver fir upright; and the height it will aſpire to may eaſily be conceived, when we ſay that the white deal, ſo much coveted by the joiners, &c. is the wood of this tree; and it may perhaps ſatisfy the curious reader to know that from this fir pitch is drawn. The leaves are of a dark green colour; they ſtand ſingly on the branches, but the younger ſhoots are very cloſely garniſhed with them. They are very narrow, their ends are pointed, and they are poſſeſſed of ſuch beauties as to excite admiration. The cones are eight or ten inches long, and hung downwards.

The better the ſoil is, the faſter will the ſpruce fir grow, though it will thrive very well in moſt of our Engliſh lands. In ſtrong loamy earth it makes a ſurpriſing progreſs; and it delights in freſh lands of all ſorts, which never has been worn out by ploughing, &c. though it be ever ſo poor.

But why this tree has obtained the name of Norway, rather than Swediſh or Daniſh ſpruce, is a queſtion Mr. Nicol thinks of little importance. Certain it is, however, that many have been led to miſtake on this account, ſuppoſing it to be the tree which produces the deal known by the name of Norway fir, and which is the produce of the Scotch fir beyond all doubt. The timber known by the name of Memel log is the produce of the ſpruce. It will, he adds, like all the fir tribes, grow in very different ſoils; but it is found in greateſt luxuriance in deep ſandy loams, where it hath freedom of ſpace. On clays which are not retentive of water below, although moiſt of themſelves, it will make ſurpriſing progreſs. On thin ſoils, and in bleak ſituations, it grows ſlowly; and may therefore become the better timber of any, on ſuch: but here it becomes unſightly.

It cannot be cultivated in this country with ſuch advantage as the Scotch fir, in reſpect of timber; but as an ornamental tree it outdoes it, where the ſoil is favourable. There are ſome majeſtic ſpruce firs at Duplin, the ſeat of lord Kinnoul, which are ſuppoſed the largeſt in the kingdom. From this tree pitch is alſo extracted in great abundance.

The American ſpruce fir, Mr. Marſhall thinks, includes three varieties: the white Newfoundland ſpruce; the red Newfoundland ſpruce; and the black Newfoundland ſpruce; they however differ ſo little, that one deſcription is common to them all. They are of a genteel upright growth, though they do not ſhoot ſo freely or grow ſo faſt with us as the Norway ſpruce. The leaves are of the ſame green, and garniſh the branches in the ſame beautiful manner as thoſe of that ſpecies, only they are narrower, ſhorter, and ſtand cloſer. The greateſt difference is obſervable in the cones; for theſe are no more than about an inch in length, and the ſcales are cloſely placed. In the cones, indeed, conſiſts the difference of theſe three ſorts: thoſe of the white ſpecies are of a very light brown colour; thoſe of the red ſpecies more of a nut brown or reddiſh colour; and thoſe of the black ſpecies of a dark or blackiſh colour. Beſides this, there is ſcarcely any material difference; though it is obſervable, that this trifling variation ſeems to be pretty conſtant in the plants raiſed from the like ſeeds. Theſe ſorts will often flower and produce cones when only about five or ſix feet high; and indeed look then very beautiful: but this is a ſign of weakneſs in the plant, which it does not often fairly overcome. And it is added, that in many parts of England this is a very difficult tree to raiſe. It ſpends itſelf in cones, and becomes ſtunted and unſightly. Nevertheleſs, in the vallies of the Highlands, it thrives with full luxuriance and vigour; forming a rich picturable outline, poſſeſſing more ſtrength of feature than moſt of the pines. As a ſtandard in poliſhed ſcenery, there are few trees that equal it; as may be ſeen at Enville and Fiſherwick.

But Mr. Nicol thinks that theſe trees ſeem to affect moſt a deep black loam of a middling texture, and which is alſo ſub-humid of itſelf, but does not retain ſtagnant water. They will alſo thrive well on ſandy or gravelly loams of a moiſt nature. On dry ſhallow ſoils they languiſh; nor will they thrive on very expoſed ſcites. In deep, ſub-humid vallies, are to be found thoſe moſt ſtately in this country. They require full ſpace; otherwiſe they become very unſightly, even in youth. This tree, in America, arrives to great magnitude, and produces that vaſt ſtore of maſts and ſpars exported thence to Europe. Of this tree they alſo conſtruct many ſhips of great burthen. But, in this country, the larch far excels it in any ſituation, and, as timber, is more valuable for this and all other purpoſes.

It becomes a fine ornamental detached tree on good ſoil, if allowed room to branch in its youth, and while nurſing; but at the ſame time it requires ſhelter.

There are two varieties of the yellow-leaved fir, of which the ſilver fir is a noble, upright, full-growing tree. The branches are not very numerous, and the bark is ſmooth and delicate. The leaves grow ſingly on the branches, and their ends are ſlightly indented. Their upper ſurface is of a fine ſtrong green colour, and their under has an ornament of two white lines, running lengthways on each ſide the midrib, on account of which ſilvery look this ſort is called the ſilver fir. The cones are large, and grow erect; and when the warm weather comes on, they ſoon ſhed their ſeeds; which ſhould be a caution to all who wiſh to raiſe this plant, to gather the cones before that happens.

The other variety is the balm of Gilead fir, which has of all the ſorts been moſt coveted, on account of the great fragrance of its leaves: though this is not its only good property; for it is a very beautiful tree, naturally of an upright growth, and the branches are ſo ornamented with their balmy leaves, as to exceed any of the other ſorts in beauty. The leaves, which are very cloſely ſet on the branches, are broad, and their ends are indented. Their upper ſurface, when healthy, is of a fine dark green colour, and their under has white lines on each ſide the midrib lengthways, nearly like thoſe of the ſilver fir. Theſe leaves, when bruiſed, are very finely ſcented; and the buds, which ſwell in the autumn for the next year's ſhoot, are very ornamental all winter, being turgid, and of a fine brown colour; and from theſe alſo exudes a kind of fine turpentine, of the ſame kind of (though heightened) fragrancy.

The ſilver fir is exceedingly hardy, and will grow in any ſoil or ſituation, but always makes the greateſt progreſs in a good rich loamy earth.

Mr. Nicol remarks, that the ſilver fir grows moſt luxuriantly in deep loamy earth; but there its wood is ſoft and ſpongy. It will thrive on bleak expoſures, and thin gravelly or ſandy ſoil. But that in which we may expect its timber in higheſt perfection, is a ſandy loam, lying on a gravelly ſubſoil, or dry rock. On the mountains of Switzerland it is ſaid to grow to a vaſt ſize, is excellent timber, and is uſed for many valuable purpoſes. In particular, turpentine is extracted from it; and it would ſeem that from this tree is extracted the true Venice turpentine; although there is an inferior kind extracted from the larch, which alſo paſſes under that name. As an ornamental tree, it is admiſſible in all extenſive deſigns, and even on a ſmaller ſcale where variety is ſtudied.

The latter ſort muſt be planted in a deep, rich, good earth; neither will it live long in any other ſort of ſoil. It matters little whether it be a black mould, or of a ſandy nature, provided it be deep, and there is room for the roots to ſtrike freely. See Pinus.

In the raiſing of the trees, all the ſorts are propagated by ſeeds, which are produced in their hard woody cones: the way to get the ſeeds out of theſe cones, which are cloſe, is to lay them in the ſun or before a gentle fire, which cauſes the cells to open, and then the ſeeds may be eaſily taken out. If the cones are kept entire, the ſeeds will remain good ſome years, ſo that the ſureſt way to preſerve them, is to let them remain in the cones until the time of ſowing: if the cones are kept in a warm place in ſummer, they will open and emit the ſeeds; but if they are not expoſed too much to heat, many of the ſorts will remain entire ſome years, eſpecially thoſe which are cloſe and compact; and the ſeeds, which have been taken out of cones after ſeven years, have grown very well, ſo that theſe may be tranſported to any diſtance, provided the cones are well ripened and properly put up.

The beſt time for ſowing the ſeeds is about the end of March; when they are ſown, the place ſhould be covered with nets to keep off birds: otherwiſe, when the plants begin to appear with the huſk of the ſeed on their tops, the birds will pick off the heads of the plants, and deſtroy them. Where the quantity of ſeed to be ſown is large, ſo as to require a good ſpace to receive them, they ſhould be ſown on an eaſt or north-eaſt bed of fine mould in the nurſery, where they may be ſcreened from the ſun, whoſe heat is very injurious to the plants at their firſt appearance above ground. When the plants appear, they muſt be conſtantly kept clean from weeds; and in very dry ſeaſons, if they are now and then gently refreſhed with water, it will forward their growth; but this muſt be done with great care and caution, for if they are haſtily watered it may waſh the tender plants out of the ground, or lay them down flat, which often rots their ſhanks; and when this is too often repeated, it will have the ſame effect; ſo that unleſs it is judiciouſly performed, it will be the beſt way to give them none, but only ſcreen them from the ſun and wind.

In caſes where the plants come up too cloſe, it will be a good method to thin them gently about the beginning of July. The plants, which are drawn up may be planted on other beds, which ſhould be prepared ready to receive them, as they ſhould be immediately planted as they are drawn up, becauſe their tender roots are ſoon dried and ſpoiled at this ſeaſon of the year. This work ſhould be done, if poſſible, in cloudy or rainy weather, and then the plants will draw out with better roots, and will ſoon put out new fibres again; but if the weather ſhould be dry, the plants ſhould be ſhaded every day from the ſun with mats, and now and then gently refreſhed with water. In drawing up the plants, there ſhould be great care taken not to diſturb the roots of thoſe that are left remaining in the ſeed-beds, &c. ſo that if the ground be hard, the beds ſhould be well watered ſome time before the plants are thinned, to ſoften and looſen the earth; and if, after they are drawn out, the beds are again gently watered to ſettle the earth to the roots of the remaining plants, it will be of great ſervice to them; but it muſt be done with great care, ſo as not to waſh out their roots, or lay down the plants. The diſtance which ſhould be allowed theſe plants, is four or five inches row from row, and three inches in the rows, but ſome allow them more.

And in theſe beds the plants may remain till the ſpring twelve-months after, by which time they will be fit to plant out where they are to remain, as the younger the plants are, when planted out, the better they ſucceed; for though ſome ſorts will bear removing at a much greater age, young plants

plants put out at the ſame time will in a few years overtake the large ones, and ſoon outſtrip them in their growth; and there is an advantage in planting them by ſaving the expence of ſtaking and much watering which large plants require. It is often the caſe, with reſpect to plantations of pines, which were made of plants ſix or ſeven feet high, and at the ſame time others of one foot high planted between them, that in ten years the latter are better trees than the former, and much more vigorous in their growth; but if the ground, where they are deſigned to remain, cannot be prepared in proper time, the plants ſhould be removed out of the ſeed-beds into a nurſery, where they remain two years, but they ſhould not continue much longer on any account.

The beſt ſeaſon for planting out pine-trees, is the early ſpring, as March or the following month, juſt before they begin to ſhoot; for although the Scotch and ſome of the moſt hardy ſorts may be removed in the autumn or winter, eſpecially when they are growing in ſtrong land, where they can be taken up with balls of earth to their roots; it is not a practice to be generally adopted in other caſes.

In inſtances where theſe trees are planted in expoſed ſituations, they ſhould be put pretty cloſe together, eſpecially on the outſides, that they may ſhelter each other; and when they have grown a few years, part of the plants may be thinned out, to give room for the others to grow. But this muſt be gradually performed, leſt by too much opening the plantation at once, the air ſhould be let in among the remaining trees with too great violence, and ſtop their growth.

And wherever large plantations of theſe trees are deſigned to be made, the beſt method will be to raiſe the plants either upon a part of the ſame land, or as near to the place as poſſible, and alſo upon the ſame ſort of ſoil. A ſmall piece of ground will be ſufficient to raiſe plants enough for many acres. As the Scotch and larch kinds are capable of thriving upon the moſt barren ſands, where ſcarcely any thing elſe except heath and furze will grow, they may in many ſituations be extenſively planted; as there are many thouſand acres of ſuch land, which at preſent are of little benefit to any body, that might, by plantations of theſe trees, become of great value to their proprietors, and alſo a national benefit. It is in general the expence of making ſuch plantations, that chiefly operates againſt ſuch undertakings; though, when properly managed, it is much leſs than is commonly ſuppoſed, as the greateſt of the expence is that of fencing them from the cattle, &c. for the other is trifling, as there will be no neceſſity of preparing the ground to receive the plants; and the charge of planting an acre of land with theſe plants will not be more than thirty ſhillings, where labour is dear, excluſive of the plants, which may be valued at forty ſhillings more. Many acres of land have been planted with theſe trees, which were covered with heath and furze, merely by digging holes to put in the plants, and afterwards laying the heath or furze, which was put upon the ſurface of the ground, about their roots, to prevent the ground drying; few of which have failed; the plants being moſtly four years old from the ſeed. In five or ſix years, the pines have grown ſo well as to overpower the heath and furze, and deſtroy it, without their having had any further culture.

In regard to the diſtance at which they are generally planted in all large open ſituations, it is about four feet, but always irregular, avoiding planting in rows as much as poſſible; and in performing the work, great care is neceſſary not to take up the plants faſter than they can be planted out, ſome men being employed in digging up the plants, while others are planting. Thoſe who take up the plants ſhould be looked after, to ſee that they do not tear off their roots, or wound their bark; and as faſt as they are taken up, their roots ſhould be covered, to prevent their drying, and put into their proper ſituations as ſoon as poſſible. In planting them, it is adviſed that care ſhould be had to make the holes large enough for their roots, as alſo to looſen and break the clods of earth, and put the fineſt immediately about their roots, then to ſettle the earth gently with the foot to the roots of the plants. Where theſe circumſtances are duly attended to, and a proper ſeaſon choſen for performing it, there will be very little hazard of their ſucceeding; but where plantations are made with plants which are brought from a great diſtance, and which have been ſo cloſely packed up as to heat, and cauſe the leaves to become yellow, few of them will grow in a perfect manner.

In general, after the plantations are made, the only care they require, for four, five, or ſix years, is to ſecure the plants from cattle, hares, and rabbits; for if theſe are admitted to them, they make great deſtruction in a ſhort time: as where the branches are gnawed by hares or rabbits, it greatly retards the growth of the plants, if it does not wholly deſtroy them. In about this length of time after planting, the branches of the young trees meet, and begin to interfere with each other; therefore they require a proper thinning out. Some, however, adviſe pruning off the lower branches; but this muſt be done with great caution. The lower tier of branches only ſhould be cut off: this ſhould be performed in September, at which time there will be no danger of the wounds bleeding too much; and the turpentine will harden over the wounds as the ſeaſon grows cold, and prevent the wet from penetrating them. Theſe branches ſhould be cut off cloſe to the ſtems of the plants, and care be taken not to break any of the remaining branches of the young trees. This work ſhould be repeated every other year, at each time taking off only the lower tier of branches: for if the plants are much trimmed, it will greatly retard their growth, as it does in general that of all trees; but as theſe trees never put out any ſhoots where they are pruned, ſo they ſuffer more from amputation than thoſe which do. It is probably the beſt practice, in all caſes, to thin out the trees ſo as to let them have ſufficient room and air, as they can never be pruned in the branches without great injury. And in about twelve or fourteen years, they will require more thinning, where the plants have made good progreſs; but this ſhould be gradually performed, beginning in the middle of the plantation firſt, leaving the outſide cloſe, to ſcreen thoſe within from the cold, and by degrees coming to them, when thoſe which were firſt thinned will have had time to get ſtrength, and not be in danger of ſuffering from the admiſſion of cold air. When theſe plantations are thinned, the trees ſhould not be dug up, but their ſtems cut off cloſe to the ground, as their roots never ſhoot again, but decay in the earth; ſo there can be no harm in leaving them, and the roots of the remaining plants are not injured. The trees which are now cut will be fit for many purpoſes: thoſe which are ſtraight will make good putlocks for the bricklayers, and ſerve for ſcaffolding poles; ſo that there may be as much made by the ſale of theſe as will defray the whole expence of the planting, and probably alſo intereſt for the money firſt laid out for the whole.

And as the upright growth of theſe trees renders their wood the more valuable, they ſhould be left pretty cloſe together, in order to draw each other up, and grow tall. The naked ſtems of the trees ſometimes riſe more than ſeventy feet in height, and as ſtraight as poſſible; and as many boards have been ſawn from one of them, as laid the floor of a room near twenty feet ſquare. If theſe trees are left eight feet aſunder each way, it will be ſufficient room for their growth: therefore, if, at firſt thinning, a fourth part of the trees is taken away, the others may ſtand twelve or fourteen years longer, by which time they will be of a ſize for making ladders, and ſtandards for ſcaffolding, and many other purpoſes; ſo that from this ſale as much may be made, as not only to pay the remaining part of the expence of planting, if any ſhould be wanting in the firſt, but rent for the land with intereſt; and the ſtanding trees for fortunes for younger children, or other purpoſes.

But the great uſe and value of theſe ſorts of trees will be ſeen more fully under the proper heads. See PINE, *ſupra*.

PINE-*Tree*, in *Gardening*, the common fir-tree. See PINUS.

PINE-*Apple*, in *Metallurgy*, a word uſed to expreſs a ſort of mould, uſed in the refining of ſilver. It has this name from its ſhape, reſembling the fruit of that name.

When the refiners have taken the mixture of the ſilver and mercury together out of the cauldron, and ſtrained it through two coarſe wetted cloths, to make it the thicker, they then beat it with a ſort of battledores, to drive out yet more of the quickſilver; and ſtraining it again after this, they take out the remaining thick amalgam, and forming it into little pellets, they put theſe carefully into the moulds called pine-apples, preſſing them down. The amalgam, when put into theſe veſſels, or moulds, is uſually ſo rich as to be about one-fifth ſilver. The manner of diveſting this of the quickſilver afterwards is by means of fire; in which the quickſilver riſes in vapour, and the ſilver is left pure behind; but the careleſſneſs of the workmen in doing this, and particularly the uſing bad veſſels, or the not luting them cloſe, cauſes a waſte of this mineral greater than could be conceived. Alonſo tells us, that in the city of Potoſi alone, at the time of his writing, when the trading in metals ran but low, above thirty thouſand pieces of eight were waſted in quickſilver that was loſt one year with another. To prevent this, they then principally ſtudied the means of keeping the ſilver as dry of quickſilver as they could, in the pine-apple; but it then holding four-fifths of the whole maſs in quickſilver, the great waſte was in the ſeparating it afterwards. See POTOSI.

PINE-*Martin*, in *Zoology*. See MUSTELA *Martes*.

PINE-*Salt*, a name given to a preparation of the bark of the pine-tree, uſed as a ſort of ſeaſoning to food in the manner in which we uſe ſalt.

The Laplanders are very fond of this; and the manner of their preparing it is given in Scheffer's hiſtory of that country. They peel off the bark from the lower part of the bodies of thoſe trees, and ſeparating the outer rough part, they take the inner bark, which they carefully divide into its ſeveral thin coats: when they have thus reduced them to as thin pieces as they can, they expoſe them to the ſun in their ſummer months to dry; and when thoroughly dried, they tear them into thin and narrow ſlips, and put them up in boxes made of the outer bark of other trees freſh taken off. They bury theſe boxes in deep holes dug in the ſands, and let them remain thus one day; on the day following, they bring together a number of ſtumps of trees, and other wood, and laying them over the place where the bark is buried, they ſet them on fire; the next day they take out their buried boxes, and the heat having penetrated ſo deep into the earth in a mild degree, the bark is found to have been greatly affected by it, and to have received a red colour, and a very agreeable flavour, ſomewhat ſweetiſh. This is their general ſauce: they eat it with all their food, as we do ſalt; but it has ſo little of the nature of ſalt, that the name is ill adapted to it.

There is another vegetable ſubſtance, which, though of a diſagreeable taſte to us, yet cuſtom teaches them to be fond of. This is the angelica petroſa: they cut the large ſtalks of this plant before it runs to ſeed, and roaſt them; they eat this in conſiderable quantities with their pine-ſalt, and eſteem it not only an agreeable, but a more than ordinary wholeſome ſort of food.

PINE, in *Geography*, a townſhip of America, in Allegany county, Pennſylvania, containing 588 inhabitants.

PINE-*Creek*, a townſhip of America, in Lycoming county, containing 397 inhabitants.

PINE-*Creek*, a river of America, in Pennſylvania, which runs into the weſt branch of the Suſquehannah, N. lat. 41° 11′. W. long. 77° 22′.

PINE *River*, a river of America, which runs into lake Huron, N. lat. 45° 42′. W. long. 84° 25′.—Alſo, a river of America, which runs into the Wabaſh, N. lat. 40° 15′. W. long. 87° 18′.—Alſo, a river of Canada, which runs into lake Huron, N. lat. 44° 44′. W. long. 80° 26′.

PINE *Iſland*, a ſmall iſland in the gulf of Mexico, near the ſouth coaſt of Weſt Florida. N. lat. 30° 18′. W. long. 88° 18′.

PINEA, in *Botany*. See PINUS.

PINEA, or *Pigne*, in *Commerce*, a term uſed in Peru and Chili, for a kind of light, porous maſſes or lumps, formed of a mixture of mercury and ſilver-duſt from the mines.

The ore, or mineral, of ſilver, being dug out of the veins of the mine, is firſt broken, then ground in mills for the purpoſe, driven by water with iron peſtles, each of two hundred pounds weight. The mineral, thus pulveriſed, is next ſifted; then worked up, with water, into a paſte; which, when half dry, is cut into pieces, called *cuerpos*, a foot long, weighing each about two thouſand five hundred pounds.

Each cuerpo is again kneaded up with ſea-ſalt, which, diſſolving, incorporates with it. They then add mercury, from ten to twenty pounds for each cuerpo, kneading the paſte afreſh until the mercury be incorporated with it. This office being exceedingly dangerous, on account of the noxious qualities of the mercury, is always made the lot of the poor Indians.

This amalgamation is continued for eight or nine days; and ſome add lime, lead, or tin ore, &c. to forward it; and, in ſome mines, they are obliged to uſe fire. To try whether or no the mixture and amalgamation be ſufficient, they waſh a piece in water; and if the mercury be white, it is a proof that it has had its effect; if black, it muſt be further worked.

When enough, it is ſent to the lavatories, which are large baſons that empty ſucceſſively into one other. The paſte, &c. being laid in the uppermoſt of theſe, the earth is then waſhed from it into the reſt by a rivulet turned upon it; an Indian, all the while, ſtirring it with his feet, and two other Indians doing the like in the other baſons.

When the water runs quite clear out of the baſons, they find the mercury and ſilver, at bottom, incorporated. This matter they call *pella*, and of this they form the *pineas*, by expreſſing as much of the mercury as they can; firſt, by putting it into woollen bags, and preſſing and beating it ſtrongly; then, by ſtamping it in a kind of wooden mould, of an octagonal form, at the bottom of which is a brass plate pierced full of little holes.

The matter, being taken out of the mould, is laid on a trivet, under which is a large vessel full of water; and the whole being covered with an earthen head, a fire is made around it.

The mercury still remaining in the mass is thus reduced into fumes, and at length condensing, it is precipitated into the water, leaving behind it a mass of silver grains of different figures, which only joining or touching at the extremes, render the matter very porous and light.

This, then, is the pinea, or pigne, which the workmen endeavour to sell secretly to vessels trading to the South sea; and from which those who have ventured to engage in so dangerous a commerce, have made such vast gains. Indeed, the traders herein must be very careful; for the Spanish miners are errant knaves, and to make the pignes weigh the more, they make a practice of filling the middle with sand, or iron.

PINEAL Gland, in *Anatomy*, a small conical body, about the size of a pea, in the brain. See Brain.

PINEAU, Gabriel du, in *Biography*, a celebrated French lawyer, was the son of an eminent advocate at Angers, where he was born in 1573. He practised first at his native place, then at Paris, and afterwards was created by Mary de Medicis her master of requests. In her differences with the court, she sought to support herself by his counsels; but, faithful to his sovereign, he continually advised her to an accommodation, which was at length effected. By Lewis XIII. he was nominated mayor and captain-general of Angers in 1632. The integrity and impartiality with which he performed the duties of his station, caused him to be called the father of the people. His house was, at length, made a kind of academy, in which conferences were held on points of law for the instruction of members of the profession, and others. He was exact in the performance of his religious duties, and exemplary in his conduct. He died at the age of 71, in the year 1644. His writings are, "Latin Notes on the Canon Law, in opposition to those of Du Moulin;" "A Latin Commentary on the Custom of Anjou;" "Consultations on several important Questions relative to the Custom of Anjou and to the French Law, with Dissertations on various Subjects:" these were reprinted in 2 vols. folio, 1725. Moreri.

PINEDA, Juan de, a native of Medina del Campo, and author of an universal history under the title of "Le Monarquia Ecclesiastica." He was an indefatigable writer; his commentaries alone filled 6826 leaves in folio. The most useful of his labours, however, was that of editing and abridging a very curious book, entitled "El Paso Honroso defendido por Suero de Quinones," of which a new edition was printed at Madrid in 1783. Pineda was a Franciscan, and lived to the age of fourscore. There is another writer of the same name, who lived about the same time, a Jesuit, who was of such estimation, that once when he passed through Evero, he was received in the Jesuit college there, and a monument was afterwards erected with this inscription, "Hic Pineda fuit." The task of compiling the great "Index Expurgatorius," published in 1640, was performed by him. He also published a funeral oration for that extraordinary woman Donna Luisa de Carvajal y Mendoza, in the English seminary at Seville.

Pineda, in *Geography*, a town of Spain, on the coast of Catalonia; 12 miles N.E. of Mataro. N. lat. 41° 37′ E. long. 2° 35′.

PINEG, a town of Russia, in the government of Archangel, on the Pinega; 48 miles E. of Archangel. N. lat. 64° 30′. E. long. 41° 26′.

PINEGA, a river of Russia, which rises in the province of Usting, and runs into the Dwina; eight miles E. from Cholomgori, in the government of Archangel.

PINEGROVE, a township of America, in Berks county, Pennsylvania, containing 1290 inhabitants.

PINEI *nuclei Maluccani sive pergatorii*, *J. B. Pinus Indica nucleo purgante C. B. Pinei nuclei Maluccani*. Park., in *Botany*, a species of the croton in the Linnæan system. There grows, says Acosta, in some gardens of Malabar, and also wild, in some woods, a tree of the bigness of a pear-tree, whose leaves are of a watery-green beneath, and of a dead green on the upper face, and are very tender and soft. They are of a very acrid taste, and vellicate the tongue for a long while afterwards: the fruit is triangular, of the size of a filberd, and divided into many capsules, containing each a round sort of white or dark greenish seed, equal to a pine-kernel, when taken out of its shell.

The Indians, as Acosta says, take a couple of the kernels, peel them, and then pound them, and mix them in clysters, against difficulty of urine, and the pain of the sciatica; or exhibit them in cock-broth, for the evacuation of putrid, slimy, gross, and cold humours, and particularly for the cure of an asthma. They anoint the impetigo with these kernels, bruised in water, and so cure it; but they are very burning. The cathartic pine-kernels, as Monardes says, purge very strongly bile, phlegm, and water; and though milder than filberds, excite vomiting. When roasted, they operate with less violence, and fewer gripes. They are exhibited in chronic diseases, and have a peculiar virtue of evacuating gross humours.

The fruit of this tree is the grana tiglia of other writers. It is intensely hot and acrimonious; and so violent an evacuant, that it cannot be taken with any tolerable safety. This, as well as the pinhones Indici, and avellana purgatrix, which is a species of the jatropha, in the Linnæan system, yield upon expression a considerable quantity of oil, impregnated more or less with the taste and purgative quality of the seeds; but they all appear too drastic to be ventured on in substance. The wood and leaves of the plants are likewise strong cathartics.

PINELLI, Gianvincenzo, in *Biography*, an eminent patron of literature, was born of Genoese parents, at Naples, in 1535. From a very early period he entered with so much earnestness into literary pursuits, that besides the ancient and several modern languages, there was scarcely any branch of science which he had not acquired. At the age of twenty-three he left Naples for Padua, where he had improved himself by his acquaintance with many eminent scholars. In 1561 he was recommended to Philip II. as the fittest person to undertake a history of Charles V. He is applauded by other learned persons of high estimation on account of his literary and moral qualifications. Though from his rank and situation he might have aspired to the most important stations, yet his fondness for letters, joined to a delicate habit of body, led him to pass his days in retirement. His house was a kind of academy, frequented by the literati, who found in him a munificent patron, and an enlightened director of their studies. He collected a numerous library of books; expensive mathematical and astronomical instruments; a cabinet of fossils and minerals; together with maps, plates, and every thing that could facilitate learned research. He died in 1601, and the fate of his fine library was very remarkable. After his death, the senate of Venice set its seal upon his manuscripts, and took away all that related

to

to the affairs of the republic, amounting to 200. There were besides 14 chests of MSS., which, with 116 chests of printed books, were embarked in three ships to be conveyed to Naples, where his heirs resided. One of them fell into the hands of the corsairs, who, considering the books as mere lumber, threw them overboard; the rest were scattered on the beach at Fermo, which was entirely covered with papers. These were totally disregarded, till the bishop of the place having collected all he could, sent them to Naples. In this state the library was purchased by cardinal Borromeo at the price of 3400 gold crowns.

PINES, *Island of*, in *Geography*, a small island on the N.W. of Terra Firma, about 41 leagues E. of Porto Bello, which forms a good harbour, with two other small islands and the main land. N. lat. 9° 12'. W. long. 80° 15'. The river of Pines is five miles from the above harbour.

PINES, *Pinez*, or *Pinas*, an island in the Caribbean sea, near the S.W. coast of Cuba, about 25 miles long, and 15 broad. N. lat. 21° 30'. W. long. 83° 25'.

PINES, *Bay of*, a bay on the coast of West Florida. N. lat. 30° 20'. W. long. 88° 21'.

PINES, *Island of*, an island in the South Pacific ocean, near the coast of New Caledonia; about 15 or 16 miles in length, in a S.E. and N.W. direction, high in the central part, and sloping towards the extremities. S. lat. 22° 38'. E. long. 167° 38'.

PINET, ANTHONY DU, in *Biography*, lord of Norroy, who flourished in the 16th century, was a native of Besançon in the Franche Comtè, concerning whom we know nothing but that he was zealously attached to the Protestant religion, in behalf of which he wrote several books. He was likewise author of "Plans, Draughts, and Descriptions of several Towns and Fortresses, as well in Europe, Asia, and Africa, as in the Indies and America, their foundations, antiquities, and manners of living, &c." He translated Pliny's Natural History in 2 vols. folio, and many other works of repute. Bayle. Moreri.

PINETUS, in *Ancient Geography*, a town of Spain, on the route from Bracara to Asturica, between Ad Aquas and Roboretum, according to Antonine's Itinerary, attributed by Ptolemy to the Callaici.

PINETZKOI, in *Geography*, a town of Russia, in the government of Archangel, on the Dwina; 60 miles S.S.E. of Archangel.

PINEVILLE, a town of America, in South Carolina, in St. Stephen's district, which has a flourishing academy, between 20 and 30 dwelling houses, 150 white inhabitants, and 300 negroes. In its vicinity is a valuable quarry of brown iron-stone, the only one found in the low country of Carolina.

PINEY, a town of France, in the department of the Aube, and chief place of a canton, in the district of Troyes; 12 miles N.E. of Troyes. The place contains 1456, and the canton 5920 inhabitants, on a territory of 250 kiliometres, in 13 communes.

PING-CHAN, a city of Corea; 35 miles S. of Hoang-tcheou.

PING-CHAN-PO, a small island, with a town, near the S. coast of Corea. N. lat. 34° 8'. E. long. 126° 22'.

PING-HAI, a town of Corea; 115 miles S.E. of King-ki-tao. N. lat. 36° 47'. E. long. 128° 41'.

PING-ING, a town of Corea; 40 miles S. of Koang-tcheou.

PING-KING, a city of China, of the first rank, in Koei-tcheou. N. lat. 26° 38'. E. long. 106° 56'.

PING-LIANG, a city of China, of the first rank, in Chen-si. N. lat. 35° 35'. E. long. 106° 18'.

PING-LO, a city of China, of the first rank, in Quang-si. N. lat. 24° 22'. E. long. 110° 4'.

PINGNAVIR, a town of Africa, in Querimba. S. lat. 11° 55'. E. long. 41° 10'.

PINGRE', ALEXANDER-GUY, in *Biography*, a French mathematician and astronomer, was born at Paris in 1711. In 1727 he became a member of the canons regular of the congregation of France. He was intended for the church, but after a few years' study of theology he devoted himself entirely to the sciences. In 1749 he was appointed a member of the Academy of Sciences in Rouen, and was elected to fill the office of astronomer, and attained to first rate excellence. His earliest production, as an author, was the "Calculation of an Eclipse of the Moon," on the 23d of December 1749. In May 1753 he was elected correspondent of the Academy of Sciences at Paris, after having sent them an observation of the transit of Mercury, which he made at Rouen. He was next appointed librarian of the abbey of St. Genevieve, obtained the construction of an observatory, and was furnished by the abbot and chapter with a six-foot telescope, while he had the loan of an excellent quadrant from the academy. At the desire of Monnier, he next engaged in calculating "A Nautical Almanack," to enable navigators more easily to ascertain the longitude by means of lunar observations. He calculated a table of the eclipses visible of the sun and moon from the commencement of the Christian era to the year 1900, and afterwards a table of the eclipses visible from the northern pole to the equator, for a thousand years before our era. The utility of these labours for verifying historical dates, induced the Academy of Inscriptions to insert a part of them in the 42d volume of their Memoirs. He published the "State of the Heavens" for the year 1754; in this the moon's place was calculated with the utmost exactness according to the tables of Dr. Halley for noon and midnight, with the right ascension in seconds of time twice a day. In 1758 he published "A Memoir relating to the Discoveries made in the South Sea, during the Voyages of the English and French rouud the World." In 1760, Pingrè left France for the island of Rodriguez in the Indian ocean, to observe the transit of Venus that was to take place in the following year, and on the 6th of June of that year he made his observations, from which he concluded that the parallax of the sun was 10".2. At the same time the English astronomer Mason concluded from the observations which he made at the Cape of Good Hope, that the parallax was 8".2. La Lande, in his "Astronomy," published in 1764, adopted a medium between these conclusions, and supposed the parallax to be 9", in which he was followed by astronomers in general, till more numerous observations made on the transit of 1769 led to a different result. After the return of Pingrè from the East, he published a description of Pekin, in which he shewed the position of that capital from the result of a number of calculations of eclipses, and ascertained its longitude, by other calculations, with a degree of precision to which none of the labours of the scientific missionaries had any pretensions. In 1769 he sailed for the island of St. Domingo, on board the Isis man of war, to observe the transit of Venus, and performed the service committed to him in the most able and satisfactory manner possible. An account of this voyage, which proved of considerable importance to the science of geography, as well as astronomy, appeared in 1773, in two vols. 4to. After comparing the results of the immense number of calculations made by the observers of the transit in the year 1769, the sun's parallax has been concluded to be about 8".6. (See VENUS, *Transit of*.) In 1771, Pingrè made

made another voyage, on board the Flora frigate, with the view of extending the interefts of geographical and aftronomical knowledge, having with him, as the companion of his purfuits, the chevalier de Borda, a celebrated engineer and geometrician; the account of their proceedings, obfervations, and experiments, was publifhed in 1778, in two vols. 4to. In 1784, M. Pingrè publifhed his Cometography, or hiftorical and theoretical treatife on Comets, in two vols. 4to., which is his moft confiderable work, and contains calculations of the orbits of all the comets of which an account has been preferved. After a long life fpent in the moft important fervices to the world, he died in the month of May 1796, leaving behind him a high character for integrity, having enjoyed the efteem of the public as well as that of his friends. He was author of many other works befides thofe that have been already noticed.

PING-TCHAI, in *Geography*, a town of Corea; 40 miles W. of Ou-tchuen.

PING-TCHANG, a town of Corea; 63 miles E. of King-ki-tao.

PINGUAGUEM, a river of Africa, which runs into the Zambeze, S. lat. 18° 10'.

PINGUEDO, in *Anatomy*, the Latin term for fat.

Some reftrain pinguedo only to that humid foft kind of fat found in animals, next under the fkin. See ADEPS.

PINGUICULA, in *Botany*, the diminutive of *pinguis*, fat, which alludes to a peculiar appearance of greafinefs upon the leaves; whence arofe the Englifh name of Butterwort, and the French one of Graffette, for the plant in queftion.—Linn. Gen. 13. Schreb. 19. Willd. Sp. Pl. v. 1. 109. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 26. Ait. Hort. Kew. v. 1. 44. Juff. 98. Lamarck Illuftr. t. 14. Gærtn. t. 112.—Clafs and order, *Diandria Monogynia.* Nat. Ord. *Corydales*, Linn. according to his own opinion, but we fhould rather have referred it to his *Perfonatæ;* akin to *Lyfimachiæ*, Juff. rather to his *Pediculares;* the flower agrees beft with the latter, the fruit with the former. Its proper place however is in the new order of *Lentibulariæ*, founded by Richard, and adopted in Brown's Prodr. Nov. Holl. v. 1. 429.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, fmall, permanent, ringent; upper lip erect, three-cleft; lower reflexed, divided. *Cor.* of one petal, ringent; its border more or lefs equally five-cleft. Nectary a fpur, elongated from the bafe of the petal behind. *Stam.* Filaments two, cylindrical, curved upwards, fhorter than the calyx; anthers roundifh, clapped clofe to the ftigma. *Pift.* Germen fuperior, globofe; ftyle very fhort; ftigma two-lipped, the upper lip larger, flat, reflexed, covering the anthers, the lower very narrow, erect, cloven, fhorteft. *Peric.* Capfule roundifh or ovate, burfting at the top by two valves, with one cell. *Seeds* numerous, cylindrical. *Recept.* central, unconnected.

Eff. Ch. Corolla ringent, fpurred. Calyx two-lipped, in five fegments. Stigma two-lipped. Capfule fuperior, of one cell, with many feeds.

1. P. *lufitanica.* Pale Butterwort. Linn. Sp. Pl. 25. Engl. Bot. t. 145. (P. villofa; Lightf. Scot. 77. t. 6. Viola paluftris, Pinguicula dicta, lufitanica; Grifl. Virid. 84.)—Nectary obtufe, fhorter than the nearly regular petal. Flower-ftalk hairy. Capfule globofe.—Native of Portugal according to Grifley, whofe plant we have verified. It is found alfo on the borders of bogs in Dorfetfhire, Hampfhire, Devonfhire, and Cornwall, as well as in the weft of Scotland and Ireland. It is perennial, flowering in June and July. Like all the reft of its genus this herb is deftitute of a *ftem*, the *leaves* being radical, fpreading, ovate, obtufe, vifcid, pale with red reticulated veins; their edges involute. *Stalks* feveral, erect, fimple, flightly hairy, three or four inches high, each bearing an elegant little *flower*, whofe limb is of a pale lilac, in five nearly equal, emarginate fegments, the tube yellow, ftreaked with red, hairy at the mouth. *Stigma* very unequally two-lipped, concave. *Capfule* exactly globular. The fhape of the part laft mentioned affords excellent fpecific characters in this genus, but is not uniform enough in all to enter into the generic defcription.

2. P. *cryftallina.* Cryftalline Butterwort. Sm. Fl. Græc. Sibth. v. 1. 8. t. 11.—Nectary obtufe, fhorter than the very irregular fix-cleft petal. Segments of the calyx oblong. Flower-ftalk fmooth at the bafe.—Gathered by Dr. Sibthorp and Mr. Ferdinand Bauer, in watery places near Camandria, in the ifle of Cyprus. Differs from the former in its uniformly glaucous *leaves*, unmarked by red veins, but diftinguifhed by a glandular cryftalline clothing like the ice-plant. The *flowers* are fimilar in colour to *P. lufitanica*, but very different in ftructure; the fegments of their *calyx* being almoft linear, not broadly ovate; and the limb of their *corolla* diftinctly two-lipped, its upper lip fhort, in two divaricated lobes, the lower much broader and longer, in three lobes, the middle lobe deeply cloven. The *germen*, and probably the *capfule*, is globofe.

3. P. *vulgaris.* Common Butterwort. Linn. Sp. Pl. 25. Fl. Dan. t. 93. Engl. Bot. t. 70. (P. five Sanicula Eboracenfis; Ger. Em. 788.)—Nectary cylindrical, acute, as long as the very irregular five-cleft petal. Segments of the calyx oblong. Capfule ovate. Common on the bogs of Europe, flowering with us in May and June. Larger than either of the foregoing. The tube and fpur of the *corolla* are pale purple, but the limb is deep blue, in five rounded fegments, of which the two uppermoft are much the fmalleft, the lower central one the largeft, all of them entire. The vifcid fubftance, found on the leaves, is faid to be ufeful to anoint the dugs of cows when fore or injured; at leaft fuch is the report of old Gerarde, and hence came the name of Yorkfhire Sanicle for this plant.

4. P. *grandiflora.* Large-flowered Butterwort. Willd. n. 3. Decand. Fl. Franc. v. 1. 250. v. 3. 575. Lamarck Dict. v. 3. 22. Illuftr. t. 14. f. 2. Engl. Bot. t. 2184.—Nectary cylindrical, acute, as long as the nearly regular, five-cleft, veiny petal. Segments of the calyx ovate, obtufe. Capfule ovate.—Native of France and Ireland. It was difcovered by Mr. Drummond, curator of the botanic garden at Cork, in marfhy ground in the weft part of that county, very abundantly, flowering in May. The *leaves* are nearly twice as large as *P. vulgaris*, which is not found in that neighbourhood. *Flowers* alfo twice the fize of that fpecies, on ftronger more vifcid *ftalks*. *Corolla* much more equally divided, and particularly diftinguifhed by its fine reticulations of dark-blue veins.

5. P. *alpina.* Alpine Butterwort. Linn. Sp. Pl. 25. Fl. Lapp. ed. 2. 11. t. 12. f. 3. Fl. Dan. t. 453. Gunn. Norv. fafc. 2. 71. t. 4. f. 4.—Nectary conical, deflexed, fhorter than the tube of the very irregular five-cleft petal. Capfule oblong, beaked.—Native of the alps of Lapland, Switzerland, and Auftria, flowering in June, earlier in that country than the *vulgaris*, according to Gunner. It is like that fpecies in foliage, but rather fmaller, and effentially different in *fpur* and *capfule*. The *corolla* is white, with a yellow palate; its fegments very unequal, rounded, undivided.

6. P. *villofa.* Little Hairy Butterwort. Linn. Sp. Pl. 25. Fl. Lapp. ed. 2. 12. t. 12. f. 2. Lapland Tour, v. 1.

v. 1. 255. v. 2. 109.—Nectary awl-ſhaped, ſhorter than the petal. Capſule inverſely heart-ſhaped, compreſſed. Flower-ſtalk hairy.—Gathered by Linnæus amongſt bog-moſs in Lapland, but rarely. It has alſo been found occaſionally in Norway and Siberia. This is much ſmaller than any of the foregoing, flowering in May or June; the foliage being withered, and ſeed ripe, by July. The *leaves* are rounded and three-ribbed. *Stalk* ſlender, ſtraight, finely hairy or downy. *Corolla* pale violet. *Capſule* emarginate. Linnæus originally confounded Ray's ſynonyms of the *luſitanica* with the preſent ſpecies, which by that means came to be reckoned a Britiſh plant.

PINGUIN, a Weſt Indian name, adopted as generic by Dillenius, in Hort. Elth. 320. t. 240. See BROMELIA, n. 4.

PINGUIN, in *Ornithology*, is made a diſtinct genus of birds, of the order of web-footed, by Mr. Pennant; the characters of which are, that the bill is ſtrong, ſtraight, and bending a little towards the point; the tongue is covered with ſtrong ſharp ſpines, pointing backwards; the wings are very ſmall, pendulous, uſeleſs for flight, and covered with mere flat ſhafts; the body is covered with thick ſhort feathers, with broad ſhafts, placed as compactly as ſcales; the legs are ſhort and thick, placed quite behind; the toes are four, ſtanding forward, the interior looſe, the reſt webbed; and the tail is very ſtiff, conſiſting only of broad ſhafts. He has enumerated and deſcribed three ſpecies; *viz.* 1. The Patagonian pinguin, which inhabits an iſle near the Cape of Good Hope, on the coaſts of New Guinea, the iſle of Deſolation, ſouth of the Cape, the ſouthern parts of America, and the ſeas among the ice, as high as ſouth lat. 64° 12′, long. 38° 14′ eaſt. It lives much at ſea; the wings act as fins; it burrows on land, and is analogous to ſeals. The name pinguin is given to theſe birds, he ſays, *propter pinguedinem*, on account of their fatneſs; and he obſerves, that it has been corrupted to *penguin;* ſo that ſome, imagining it to be a Welch word, ſignifying *white head*, entertained ſome hopes of tracing the Britiſh colony, ſaid to have migrated into America, under Madoc Gwineth, ſon of Owen Gwineth, A.D. 1170. But he adds, as the two ſpecies of birds that frequent that coaſt have black heads, we muſt reſign every hope, founded on that hypotheſis, of retrieving the Cambrian race in the new world. 2. The leſſer pinguin, diomedea demerſa of Linnæus, or anſer Magellanicus of Cluſius. And, 3. The red-footed pinguin, the phæton demerſus of Linnæus, inferior to the laſt in ſize, with a thick, arched red bill; plumage like the former in texture; the head, hind part of the neck, and the back, of a duſky purpliſh hue, and breaſt and belly white; brown wings, with the tips of the larger feathers white: inſtead of a tail, a few black briſtles; and red legs. It is found on Pinguin iſle, near the Cape of Good Hope. Phil. Tranſ. vol. lviii. art. 14. See ALCA and APTENODYTA.

PINHEIRA *de Azere*, in *Geography*, a town of Portugal, in the province of Beira, on the Mondego; 15 miles S.W. of Viſeu.

PINHEL, a town of Portugal, in the province of Beira, ſituated on a mountain, and fortified; containing ſix pariſh churches, and about 1600 inhabitants; ſeven miles N.E. of Almeida. N. lat. 40° 33′. W. long. 6° 44′.

PINHONES INDICI, the name by which the Portugueſe call the purging nuts, as they are called, of America; the fruit of the jatropha foliis cordatis angulatis in the Linnæan ſyſtem, or the ricinoides and curcas of other writers. It is called Barbadoes nut; and has an oval, walnut-like fruit, with oblong black ſeeds. Their taſte is ſweetiſh, nauſeous, and acrid; and they are powerful evacuants. In America it is ſaid to be taken in conſiderable quantities, and to purge without much inconvenience. See PINEI *nuclei*, &c.

PINION, in *Mechanics*, an arbor, or ſpindle, in the body whereof are ſeveral notches, into which catch the teeth of a wheel that ſerves to turn it round.

Or a pinion is a leſſer wheel, which plays in the teeth of a larger. See WHEEL.

In a watch, &c. the notches of a pinion (which are commonly 4, 5, 6, 8, &c.) are called *leaves*, and not teeth, as in other wheels.

PINION *of Report* is that pinion, in a watch, which is commonly fixed on the arbor of a great wheel, and which in old watches uſed to have but four leaves; it drives the dial-wheel, and carries about the hand.

The quotient, or number of turns, to be laid upon the pinion of report, is found by this proportion: as the beats in one turn of the great wheel are to the beats in an hour; ſo are the hours of the face of the clock (*viz.* 12, or 24) to the quotient of the hour-wheel or dial-wheel divided by the pinion of report, that is, by the number of turns which the pinion of report hath in one turn of the dial-wheel; which, in numbers, is 26928 : 20196 :: 12 : 9.

Or rather thus: as the hours of the watch's going are to the numbers of the turns of the fuſee; ſo are the hours of the face, to the quotient of the pinion of report. If the hours be 12, then 16 : 12 :: 12 : 9. But if 24, the proportion is 16 : 12 :: 24 : 18.

This rule may ſerve to lay the pinion of report or any other wheel, thus: as the beats, in one turn of any wheel, are to the beats in an hour; ſo are the hours of the face, or dial-plate, of the watch, to the quotient of the dial-wheel, divided by the pinion of report, fixed on the ſpindle of the aforeſaid wheel. See CLOCK and MOVEMENT.

PINION, *Flying*. See FLYING.

To PINION is to bind the hands or arms of a perſon, ſo as to prevent his having the free uſe of them.

PINIROLO, in *Ornithology*, the name of a bird of the tringa kind, ſomewhat approaching to the ſand-piper, but larger; its beak is little more than a finger's breadth long, and black; it is of a mixed cheſnut colour, and brown on the back; and its belly and breaſt are perfectly white: it is common in the Italian markets, and very much reſembles the common tringa.

PINITE, in *Mineralogy*, a ſpecies of the clay genus, is of a blackiſh-grey colour, which is frequently covered, on the ſurface and in rents, with iron ochre. It occurs ſeldom maſſive; is almoſt always cryſtallized, and that in ſix-ſided priſms, with truncated lateral edges and angles; ſometimes the truncating edges are ſo numerous, that the cryſtal acquires a roundiſh aſpect. The cryſtals are frequently middle-ſized, ſometimes ſmall, and they frequently interſect each other. The external luſtre is not at all certain; internally it is gliſtening, and its luſtre is reſinous. Its longitudinal fracture is ſmall-grained and uneven; the croſs-fracture is imperfect and foliated. The fragments are indeterminately angular, ſometimes blunt-edged. On the edges it is ſlightly tranſlucent; it is ſoft, eaſily frangible, and not particularly heavy; the ſpecific gravity, according to Kirwan, is 2.98. With regard to its chemical character, it experiences no alteration before the blow-pipe, either alone or with the addition of borax. With carbonate of ſoda it forms an opaque ſcoriaceous globule; and with microcoſmic ſalt, it makes a tranſparent opaleſcent glaſs. It conſiſts of

Alumine

Alumine	63.75
Silica	29.50
Oxyd of Iron	6.75
	100.00

It has been hitherto found only in the mine called Pini, at Schneeberg in Saxony, and from the mine it derives its name; it is usually accompanied with quartz, feldspar, and mica.

PINK, in *Botany*, *Gardening*, &c. See DIANTHUS.

PINK, *Indian*, a species of *ipomoea*; which see.

PINK, *Indian*, is also a species of *lonicera*; which see.

PINK, *Montpelier*. See APHYLLANTHES.

PINK, *Sea*. See THRIFT.

PINK, *Brown*, among *Painters*, is the tinging part of some vegetable of a yellow or orange-colour, precipitated upon the earth of alum, cuttle-fish bone, or some similar calcareous substance. When good, it is a concentrated yellow, which, as a pigment, is transparent in oil, gives the effect of a dark colour, and serves for deep shades. There are many methods of preparing brown pink. One of the best and most common methods is the following: take of the French berries, one pound; of fustic wood in chips, half a pound; and of pearl-ashes, one pound. Boil them in a tin boiler, with a gallon and a half of water, for an hour; and then strain off the tincture through flannel, while the fluid is boiling hot. Having prepared in the mean time a solution of a pound and a half of alum, put it gradually to the tincture, as long as an ebullition shall appear; wash the sediment, as in the preparation of *lakes* (which see); and when it is brought, by filtering through paper with a linen cloth, to a proper consistence, dry it on boards in square pieces. Or, it may be made without the use of salts, by boiling two pounds of the berries in a gallon of water for two hours, and straining off the tincture through flannel. In the mean time prepare a pound and a half of cuttle-fish bone, by levigating the soft inner part with water on a marble; add this to the tincture, and evaporate them in balneo Mariæ till the matter becomes of a stiff consistence: when the whole has been well mixed by grinding, let it be laid on boards to dry.

The goodness of brown pink must be judged of by its transparency, and force of colour, when mixed with oil; but its qualities of standing well, and not fattening in oil, in both which respects it is commonly defective, can only be ascertained by trial and experience.

PINK, *Dutch*, is a pigment formed of chalk, coloured with the tinging particles of French berries, or other vegetables. It is principally used for coarser purposes in water. It may be made by boiling one pound of French berries, and four ounces of powdered turmeric root in a gallon of water for two hours, and then straining off the tincture through flannel, and boiling it again with an ounce of alum, till it be evaporated to one quart. Prepare in the mean time four pounds of chalk, by washing it over, and afterwards drying it; and mix the chalk with the tincture, by grinding them together, and then dry it on boards. It is sometimes prepared in the same manner with starch and white lead. Its goodness consists in its being of a full gold-coloured yellow, and very bright.

PINK, *English*, is only a lighter and coarser kind of Dutch pink; and may be prepared in the same manner, the quantity of chalk being increased in proportion, as it is intended to be inferior to the Dutch.

PINK, *Light*, is of two kinds; the one being the same with the Dutch pink, only with much less colour, so that the proportion of the French berries and turmeric must be lessened to one-half: the other is the same with the brown pink, that is, transparent in oil, but with less colour. It may be prepared by boiling one pound of French berries in a gallon of water, for an hour, and adding to the strained fluid two pounds of pearl-ashes, dissolved and purified, by filtering through paper; then precipitate with alum dissolved in water, by adding the solution gradually, till the ebullition ceases; and proceed as with brown pink.

PINK, *Rose*, is a lake, the earth or basis of which is principally chalk, and the tinging substance is extracted from Brasil or Campeachy wood. This pigment, which does not stand, is seldom employed, except for the coarse work of house-painters, or for paper-hangings, and sometimes with varnish. It may be prepared by boiling six pounds of Brasil wood, or three pounds of Brasil and three of Campeachy wood, in three gallons of water, in which a quarter of a pound of alum has been dissolved, for an hour. Purify the fluid, by straining through flannel, and put back the wood into the boiler with the same quantity of alum, and proceed as before; repeating the operation a third time; mix the three quantities of tincture together, and evaporate them till only two quarts of fluid remain. Prepare eight pounds of chalk, by washing it over in water, in which a pound of alum has been dissolved, and afterwards fusing the chalk from the salt, formed by the alum, and drying it to the consistence of a stiff clay. Grind the chalk and tincture together; and lay the mass to dry out of the sun or cold air. The goodness of rose pink consists chiefly in the brightness of the colour, and fineness of its substance.

PINK, *Pinque*, *Fr.* in *Sea Language*, is a name given to a ship with a very narrow stern; whence all vessels, however small, whose sterns are fashioned after this manner, are called *pink-sterned*.

Pinks are Mediterranean vessels, which differ from the xebec only in being more lofty, and not sharp in the bottom, as they are vessels of burthen. They have long narrow sterns, and three masts, carrying latteen-sails.

PINKUFELT, in *Geography*, a town of Hungary; 10 miles W. of Steinam Anger.

PINKZOW, a town of Poland, in the palatinate of Sandomirz; 52 miles W. of Sandomirz.

PINNA, or PENNA, a Latin word signifying a feather. It is also used figuratively, in divers arts, to express things which bear some resemblance, in form, to feathers; as the fins of fishes, &c. See FIN.

PINNA, *the Nacre*, in *Conchology*, a genus of the class and order Vermes Testacea. The generic character is; animal a limax; shell bivalve, fragile, upright, gaping at one end, and furnished with a byssus or beard; the hinge is without teeth, the valves are united in one. The inhabitants of these shells produce a large quantity of fine and very strong byssus, which by the Italians is woven into a sort of silk. The shells of all the species, of which there are eighteen, are generally found standing erect in the smoother waters of the bays, with the larger end a little open. The fish of many of them are highly esteemed as food.

Species.

RUDIS. Shell vaulted, with arched scales arranged in rows. There is a variety: the *first* inhabits the American and Atlantic oceans, is from twelve to sixteen inches long, and from four and a half to eight broad; the shell is red, and it has from six to eight grooves. The *second* is found in the Indian and Red seas; it is black, with scarcely any visible grooves.

PECTINATA. Shell longitudinally striate half way; one side fide flightly wrinkled tranfverfely. There is a variety of this fpecies. They are both found in the Indian ocean; the *firft* is about three inches long and four broad; the fhell is triangular, horny. The *fecond* is four and a half inches long, two and a half broad, thinner and more rare.

Nobilis. Shell ftriate, with fcales. There are four varieties of this fpecies. They are found in the Mediterranean, Adriatic, and American feas. The fhell of this fpecies is feven inches and a half long, and three and a half broad: it is brown, the exterior margin rounded; the fcales are larger towards the edges, and near half an inch long; one-half of the valves is ribbed, the other has tranfverfe wrinkles, which at the broader part are croffed with ftriæ.

* Muricata. Shell ftriate, with concave, ovate, acute fcales. This is defcribed and figured in Mr. Donovan's Britifh Shells; it is the P. fragilis of Pennant. It is a native of the European and Indian feas, is from three to nine inches long, and one-third as broad; the fhell is thin, brittle, pellucid, and horny; the outfide is formed with longitudinal ribs, rough with rows of fmall prickles.

Rotundata. Shell with obfolete fcales, the margin rounded. It inhabits the Mediterranean; it is fometimes above two feet long; the fhell is oblong, whitifh, with perpendicular, undulate, parallel wrinkles, and very fine, concave, acute, fcattered fcales on the broader part.

Squamosa. Shell with very fine undulate fcales, and flexuous broad wrinkles; the fmaller end is pointed and naked. It inhabits the Mediterranean, is about thirteen inches long, and half as broad. In colour it is a little chefnut at the larger end, and whitifh at the fmaller one; the external margin is angular.

Carnea. Shell thin, flefh colour, naked, longitudinally grooved; the external margin is acute and rounded. Its habitation is not known; it is fometimes varied with white fpots.

Succata. Shell fmooth, fatchel-fhaped, and a little erect. It inhabits the Mediterranean and Indian feas; is five and a half inches long, and half as broad; the fhell is thin, above it is reddifh, beneath whitifh, above flat, with a rounded margin, beneath gibbous, without fcales, but marked with ten broadifh, longitudinal ftriæ.

Digitiformis. Shell fmooth, tubular, finger-fhaped, incurved, the extreme margin membranaceous. It is a native of India. The fhell is flattifh, oblong, and pellucid.

Lobata. Shell naked, lobed. Found in India. The fhell is of a ftraw colour, with purple ftriæ, membranaceous and heart-fhaped when the valves are open. The lateral lobes rounded and broader, with a fort of nerve from the hinge to the lobes, and from the nerve there are lateral lines.

Vitrea. The fhell of this fpecies is hyaline, with longitudinal ftriæ, the ftriæ with a few fcales, are croffed by other tranfverfe ftriæ at the margin. It inhabits the Indian ocean, but is very rare.

Incurva. Shell narrow, long, naked, carinate, with tranfverfe undulate wrinkles. It inhabits the Indian ocean; pale horn colour, curved at the hinge, and marked with a few longitudinal ftriæ.

Bicolor. Shell thin, inflected at the lateral margin, yellowifh, with black-brown rays; with a few longitudinal ftriæ. It inhabits the Red fea. It is of a horn colour, long, with a few tranfverfe curved ftriæ at the margin, the larger end is rounded.

Exusta. Shell flattifh, horny, with blackifh rays, fpots, and clouds, and many fmooth ftriæ. It is rare, but fometimes found in the fouthern ocean of India.

Vexillum. Shell truncate at the outer margin, dilated, naked, horny, with a few black clouds; longitudinally ftriate on the fore-part, and tranfverfely wrinkled behind. It inhabits India, and is extremely rare. The fhell appears as if it were winged, with a curved lateral margin.

Papyracea. Shell very thin, brittle, horny, with longitudinal ribs, the extreme margin roundifh. This is a native of the Indian ocean: the back of the ribs is fometimes fcaly; in the middle of the fhell is a violet-brown fpot, and a few tranfverfe wrinkles at the lateral margin.

Sanguinea. Shell flattifh, and flightly incurved: it is red, with a few perpendicular fmooth ftriæ. The fhell is three inches long: it is probably a variety only of fome other fpecies.

Bullata. The fhell of this fpecies is very ftraight, thin and perpendicularly ftriate, with tranfverfe fpinous wrinkles at the lower margin. This, like the laft, is thought not to be a diftinct fpecies.

Pinna *Auris*, in *Anatomy*. See Ear.

Pinna *Nafi*, is the fame as ala nafi. See Nose.

PINNACE, a fmall veffel, navigated with fails and oars, and carrying generally two mafts; chiefly ufed as a fcout for intelligence, and for landing of men.

One of the boats belonging to a great man of war, ferving to carry the officers to and from the fhore, is alfo called the pinnace. It refembles a barge, but never rows more than eight oars, whereas a barge properly never rows lefs than ten. Pinnaces are for the accommodation of lieutenants, &c. as barges are for admirals, and captains of fhips of war.

PINNACLE, from *pinna*, or *pinnaculum*, in *Architecture*, the top or roof of a houfe, terminating in a point.

This kind of roof among the ancients, was appropriated to temples; their ordinary roofs were all flat, or made in the platform-way.

It was from the pinnacle, that the form of the pediment took its rife.

Pinnacle *Ifland*, in *Geography*, an ifland in the North Pacific ocean, fo named by Capt. Cook from the termination of its elevated fummit in feveral pinnacle rocks. N. lat. 60° 25′. E. long. 186° 40′.

Pinnacle *Point*, a cape on the S.E. coaft of Alafhka, fo called by Capt. Cook in 1778. N. lat. 55° 10′. E. long. 198° 5′.

Pinnacle *Iflands*, two fmall Japanefe iflands. N. lat. 29° 52′. E. long. 132°.

PINNÆ, *Aculei Pinnarum*, in *Ichthyology*. Every apophyfis, or eminence on the head or body of a fifh, which is fo fharp at the end as to be capable of pricking, is called an aculeus; but the aculei pinnarum in particular are thofe prickly radii or bones, which ferve to fupport the fins; and being carried out beyond the rim of the membrane, end in fo many points.

Thefe aculei are fimple cylindric officles; whereas the other officles, which fuftain the fins, are lefs rigid, and are bent and not prickly; and thefe are not fimple, but are compofed each of two officles, clofely cohering one to another. Many of thefe radii are divaricated at their extremity into two, three, or more branches; thefe, when they are carried out beyond the rim of the membrane, are harmlefs, and are feen to be compofed of two officles, as the body of the radius is. The aculei of the back and belly of all fifhes are fo far of the fame nature, that they never ftand fingle, as fome have fuppofed them to do in particular inftances; but they are always connected one to the other at the bottom by a membrane, though that be ever fo fmall and low, as in fome it is fcarcely vifible. See *Anatomy of* Fish.

PINNA-

PINNAMAQUAM, in *Geography*, a ſmall ſtream in Waſhington county, and ſtate of Maine, which gives name to a new ſettlement.

PINNARUM *Dilator Proprius*, in *Anatomy*, a name given by Santorini to one of the muſcles of the face, which he has alſo called myrtiformis naſi, and which Cowper has called depreſſor labii ſuperioris, ſive conſtrictor alæ naſi, and Albinus the depreſſor alæ naſi.

PINNARUM *Radii*. See RADII *Pinnarum*.

PINNATED LEAF, among *Botaniſts*. See LEAF.

PINNATIFID LEAF. See LEAF.

PINNATIPEDES, or *Fin-footed Birds*, in *Ornithology*, an order of birds, the characters of which are; that the bill, body, and mode of life reſemble thoſe of the waders or grallæ; the thighs are likewiſe naked for the lower half, and the feet are fitted for wading in marſhes, all the toes being divided; but the toes are edged on each ſide with a membrane for their whole length. Theſe birds moſtly live in pairs while breeding, and conſtruct very large neſts of various leaves and graſs in their marſhy haunts. The genera are *Phalaropus*, *Fulica*, and *Podiceps;* which ſee.

PINNATUS, in *Heraldry*, a term uſed by the Latin writers on theſe ſubjects, to expreſs that ſort of line in arms which is called by our heralds the embattled *line*, or *crenelle*. It is alſo called by ſome *linea pinnis aſperata*, and by Sylveſter Petro Sancto *murales pinnulæ*. When this line is only embattled on one ſide, it is properly expreſſed by this word; but when it is embattled on both ſides, as in ſome arms, it is called *breteſſe*, and *contre breteſſe*.

PINNAW, in *Geography*, a river which runs into the Elbe; 20 miles below Hamburgh.

PINNE, a town of the duchy of Warſaw; 24 miles W. of Poſen.

PINNEBERG, a town of the duchy of Holſtein, capital of a lordſhip; eight miles N.W. of Hamburgh. N. lat. 53° 43'. E. long. 9° 54'.

PINNEYRAH, a town of Hindooſtan; 12 miles N.N.W. of Benares.

PINNING, in *Building*, the faſtening of tiles together, with pins of heart of oak; for the covering of a houſe, &c.

PINNIRAPI, in *Antiquity*, an order of gladiators, who being matched with the Samnites, uſed to catch at the pinnæ which adorned their helmets, and bear them off in triumph, as marks of victory.

PINNOW, in *Geography*, a town of Hinder Pomerania; ſix miles N.E. of Plate.—Alſo, a lake of Brandenburg, in the Middle Mark, near Oranienburg.

PINOLA, or PINGOLA, a town of Mexico, in the province of Guatimala; 75 miles E. of Guatimala.

PINOLS, a town of France, in the department of the Upper Loire, and chief place of a canton, in the diſtrict of Brioude. The place contains 747, and the canton 3580 inhabitants, on a territory of 210 kiliometres, in nine communes.

PINOS, a town of Spain, in the province of Grenada; five miles E. of Grenada.—Alſo, an iſland near the S. coaſt of Cuba, reſembling a horſe-ſhoe in its figure, about 75 miles in circuit, mountainous and covered with pines. N. lat. 21° 32'. W. long. 82. 10'.

PINOS. See PINES.

PINOSA, a town of the iſland of May.

PINSHOWITZ, a town of Bohemia, in the circle of Leitmeritz; ſeven miles S. of Auſſig.

PINSK, a town of Ruſſian Lithuania, in the palatinate of Brzeſc, ſurrounded by moraſſes. Jews are numerous, and the Greeks have a biſhop; the chief manufacture is that of dreſſing Ruſſian leather; 84 miles E. of Brzeſc. N. lat. 52° 12'. E. long. 25° 53'.

PINSSON, FRANCIS, in *Biography*, a learned juriſt, ſon of a profeſſor of law of the ſame name, was born at Bourges in 1612. He was admitted an advocate in the parliament of Paris in 1633; but he was particularly diſtinguiſhed for his great knowledge of the law of benefices, in which he was regarded as the oracle, and which he illuſtrated by ſeveral learned works. Of theſe were "Traité des Benefices;" "La Pragmatique Sanction de St. Louis, et celle de Charles VII. avec Commentaires;" "Notes ſommaires ſur les Indults accordes à Louis XIV. &c.;" "Traités des Regales," 2 vols. 4to. which is ſaid to be a very learned and uſeful performance. This induſtrious writer died at Paris in 1691. Moreri.

PINT, PINTA, a veſſel or meaſure uſed in eſtimating the quantity of liquids, and even ſometimes of dry things.

Budæus derives the word pint from the Greek πινθα; others from the German *pint*, a little meaſure of wine; Nicod from the Greek πινειν, *to drink*.

The Engliſh pint is three-fold; the one for wine meaſure, another for beer and ale meaſure, and a third for dry meaſure.

The wine pint is ſaid to contain a full pound, avoirdupois, of common running water; two pints make a quart, two quarts a pottle, two pottles a gallon, &c.; a hogſhead is $8\frac{42}{100}$ cubic feet; a gallon 231 cubic inches; and a pint $28\frac{7}{8}$ cubic inches. See MEASURE, and TUN.

In the Engliſh ale and beer meaſure, the pint is the eighth part of a gallon, or 282 cubic inches; conſequently contains $35\frac{1}{4}$ cubical inches. See GALLON.

As to the pint uſed in Scotland, there are different opinions concerning the number of cubical inches it contains. Dr. Gregory makes them 109; others, from ſeveral careful menſurations of the ſtandard kept at Edinburgh, make the Scotch pint to contain $103\frac{4}{10}$; and thoſe in common uſe are ſaid to contain betwixt 105 and 106 cubical inches. Another experiment was made with a caſk, which was found to contain $46\frac{7}{8}$ Scotch pints, and $18\frac{1}{16}$ Engliſh ale gallons. Suppoſing this menſuration juſt, the Scotch pint will be to the Engliſh ale gallon as 289 to 750; and if the Engliſh ale gallon be ſuppoſed to contain 282 cubical inches, the Scotch pint will contain 108.664 ſuch inches. The Scotch pint, according to the ſtandard ſterling jug, is 103.404 Engliſh cubic inches: hence 105 Scotch pints = 47 Engliſh wine gallons, and 11 Scotch pints = 6 Engliſh ale gallons. The Scotch quart is commonly reckoned about $\frac{1}{10}$th leſs than the Engliſh wine gallon, and about $\frac{1}{4}$th leſs than the Engliſh ale gallon; and 1 pint = 2 choppins; and 1 choppin = 2 mutchkins; and 1 mutchkin = 4 gills. See MEASURE.

The Paris pint, according to the old ſyſtem, is eſtimated at one-ſixth of the ancient congius, and contains two pounds of common water, and is therefore nearly equal to an Engliſh wine quart; it is divided into chopines, which ſome call ſeptiers; the ſeptier into two demi-ſeptiers; the demi-ſeptier into two poiſſons, each poiſſon containing ſix cubic inches. Two pints make a quart, quarteau, which ſome call a pot: the pint of St. Denis is almoſt double that of Paris. See MUID.

At Genoa 100 pinte, wine meaſure, are equal to 2 barrili = a mezzarola = about 39 Engliſh gallons. For a compariſon of the liquid, &c. meaſures of different countries, ſee MEASURE.

PINTADO, or *Afra avis*, in *Ornithology*, a name given by the ancient Roman authors to the Guinea-hen. See NUMIDA; ſee alſo PROCELLARIA *Capenſis*.

PIN-TAIL, or *Anas Acuta*. See Duck.

PINTARD's Sound, in *Geography*, a bay on the W. coast of North America, the mouth of which extends from cape Scott on the southern side, in N. lat. 50° 56′, and W. long. 128° 57′, to Point Disappointment, in N. lat. 52° 5′, and W. long. 128° 50′: it contains many small islands.

PINTCHLUCO River, a large branch of the Chata Uche, the upper part of Appalachicola river.

PINTLE, in *Artillery*, a long iron bolt, fixed upon the middle of the limber bolster, to go through the hole made in the trail-transom of a field carriage, when it is to be transported from one place to another. The hole through which the pintle passes is wider above than below, in order to leave room for the pintle to play in.

Pintle-*Plate*, is a flat iron, through which the pintle passes, and nailed to both sides of the bolster, with eight diamond-headed nails.

Pintle-*Washer*, an iron ring, through which the pintle passes, placed close to the bolster for the trail to move upon.

Pintle, *Priest's*, in *Botany*. See Wake *Robin*.

Pintles, in *Ship Building*, straps of mixed metal or iron, fastened on the rudder in the same manner as the braces on the stern-post, into which they hang the rudder by a stout pin or hook at the fore end: thus the rudder turns or traverses as upon hinges, from side to side. Sometimes one or two are shorter than the rest, and work in a socket-brace, whereby the rudder turns easier. The latter are called *dumb-pintles*.

PINTO, Thomas, in *Biography*, an excellent performer on the violin, born in England of Italian parents. He was a miraculous player on his instrument when a boy; and long before manhood came on, was employed as the leader of large bands in concerts. He was, however, when Giardini arrived in England, very idle, and inclined more to the fine gentleman than the musical student; kept a horse; was always in boots of a morning, with a switch in his hand instead of a fiddle-stick. But after hearing Giardini, who was superior to all other performers on his instrument with which he was acquainted, he began to think it necessary to practise, which he did for some time with great diligence. With a powerful hand, and marvellous quick eye, he was in general so careless a player, that he performed the most difficult music that could be set before him, better the first time he saw it, than ever after. He was then obliged to look at the notes with some care and attention; but, afterwards trusting to his memory, he frequently committed mistakes, and missed the expression of passages, which, if he had thought worth looking at, he would have executed with certainty. After leading at the opera, whenever Giardini laid down the truncheon, he was engaged as first violin at Drury-lane theatre, where he led during many years. He married for his first wife Sybilla, a German under-singer at the opera, and sometimes employed in burlettas at Drury-lane. After her decease, he married the celebrated Miss Brent, and, quitting England, settled in Ireland, where he died in December 1782, aged 53 years.

His accuracy in playing at sight was so extraordinary, that he even astonished Bach and Abel by the extent of this faculty; and to embarrass him, if possible, they composed jointly a concerto for the violin, with solo parts as difficult as they could invent; and, carrying it to Vauxhall as soon as transcribed in separate parts, told him that they had just finished a concerto, of which, as it was somewhat out of the common way, they wished to hear the effects, if he would venture to try it at sight. "Let me see it," says Pinto; and after a slight glance at the solo parts, and picking his teeth in his usual way, he said if they pleased he would try it as his concerto for the night. And the eminent composers who wished to make this experiment, declared that they did not believe any of the greatest performers in Europe on the violin, would have played it better with a month's practice.

Pinto, who in playing an adagio seemed to have so much feeling and expression, was a Stoic at heart, equally indifferent to pain and pleasure. While he led the band at Drury-lane, during the most affecting scene of Garrick's capital tragic parts, he used to fall asleep in the orchestra full in his view, which, after our *genuine* Roscius had with indignation seen, he never rested till his place in the orchestra was supplied with a leader on whose feelings he had more power. Indeed, we remember a more ridiculous mortification happening to our ever-to-be-lamented friend, Garrick, from a centinel at one of the stage doors, equally destitute of human feelings with Pinto, yawning aloud during the deepest distress of king Lear, which so completely turned "what should be great, to farce," that the vulgar part of the audience, being cocknies, burst into a loud *horse-laugh*; which so disconcerted and enraged the good old king, that he complained to the captain of the guard, and begged that so impenetrable a centinel might never be placed again on the stage to make the audience laugh, whilst he was doing every thing in his power to make them cry.

Pinto died with the same indifference about worldly concerns as he had lived, and left his unfortunate widow, the once much famed Miss Brent, so literally a beggar, that she returned to England to solicit charity from the Musical Fund; which, alas! she did in vain: for by his having during several years neglected to pay his subscription, all her claims were annihilated in an establishment which she and her husband had often by their gratuitous performance contributed, at its annual benefits, to support, previous to its being enriched, and rendered a royal institution by the commemoration of Handel.

Pinto, in *Geography*, a town of Spain, in New Castile; 9 miles S. of Madrid.

PINTRAL, a town of Hindoostan, in the Carnatic; 26 miles S. of Ongole.

PINTURICCIO, Bernardino, in *Biography*, was born at Perugia in 1454, and was a disciple, and for some years associate, of Pietro Perugino. He painted in history and portraits, and was in so much esteem, that he was employed to paint the portraits of pope Pius II., and of Innocent VIII; of Giulia Farnese, Cæsar Borgia, and queen Isabella of Spain. His style, nevertheless, was extremely dry and Gothic, as he introduced gilding in the architectural and other parts of his pictures, and an overlaboured degree of finishing.

In his most memorable performance, the history of Pius II., painted in ten compartiments in the library at Sienna, he is said to have been assisted by Raphael, then a very young man, and pupil of Perugino, who made some cartoons of the most material incidents, and sketched many parts of the compositions.

His last work was a Nativity for the monastery of St. Francis at Sienna; in which place he had a room assigned him to paint in, without the danger of his being interrupted; and out of which he requested every thing might be removed. Willing to indulge him, the monks caused all the furniture to be taken away, except an old chest, which, being greatly decayed, they did not attempt to move, as they were fearful of destroying it. Pinturiccio insisted, however, upon its removal; and the attempt was scarcely

ſcarcely made, when it broke to pieces, and a treaſure of 500 pieces of gold was diſcovered concealed within it.

The joy of the monks was equalled only by the mortification of the painter, who was ſaid to have died of chagrin ſoon after, at the age of 59.

PINTZOUA, in *Geography*, a town of Pruſſia, in the province of Pomerelia; 22 miles S.S.W. of Marienburg.

PINUS, in *Botany*, the fir, cedar, larch, &c. a moſt important and well-known genus of plants, two points in whoſe hiſtory have, neverthelefs, been involved in great obſcurity; theſe are the derivation of the generic name, and the nature and ſituation of the ſtigma of the flower. Linnæus places *Pinus* amongſt ancient Latin names of unknown origin; and Martyn, like Ambroſinus, leaves it unexplained. The lexicographers are moſtly content to refer to its Greek ſynonym πίτυς; and it is poſſible that both words had the ſame ſource. De Theis deduces *Pinus*, very ſatisfactorily, from the Celtic, and ſhews it to exiſt, variouſly modified, in all the dialects of that ancient language, its baſis being *pin* or *pen*, a mountain or rock; whence we have the Apennines; the Pennine Alps, &c. The Gallic *pinwidden*, like the German *pyn-baum*, means preciſely a mountain tree; than which nothing can be more appropriate. Of the ſtigma we ſhall treat in its proper place.—Linn. Gen. 499. Schreb. 651. Willd. Sp. Pl. v. 4. 494. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1031. Ait. Hort. Kew. v. 5. 314. Juſſ. 414. Tourn. t. 355, 356. Lamarck Illuſtr. t. 786. Michaux Boreal-Amer. v. 2. 204. Purſh North Amer. v. 2. 639. Gærtn. t. 91. (Abies; Juſſ. 414. Tourn. t. 353, 354. Lamarck Illuſtr. t. 785. Larix; Tourn. t. 357.)—Claſs and order, *Monoecia Monadelphia*. Nat. Ord. *Coniferæ*, Linn. Juſſ.

Gen. Ch. Male, *Cal.* none, except the ſpreading ſcales of the flower-bud. *Cor.* none. *Stam.* Filaments very numerous, collected below into a cylindrical column, racemoſe above; anthers horizontal, wedge-ſhaped, opening underneath by two longitudinal cells, and crowned by an aſcending membranous creſt.

Female, on the ſame plant. *Cal.* a nearly ovate denſe catkin, compoſed of oblong, cloſely imbricated, wedge-ſhaped, rigid, permanent, two-lipped ſcales. *Cor.* none. *Piſt.* Germens two at the baſe of each ſcale; ſtyle none; ſtigmas between the lips of the ſcale. *Peric.* none, except the hardened ſcales, combining to form a woody permanent cone. *Seeds* two to each ſcale, each lodged in a little hollow at the baſe, oval, furniſhed with a vertical, membranous, unequal-ſided wing, uſually larger than the ſeed, but ſmaller than the correſponding half of the annexed ſcale.

Eſſ. Ch. Male, Calyx none. Corolla none. Anthers racemoſe, creſted.

Female, Calyx the ſcale of a catkin, unequally two-lipped. Corolla none. Cone woody. Seeds two, winged at the baſe of each ſcale.

Obſ. Linnæus deſcribes as the ſtyle and ſtigma, the awl-ſhaped point, which terminates one lip of the ſcales of the female catkin, and, in ſome ſpecies, hardens into a very powerful ſpine. Juſſieu deſcribes in his *Abies*, which includes the larches and ſpruce firs, two glands like ſtigmas at the baſe of one of the ſcales, or rather, as we underſtand the flower, one of the lips of each ſcale. An examination of ſeveral ſpecies has perſuaded us that the impregnation takes place nearly as this great writer's account implies, and poſſibly, in ſome meaſure, as Mr. Saliſbury has explained, in Tr. of the Linn. Soc. v. 8. 309; though we ſuſpect ſome error as to the Larch, and particularly thoſe "long crimſon ſtigmas" of the *P. Cembra*, there deſcribed. —The knowledge of the ſpecies of this genus, and their various uſeful properties, has been greatly augmented by the magnificent and learned monograph of Mr. Lambert, publiſhed in 1803. Linnæus has defined but twelve ſpecies; Mr. Lambert deſcribes thirty-four, of which thirty are enumerated by Mr. Aiton in the new edition of his Hortus Kewenſis; Mr. Purſh has nineteen in his Flora of North America, juſt come to our hands. Thoſe which are the produce of that country have received the moſt complete botanical inveſtigation. The oriental ones are not, as yet, ſo well underſtood, nor are they, apparently, by far ſo numerous.—The younger Michaux in his *Arbres foreſtiers*, a work in three volumes 8vo., has, it ſeems, criticiſed inaccurately much of Mr. Lambert's work, and very unwarrantably changed ſome of his names. Theſe attacks are repelled by our intelligent friend, in Mr. Purſh's work, publiſhed under his inſpection. Our ſections are thoſe of Mr. Lambert.

Sect. 1. *Leaves ſeveral from the ſame ſheathing baſe.* Pinus of Tournefort. Nineteen ſpecies.

1. P. *ſylveſtris.* Scotch Fir. Linn. Sp. Pl. 1418. Willd. n. 1. Ait. n. 1. Lambert 1. t. 1. Engl. Bot. t. 2460. Mill. Illuſtr. t. 82. Woodv. Med. Bot. t. 207. Ger. Em. 1356.—Leaves in pairs, rigid. Young cones ſtalked, recurved. Creſt of the anthers very ſmall.—Native of dry ſtony ſandy hills in Scotland, and other northern parts of Europe, flowering in May, and ripening ſeed two years afterwards. This ſpecies lives to the age of 400 years or more, and is lofty and ſtraight in its growth, with oblique *branches*. The *bark* ſcales off in large light cellular flakes. *Sheaths* of the leaves ſpirally diſpoſed, tubular, membranous, at length rugged, torn at the end. *Leaves* in pairs from each ſheath, equal, about two inches long, linear, narrow, obtuſe with a ſmall point, minutely ſerrated, evergreen, ſmooth; their upper ſurfaces, which are dark green, and rather concave, originally clapped together, but ſoon ſeparating; the under convex, more glaucous, ſtriated. *Flowers* terminal, erect; the males aggregate, ſpiked, ſulphur-coloured, ſoon ſurmounted by a protruding leafy branch, each flower having ſeveral chaffy concave ſcaly *bracteas* at its baſe, which ſome call a four-leaved *calyx*: females ſolitary, globular, variegated with purple and green, with ſeveral ſerrated, pointed, ſcaly *bracteas*. The year after impregnation, the young *fruit* becomes lateral, ſtalked and reflexed, green, of a more ovate figure; and the ſecond year ripens into ovate, pointed, hard, teſſellated but unarmed, woody *cones*, whoſe dry ſcales finally gape, and allow of the diſperſion of the winged *ſeeds*. This is further promoted, in various ſpecies, by the attacks of *Loxiæ*, and ſuch hard-billed birds, who in ſeeking the ſeeds for food, ſplit the cone, thus diſperſing many more ſeeds than they devour. The wood of *P. ſylveſtris* is known by the name of red deal, and its value, as well as that of the tar, pitch, and turpentine, afforded by this ſpecies, is well known. The *tree* is planted on our moſt barren expoſed hills and downs, as a ſhelter for more tender plantations, and is in itſelf a profitable object of culture, though not one of the moſt agreeable ornaments to a country where any thing elſe will grow. We have obſerved with regret ſome noble beech woods in Berkſhire, recently bordered with miſerable Scotch and ſpruce firs, which happily indeed ſoon die in that chalky ſoil, and the miſchief is neither laſting nor extenſive.

P. Mughus, Jacq. Ic. Rar. t. 193. Willd. n. 2, is judged by Mr. Lambert to be a variety of *ſylveſtris*, of a humble ſpreading growth, cauſed probably by its lofty ſtation on the alps of Auſtria; nor is it, as Jacquin thought, the *Mughus* of Scopoli; ſee the next ſpecies.

2. P. *Pumilio.* Mugho, or Mountain Pine-tree. Willd. n. 3.

n. 3. Ait. n. 2. Scop. Carn. v. 2. 247. Lamb. 5. t. 2. (Pinaſter Pumilio; Cluſ. Pann. 15. P. quartus auſtriacus; Cluſ. Hiſt. v. 1. 32. Ger. Em. 1358.)—Leaves in pairs, ſhort, ſtraight. Cones ovate, obtuſe, very ſmall; the younger ones ſeſſile, erect. Creſt of the anthers prominent, cloven.—Native of mountains in the ſouth-eaſt parts of Europe, flowering in June. Mr. Blackburne of Orford is recorded as its firſt cultivator in England. This, the moſt humble of its genus, is ſcarcely ſeven feet high, extending itſelf by trailing *ſhoots*, and even by rooting decumbent *branches*. The *leaves* are ſhorter, and *cones* much ſmaller than the foregoing, and the much more diſtinct, prominent, two-lobed, crenate creſt of the *anthers*, affords a ſatisfactory mark of ſpecific diſtinction.

3. P. *pungens*. Prickly-coned Pine-tree. Lamb. 91. t. 16. f. *c*, the cone only. Ait. n. 3. Purſh. n. 14. Mich. Arb. For. v. 1. 61. t. 5. *Ait.*—Leaves in pairs, ſhort, acute. Cones ovate; the prickles of their ſcales elongated, very ſharp, incurved; the lower ones deflexed.—Native of the ſummits of the blue mountains on the frontiers of Virginia and North Carolina, in large foreſts, where it was found by W. Strickland, eſq. The *leaves* are much broader and ſhorter than thoſe of *P. Pumilio*, and tipped with a ſpinous point. *Cones* broad-ovate, light tawny brown, armed with extremely pungent incurved ſpines.

4. P. *Bankſiana*. Labrador Pine-tree. Lamb. 7. t. 3. Ait. n. 4. Willd. n. 10. Purſh n. 10.—Leaves in pairs, divaricated, oblique. Cones recurved, twiſted. Creſt of the anthers dilated, emarginate.—Native of Nova Scotia, Hudſon's Bay, &c. Rarely cultivated in England, flowering in April. This is with us a tall *tree*, with numerous long and ſpreading *branches*, though more humble on its native rocks. *Leaves* ſcarcely above an inch long, variouſly twiſted. Creſt rather broader than the *anther* itſelf, kidney-ſhaped, emarginate and crenate. *Cones* very abundant, oblong, rather ſlender, rugged, brown, two inches in length, recurved, ſo that their points touch the branch, and often meet each other. Communicated to Mr. Lambert by ſir J. Banks. The fineſt trees of this ſpecies are in the gardens at Pain's-hill and Kew.

5. P. *Pinaſter*. Cluſter Pine-tree. Ait. H. Kew. ed. 1. v. 3. 367. Lamb. 9. t. 4, 5. Ait. n. 5. Willd. n. 4. (P. maritima altera; Matth. Valgr. v. 1. 91. Duham. Arb. v. 2. 125. t. 29.)—Leaves in pairs, elongated. Cones whorled, cluſtered, ovate, ſeſſile, drooping, with ſomewhat pointed ſcales. Creſt of the anther rounded.—Native of the ſouth of Europe, in rocky mountainous places, eſpecially near the ſea. Common in Engliſh plantations, flowering in April and May. Larger in every part than the Scotch fir, forming a ſtout and lofty *tree*. The *leaves* are four inches long, narrow, pungent, ſtraight. The male *flowers* compoſe a very handſome golden thyrſus; the creſt of their *anthers* is rounded, nearly orbicular, crenate; not *dilated*, as Willdenow has erroneouſly copied Mr. Lambert, which has cauſed a ſimilar error in Hort. Kew. Female *flowers* with rich crimſon ſcales. *Cones* ovate, rather pointed, four inches long, bright brown, each ſcale tipped with a ſhort broad bluntiſh ſpine. In the ſouth of France theſe trees are waſtefully cut all down one ſide, as they ſtand, in winter, for the turpentine to ooze out. The wood and pitch is much uſed in Switzerland. The ſtakes ſerve to ſupport vines of humble growth.

6. P. *Pinea*. Stone Pine-tree. Linn. Sp. Pl. 1419. Lamb. 11. t. 6, 7, 8. Willd. n. 11. Ait. n. 6. (P. domeſtica; Matth. Valgr. v. 1. 87. P. ſativa; Duham. Arb. v. 2. 125. t. 27. Ger. Em. 1355.)—Leaves in pairs. Cones ovate, obtuſe, as long as the leaves; their ſcales with recurved deciduous points. Seeds bony, with very ſhort wings. Creſt of the anthers jagged.—Native of the ſouth of Europe and north of Africa. Mr. Hawkins and Dr. Sibthorp obſerved it in Greece, eſpecially in the ſandy plains of Elis, from whence the nuts are exported for eating, and the timber is often uſed for ſhip-building. In Italy theſe nuts generally ſupply the place of almonds, in various articles of cookery; and that they have done ſo from remote antiquity, appears from their having been found among the domeſtic ſtores in the pantries of Herculaneum and Pompeia. The kernel is ſweet, with a turpentine flavour; its ſhell very hard. This *tree* appears to great advantage in the landſcapes and gardens about Rome, as well as occaſionally in our Engliſh plantations. Its fine dark green *leaves*, copious male *bloſſoms* diffuſing a ſhower of ſulphureous pollen on all the neighbouring plants, and the maſſy *cones*, render it very remarkable.

7. P. *maritima*. Maritime Pine-tree. Lamb. 13. t. 10. Willd. n. 8. Ait. n. 7.—Leaves in pairs, ſlender, rough-edged. Cones ovate, ſolitary, drooping, ſtalked, teſſellated, even, cloſe. Creſt of the anthers ſomewhat pointed, undivided.—Native of the ſea-coaſts of the ſouth of Europe. Micheli ſent a ſpecimen to Sherard from Italy, and Dr. Sibthorp gathered the ſame in Greece, as we learn from his collection of drawings. Miller appears to have cultivated this ſpecies, but we feel ſome ſlight doubts reſpecting Mr. Lambert's ninth plate, and his cone from Sion gardens, t. 10. f. f, is ſurely different. The *cones* of the true *maritima* are peculiar for their even or level ſurface, the outer part of each ſcale being flat, with a central ſcar, which has no point nor prominence; nor do they ſpread or ſeparate much to diſcharge the ſeeds. The male *flowers* are capitate, not ſpiked; they are ſhorter and the creſt of their *anthers* leſs orbicular, and more pointed, in Dr. Sibthorp's figure than in Mr. Lambert's t. 9, though both drawings were made by the ſame excellent artiſt; and their capitate infloreſcence agrees.

8. P. *halepenſis*. Aleppo Pine-tree. Lamb. 15. t. 11. Willd. n. 7. Ait. n. 8. Desfont. Atlant. v. 2. 352. Mill. Ic. t. 208. (P. maritima prima; Matth. Valgr. v. 1. 90.)—Leaves in pairs, very ſlender. Cones ovate-oblong, drooping, ſtalked, tuberculated, poliſhed, unarmed. Creſt of the anthers rounded, jagged.—Native of Syria. Obſerved by Desfontaines alſo on mount Atlas, and on the uncultivated hills of Barbary, abundantly, as well as in the ſouth of France near Frejus; but this tree does not always bear the winters of Paris nor of London, ſo that it is very ſcarce in collections. It differs from the laſt in having more ſlender *leaves*; ſpiked male *flowers*, the creſt of whoſe *anthers* is broader than long, jagged, not pointed; and eſpecially in the ruggedneſs of its cones, the prominent part of whoſe ſcales is tumid, and of a fine poliſhed red-brown. Theſe ſcales ſpread widely to diſcharge the ſeeds. The ſynonym of Matthiolus is given on the authority of a ſpecimen ſeen by Mr. Lambert in the Sherardian herbarium; and indeed his cut anſwers well to our plant, though employed by Duhamel, v. 2. t. 28, for his own P. maritima major, inſtead of his P. hieroſolymitana, &c. n. 14, to which we preſume it belongs.

9. P. *Maſſoniana*. Indian Pine-tree. Lamb. 17. t. 12. Willd. n. 9.—Leaves in pairs, very long and ſlender; their ſheaths very ſhort. Creſt of the anthers ſhort, broad, toothed.—Native of China; from whence its ſeeds were brought to the Cape of Good Hope, and produced flowering trees there, ſpecimens of which, given to ſir J. Banks by Mr. Maſſon, were examined and delineated for Mr. Lambert's work, nor has this ſpecies been elſewhere publiſhed.

liſhed. The *ſtipulas* on the young ſhoots are finely fringed. *Leaves* four or five inches long, apparently erect. Male *flowers* ſpiked; the creſt of their *anthers* twice as broad as long, ſharply toothed. The *cones* have not come to our knowledge.

10. P. *inops*. Jerſey Pine-tree. Ait. Hort. Kew. ed. 1. v. 3. 367. Lamb. 18. t. 13. Willd. n. 5. Ait. n. 9. Purſh. n. 8. Michaux Arb. For. v. 1. 58. t. 4.—Leaves in pairs. Cones drooping, oblong-conical, longer than the leaves; their ſcales with awl-ſhaped prominent ſpines. Creſt of the anthers ſhort, broad, jagged.—Native of dry barren hills, in the interior parts of North America, from New Jerſey to Carolina, where it bloſſoms in May. Mr. Purſh ſays it is of a middle ſize, ſtraggling growth, and full of reſin, the branches tougher than any other pine with which he is acquainted. It might ſerve for ſeveral uſeful purpoſes, if the wood were not ſo liable to early decay. This account agrees with Mr. Lambert's, which M. Michaux has controverted. Kalm has remarked that cattle in hot weather ſtudiouſly ſingle out this tree for ſhade in preference to all others. Its effluvia are ſuppoſed to be agreeable to them; or rather perhaps hoſtile to ſome inſects which perſecute them, ſuch as gad-flies, to whoſe approach all cattle are extremely ſenſible. See Linn. Tour in Lapland, v. 1. 205. The *leaves* of *P. inops* are of a dark green, two inches long, leſs ſlender than in *maritima* or *halepenſis*, the aſpect of the tree being moſt like a ſtarved Scotch Fir. The ſcales of the female *catkin* are reddiſh, with long taper points, that harden into pungent, prominent, ſlightly curved ſpines on the ripe *cone*.

11. P. *reſinoſa*. American Pitch Pine-tree. Red Pine. Ait. H. Kew. ed. 1. v. 3. 367. Lamb. 20. t. 14. Willd. n. 6. Ait. n. 10. Purſh n. 9. (P. rubra; Michaux Arb. For. v. 1. 45. t. 1.)—Leaves in pairs, elongated, with long ſheaths. Cones ovate, ſeſſile, nearly ſolitary, tolerably even, unarmed, not half the length of the leaves. Creſt ſhort, jagged, narrower than the anther.—Native of Canada and the weſtern parts of New York. *Purſh*. It was firſt raiſed in England by the late duke of Northumberland, at Sion Houſe, where many of this ſpecies are ſtill to be ſeen, flowering in May. This tree requires, according to Mr. Lambert, a moiſt ſituation, and light ſandy ſoil, and though rare in England, is well worthy of cultivation, being of elegant appearance, and remarkable for the fragrance and abundance of its reſin. The *leaves* are four inches long, roughiſh at the point, ſpreading, with ſheaths a quarter of their length. Male *flowers* ſpiked, copious, handſome, the creſts of their *anthers* purple. Female *flowers* oval, deep purple, their ſcales broad, the larger lip only very ſlightly pointed. *Cones* uſually two or three together, ſeſſile, ſpreading, ſcarcely half the length of the leaves, ovate, obtuſe, their ſcales a little tumid, but quite deſtitute of ſpines or points. In cloſe foreſts, Mr. Purſh ſays, this ſpecies grows very tall, with a remarkably ſmooth red bark. The timber is very heavy, and therefore unfit for maſts.

12. P. *variabilis*. Two and three-leaved Pine-tree. Yellow Pine. Lamb. 22. t. 15. Willd. n. 12. Ait. n. 11. Purſh n. 11. (P. mitis; Michaux Arb. For. v. 1. 52. t. 3.)—Leaves two or three together, channelled with ſhort ſheaths. Cones oblong-ovate, nearly ſolitary, ſtalked, drooping; their ſcales with ſhort inflexed ſpines. Found in moſt pine foreſts, from New England to Georgia. *Purſh*. Mr. Lambert has ſeen but two trees of this kind in England, one at Pain's hill, the other at Kew; nor has he delineated the male flowers. This author ſpeaks of the wood as too ſpongy and light to be durable; but Mr. Purſh ſays "the yellow pine is the moſt in uſe for building of houſes as well as ſhipping." The diverſity of number among the *leaves* on the ſame branch is peculiar. Their length, almoſt two inches, rather exceeds that of the *cones*. Their *ſheaths* are ſhort.

13. P. *Tæda*. Frankincenſe Pine-tree. Linn. Sp. Pl. 1419. Willd. n. 14. Ait. n. 13. Purſh n. 15.—Leaves three together, elongated, with long ſheaths. Cones ovate-oblong, deflexed; their ſcales with inflexed ſpines. Creſts of the anthers imbricated, orbicular.—Native of barren ſandy ſituations, from Virginia to Florida. Mr. Purſh ſays this, which he terms the Loblolly, or Old-field Pine, "is found in large tracts in the ſouthern ſtates. All the woods ſeem to be ſeeded with it; for when any piece of cleared land is neglected, for any ſpace of time, it will be covered with thoſe pines. It is difficult, and in ſome caſes almoſt impracticable, to recover thoſe lands run over with young pines, as the ground appears to have loſt all fertile properties for any other vegetable than thoſe trees." The *leaves* are three from each ſheath, larger, and their *ſheaths* longer, than even in *P. reſinoſa*. Male *flowers* capitate, of a glowing yellow, the creſts of their *anthers* orbicular and crowded, or imbricated, over each other. The length of the *leaves* is about ſix inches; that of the *cones* about three. Their *ſpines* are very ſharp, broad at the baſe, ſhort, all inflexed. *Fig. c* of Mr. Lambert's t. 16, we have already cited as another ſpecies; ſee *pungens*, n. 3. His reference to Wangenheim, and the obſervations borrowed from that author, are alſo miſplaced here, belonging rather to *rigida* or *ſerotina*, in Mr. Purſh's opinion. *P. Tæda* flowers in America about April or May. It would be well worthy of cultivation in England, on barren ſandy heaths, where nothing elſe of value will thrive; but though it has been known above a century in our gardens, nobody ſeems to have taken up this ſpecies as an object of ornament or economy.

14. P. *rigida*. Three-leaved Virginian Pine-tree. Common American black, or pitch, pine. Mill. Dict. ed. 8. n. 10. Lamb. 25. t. 18, 19. Willd. n. 13. Ait. n. 13. Purſh n. 12. Michaux Arb. For. v. 1. 89. t. 8.—Leaves three together, elongated, with ſhortiſh ſheaths. Cones cluſtered, ovate; their ſcales with reflexed ſpines. Creſt of the anthers rounded, jagged. Found in the plains, from New England to Virginia, either in dry, or wet low ſituations, bloſſoming in May. *Purſh*. It often grows to a large ſize. The numerouſly cluſtered *cones* afford a ſtriking character at firſt ſight. The *leaves* are about three or four inches long, rough at the points; their *ſheaths* of a much ſhorter proportion than thoſe of *P. Tæda*. The ſpines of the *cones* being reflexed, not inflexed, will, at any time, diſtinguiſh them. The wood is not excellent.——*P. ſerotina*; Mich. Boreal-Amer. v. 2. 205. Mich. Arb. For. v. 1. 86. t. 7. Willd. n. 16. Purſh n. 13, of which a cone is given in Lambert's t. 19. f. 5; P. Tæda δ; Ait. H. Kew. ed. 1; the β of the 2d edition; appears, by Mr. Purſh's account, to be but a variety of the *rigida*, growing on the edges of ponds and ſwamps.

15. P. *paluſtris*. Swamp Pine-tree. Long-leaved, or Broom Pine. Mill. Dict. ed. 8. n. 14. Lamb. 27. t. 20. Willd. n. 15. Ait. n. 14. Purſh n. 16. Sm. Abb. Inf. v. 1. 83. t. 42. (P. auſtralis; Mich. Arb. For. v. 1. 64. t. 6.)—Leaves three together, very long, drooping, with long ſheaths. Stipulas pinnatifid, reflexed, permanent. Cones ſomewhat cylindrical, prickly.—Native of foreſts near the ſea coaſt, from North Carolina to Florida. *Purſh*. Seldom ſeen in our gardens, except of a very ſmall ſize, being tender. A tree at Kew, with its copious drooping *leaves*, 12 or 15 inches long, makes a beautiful appearance. The male *flowers*, which Mr. Lambert was obliged to have drawn from a dried American ſpecimen, are capitate, very long.

long, with imbricated orbicular tawny crefts to the *anthers*. *Cone* 10 or 12 inches long, each fcale tipped with a fmall, prominent, rather incurved, fpine. The points of the *leaves* are finely ferrated; their *fheaths* long, fplitting at the top into linear, recurved, jagged fegments. *Stipulas* at the bafe of the fheaths, and not half fo long, linear, recurved, acute, torn in a pinnatifid manner.

16. P. *longifolia*. Long-leaved Pine-tree. Lamb. 29. t. 21. Willd. n. 17. Ait. n. 15.—Leaves three together, very long and flender, drooping, finely ferrated, with long fheaths. Stipulas entire, deciduous. Cones ovate, with prominent, angular, recurved, minutely-fpinous fcales.—Native of the lofty mountains of Nepaul, in the Eaft Indies, where, according to Dr. Roxburgh, this *tree* grows to the height of 100 feet, bloffoming about the beginning of the hot feafon. It is marked as a green-houfe plant in Hort. Kew. and faid to have been introduced by Meffrs. Gray and Wear, in 1801. Nothing can be more beautiful than the copious tuft of flender, pendulous, rough-edged *leaves*, near 18 inches long, as exhibited in Mr. Lambert's beautiful plate. The male *flowers* are rather capitate than fpiked. *Cones* (of which a folitary perfect fpecimen is given in a fecond impreffion of that plate, inftead of two which prove to belong to a different and undefcribed fpecies, fee p. 91,) ovate, four inches long, diftinguifhed by the unufually prominent recurved points of their *fcales*. The head of this lofty *tree* is faid to be round and fmall, affording little fhade.

17. P. *Strobus*. Weymouth Pine-tree. Linn. Sp. Pl. 1419. Willd. n. 20. Ait. n. 16. Purfh n. 17. Lamb. 31. t. 22. (P. americana, quinis ex uno folliculo fetis, &c.; Hort. Angl. 57. t. 17. f. 1.)—Leaves five together. Cones cylindrical, imbricated, fmooth, longer than the leaves. Creft of the anthers of two minute awl-fhaped briftles. Found on the fides of hills, in a fertile foil, from Canada to Virginia, flowering in May. It is the largeft and moft ufeful of all the American Pines, and the beft timber for mafts, growing, in the ftate of Vermont, to an enormous fize. *Purfh*. The attention which lord Weymouth, afterwards marquis of Bath, gave to the cultivation of this valuable tree, has juftly ftamped it with his name. It is now generally diffufed through every confiderable plantation. Its timber is excellent. The *leaves* are very flender, and differ from all the preceding in growing five from each fheath. In winter they approach the branch in an erect pofture; in fummer they fpread widely. The male *flowers* are diftinguifhed by the peculiar creft of their *anthers*. The long, taper, fmooth, deflexed *cones*, with broad flat fcales, are very peculiar, and, in a green unripe ftate, fingularly elegant.

18. P. *Cembra*. Siberian Stone Pine-tree. Linn. Sp. Pl. 1419. Willd. n. 18. Ait. n. 17. Lamb. 34. t. 23, 24. Pall. Roff. v. 1. 3. t. 2. (P. maritima altera; Matth. Valgr. v. 1. 93. P. n° 30; Gmel. Sib. v. 1. 179. t. 39. P. n. 20; Duham. Arb. v. 2. 127. t. 32. P. fylveftris, cembro; Camer. Epit. 42.)—Leaves five together. Cones ovate, imbricated. Wing of the feeds obliterated. Creft of the anther kidney fhaped, crenate. Native of the alps of Siberia, Tartary, Switzerland, Italy, &c. In Switzerland it is known by the name of Aphernoufli. Mr. Aiton records it to have been cultivated in 1746, by Archibald, duke of Argyle. Being of extremely flow growth, only very fmall plants of this fpecies are ufually feen in collections. The fineft we have obferved were at Mill Hill; but after the deplorable havock made there by ignorant or negligent poffeffors, we know not whether thefe trees ftill exift. (See COLLINSON.) They were fuppofed to be fixty or feventy years old in 1802, when we faw them in fine flower and fruit, being then but juft arrived at the vigour of their growth, and by no means at full maturity. The afpect of the *tree* is not very handfome. The *leaves* are of a dull hue, fine and flender like the Weymouth pine, with which they agree in number. Male *flowers* copious, capitate; the *anthers* and their rounded crefts tipped with purple. *Cones* ovate, thick, two inches or more in length, purplifh, with a plum-like bloom; their fcales thick, obtufe, with a fomewhat corky furface. *Seeds*, which we have never feen perfected in England, almoft deftitute of a wing, obovate, refembling thofe of *P. Pinea*, like which they are eatable; but their fhell is more eafily broken.

19. P. *occidentalis*. Weft Indian Pine-tree. Swartz Ind. Occ. v. 2. 1230. Lamb. 36. Willd. n. 19. (P. foliis quinis ab eodem exortu; Plum. Ic. 154. t. 161.)—Leaves five together, rough-edged, very long. Cones ovate, teffellated, fhorter than the leaves; their fcales minutely fpinous. Wing longer than the feed.—Native of the mountains of Hifpaniola, according to Dr. Swartz, who never faw more than one tree of this fpecies, and a nearly deftroyed *cone*. He defcribes it as fifty feet or more in height, with upright uneven rugged *branches*. *Leaves* crowded about the extremities of the branches, five from each fheath, a fpan long, linear-awlfhaped, triangular, with rough, or finely ferrated, edges. *Cones* three inches long, deflexed. Plumier's figure agrees with this account, but it very diftinctly fhews the cone to be not, as Swartz fubfequently fays, imbricated, but teffellated like moft of the firft-defcribed fpecies, each fcale having an abrupt angular termination; whereas in *P. Strobus* and *Cembra*, the only two fpecies befides that have five leaves from one fheath, the fcales of the *cones* are truly imbricated over each other. The *feeds* moreover being, as far as we can judge from Plumier's plate, confiderably winged, differ widely from thofe of *Cembra*; as the whole *cone* does from that of *Strobus*, to which latter fpecies Burmann, the editor of Plumier, moft incautioufly referred his plant.

Sect. 2. *Leaves folitary, fcattered.* ABIES of Tournefort. Eleven fpecies.

20. P. *Abies*. Norway Spruce Fir. Linn. Sp. Pl. 1421. Willd. n. 32. Ait. n. 18. Lamb. 37. t. 25. Fl. Dan. t. 193. Woodv. Med. Bot. t. 208. (Picea; Matth. Valgr. v. 1. 88. Camer. Epit. 47. P. major; Ger. Em. 1354.)—Leaves folitary, quadrangular. Cones cylindrical; their fcales rhomboid, flattened, waved and notched. Common filament fhorter than the bracteas.—Native of mountains in various parts of Europe, as well as the north of Afia, in places watered by alpine rills, where it grows to a lofty height, and makes a magnificent appearance. Though not a native of this ifland, few trees have been more generally or longer cultivated here; its ftately though formal growth, and efpecially the fine colour of its evergreen leaves, rendering it very ornamental. The wood is alfo one of the moft valuable forts of deal, and the forefts of Norway afford it abundantly. Mr. Lambert however informs us, that what is grown in England is moft durable, and particularly efteemed for making ladders. Burgundy pitch is prepared from this fpecies. The height of the tree is from 100 to 150 feet. It flowers in April. The long fweeping fan-like branches, often broken down by loads of fnow, and the effect of boifterous winds, have a grand effect in alpine landfcapes, and have been well employed in the fublime compofitions of Salvator Rofa, and the German engravers. The *leaves* are copioufly fcattered all round the branches, afcending, fomewhat imbricated, each fcarcely an

an inch long, on a ſhort ſtalk, ſmooth, linear, curved, bluntiſh, with four rather unequal angles, and as many intermediate hollows. *Stipulas* none. *Flowers* terminal; the males moſt plentiful, of a tawny red; their *bracteas* numerous, ſpreading, longer than the common filament or baſis of the *ſtamens;* anthers yellow, their creſt crimſon, roundiſh kidney-ſhaped, deeply and acutely jagged. Female *catkins* ſeſſile, oblong, erect, of a rich crimſon. *Cones* pendulous, ſolitary at the end of each branch, a ſpan long, nearly cylindrical, light brown, ſmooth, of numerous, imbricated, flattiſh, rigid, rhomboid ſcales, waved at the edge, and notched at the point. *Seeds* ſmall, with large elliptic-oblong wings.

21. P. *alba.* White Spruce Fir. Ait. H. Kew. ed. 1. v. 3. 371. Lamb. 39. t. 26. Willd. n. 34. Ait. n. 19. Purſh n. 7. (Abies alba; Mich. Arb. For. v. 1. 133. t. 12. A. piceæ foliis brevioribus, conis parvis biuncialibus laxis; Hort. Angl. 2. t. 1. f. 3.)—Leaves ſolitary, quadrangular, incurved. Cones nearly cylindrical; their ſcales obovate, wavy, entire. Common filament drooping, twice as long as the bracteas.—Native of high mountainous tracts in the colder parts of North America, flowering in May. Cultivated in England by biſhop Compton before 1700. *Miller.* It vies with the laſt in general form, but not in loftineſs, but the *leaves* are rather ſmaller, more ſwelling upwards, and more incurved, with a glaucous hue, and the *bark* of the trunk is whiter. The *flowers* are all ſmaller; the males diſtinguiſhed by the great length of their common filament, which is quite pendulous. The *cones* are not above two inches long, their ſcales obovate, not rhomboid. Mr. Lambert ſtrongly recommends the planting of this tree, on a large ſcale, on mountainous barren heaths in England and Ireland. Mr. Purſh however ſays its wood is not ſo good as that of the following, nor the tree ſo lofty; neither are its branches fit for making ſpruce beer.

22. P. *nigra.* Black Spruce Fir. Ait. Hort. Kew. ed. 1. v. 3. 370. Lamb. 41. t. 27. Willd. n. 31. Ait. n. 20. Purſh n. 5. (Abies nigra; Mich. Arb. For. v. 1. 123. t. 11. A. piceæ foliis brevioribus glaucis, conis biuncialibus laxis; Mill. Ic. t. 1.)—Leaves ſolitary, quadrangular, ſtraight. Cones ovate; their ſcales elliptical, notched at the end. Common filament erect, the length of the bracteas.—Native of the tracts of high mountains, from the more northern parts of Canada to Carolina, flowering in May. *Purſh.* It was introduced into England at the ſame time as the laſt, but is not much cultivated here. The wood is ſaid by Mr. Purſh to be better than the White Spruce, and the young branches are uſed for making the well-known ſpruce beer. The *leaves* and *flowers* are ſomewhat ſmaller than the laſt; the males erect, orange-coloured, their common filament no longer than the erect *bracteas,* the creſt of their *anthers* rounded, finely fringed. The *cones* are ovate, hardly above an inch long, crowded about the ſides of the laſt-year's ſhoots, which have protruded beyond them, and before they become dry, are of a rich deep purple.

23. P. *rubra.* Red Spruce Fir. Lamb. 43. t. 28. Willd. n. 33. Ait. n. 21. Purſh n. 6.—Leaves ſolitary, awl-ſhaped. Cones oblong, obtuſe; their ſcales rounded, ſomewhat cloven, the margin entire. Common filament ſhorter than the bracteas.—Found in Nova Scotia, and about Hudſon's Bay, flowering in May. Though Miller appears to have known this tree in cultivation, it is at preſent rarely ſeen, nor does it excite attention, except from the more curious obſervers. It is of more humble growth than the *nigra,* which it moſt reſembles, except that the *leaves* are awl-ſhaped; the unripe *cones* of a pale purpliſh-green, and when ripe rather oblong than ovate, their ſcales rounded, and not notched, but ſplit. The ſhoots are ſaid to make ſpruce beer.

24. P. *orientalis.* Oriental Fir. Linn. Sp. Pl. 1421. Willd. n. 35. Lamb. 45. t. 29. (Abies orientalis, folio brevi et tetragono, fructû minimo deorſùm inflexo; Tourn. Cor. 41. Voy. v. 2. 104. letter 17.)—Leaves ſolitary, quadrangular. Cones ovato-cylindrical, pendulous; their ſcales ſomewhat rhomboid.—Gathered by Tournefort, on lofty mountains above the convent of St. John, 25 miles ſouth-eaſt of Trebiſonde. The modern Greeks know this tree by the name of ἐλάτη, and it ſeems to be the only ſpecies of the ſpruce tribe that Tournefort found in the Levant. We know it merely from Mr. Lambert's plate, in which a copy of Aubriet's ſketch of an original ſpecimen, bearing two cones, is given; along with a coloured repreſentation of two other cones, from China, judged by Mr. Lambert to belong to the ſame ſpecies. The *leaves* of Tournefort's plant are very ſhort, being hardly half an inch long, ſomewhat incurved. *Cones* two inches long, ſtalked, quite pendulous, ovate and tapering, with rounded, entire, even ſcales; thoſe of the Chineſe plant are more ſeſſile, with more rhomboid wavy ſcales.

25. P. *Picea.* Silver Fir. Linn. Sp. Pl. 1420. Willd. n. 26. Ait. n. 22. Lamb. 46. t. 30. Woodv. Med. Bot. t. 209. (Abies mas; Ger. Em. 1363, 1364.)—Leaves ſolitary, flat, ſomewhat two-ranked. Cones cylindrical, erect, with long-pointed ſcales. Creſt of the anthers with two horns.—Native of the mountains of Siberia, Germany, and Switzerland; but not of Scotland, as Linnæus and Willdenow ſtate; nor of Sweden, as the latter erroneouſly borrows from the former, printing *Sueciæ* for *Sueviæ.* A tall and handſome tree, cultivated for ornament in England, and flowering in May. Its *bark* is ſmooth and whitiſh. *Branches* horizontal. *Leaves* copious, linear, either acute or emarginate, entire, ſpreading, more or leſs perfectly, in two ranks, and ſometimes curved toward one ſide; their upper ſurface of a dark, ſhining, rather glaucous, green; the under glaucous-white. Male *flowers* numerous, axillary, ſolitary, about as long as the leaves, yellow; their common filament the length of the toothed *bracteas; anthers* remarkable for their rounded two-lobed creſt, crowned with a pair of divaricated horns. Female *catkins* lateral, erect, cylindrical, green, one lip of each ſcale, much the narroweſt, diſtinguiſhed by a long, projecting, awl-ſhaped point, very conſpicuous in the full-grown *cones,* which are alſo erect, three or four inches long, cylindrical, of a reddiſh-green, till they turn brown in drying. Gmelin aſſerts that foreſts of this tree are conſidered, by the wandering Tartars, as a ſure indication of good ſprings, as it delights in moiſt rich ſituations; an obſtacle to its being planted much for profit in England.

26. P. *Balſamea.* Balm of Gilead Fir. Linn. Sp. Pl. 1421. Willd. n. 27. Ait. n. 319. Purſh n. 1. Lamb. 48. t. 31. (Abies balſamifera; Mich. Boreal-Amer. v. 2. 207. Mich. Arb. For. v. 1. 145. t. 14.)—Leaves ſolitary, flat, imperfectly two-ranked. Cones cylindrical, erect, with ſhort-pointed ſcales. Creſt of the anthers pointleſs.—Native of Canada, Nova Scotia, New England, and the Allegany mountains, in high cold ſituations, flowering in May. *Purſh.* It has long been cultivated for curioſity in England, but in general, though it grows to a conſiderable ſize and height, ſcarcely ſurvives above 20 years, which ſeems to be the natural period of its exiſtence. In this reſpect our obſervations agree with thoſe of Miller and Mr. Lambert; though the latter has been told of ſome older trees of this ſpecies at Wooburn and Warwick-caſtle. Its fragrant ex-

udation is the well-known Canada balfam, which fome quacks celebrate as Balm of Gilead, to their own profit, if not to that of their patients. Combined with fome kind of fpirits, it makes a not unpleafant dram. This tree and its foliage are not much unlike the laft, but the above characters clearly diftinguifh it. The full-grown *cones* are of a beautiful violet hue, and exude plenty of candied turpentine or balfam, as does the trunk when wounded.

27. P. *Fraferi.* Double-balfam Fir. Purfh n. 2.—Leaves folitary, flat, emarginate. Cones ovate-oblong, erect, their fcales elongated, reflexed, oblong-wedgefhaped, emarginate, fhort-pointed, toothed. Found on the high mountains of Carolina, by the late Mr. Frafer, by whom it has been introduced into England. Mr. Purfh, who met with the fame fpecies on the Broad-mountains, Pennfylvania, defcribes it as a fmaller tree than the laft, with fhorter more erect *leaves*, and *cones* not one-fourth fo large.

28. P. *taxifolia.* Nootka Fir. Lamb. 51. t. 33. Willd. n. 29. Purfh n. 3.—Leaves folitary, flat, entire. Cones oblong. Anthers of two inflated lobes; their creft minute, reflexed; common filament fhorter than the concave fringed bracteas.—Gathered by Mr. Menzies at Nootka found; "by Mr. Lewis on the banks of the Columbia." *Purfh.* A tall elegant tree, bearing fome refemblance to the following, but the *leaves* are more than twice as long, and entire. The *anthers* too, as far as they could be made out from a dried fpecimen, appear very different; and the *cones* are faid by Mr. Menzies to be longer, as well as differently fhaped.

29. P. *canadenfis.* Hemlock Spruce Fir. Linn. Sp. Pl. 1421. Willd. n. 30. Ait. n. 24. Purfh n. 4. Lamb. 50. t. 32. (Abies canadenfis; Mich. Boreal-Amer. v. 2. 206. Mich. Arb. For. v. 1. 137. t. 13.)—Leaves folitary, flat, two-ranked, finely toothed. Cones terminal, ovate, fcarcely longer than the leaves. Anthers capitate, beaked; common filament twice as long as the bracteas.—"Native of the moft northern regions of Canada, and on the higheft mountains, as far as South Carolina, flowering in May. A very elegant tree, growing in fome fituations to an enormous fize; its bark is a fine fubftitute for oak-bark in tanning." *Purfh.* Peter Collinfon records his having introduced this tree, in 1736, to the Englifh collections, and a fine fpecimen of it is, or was, in his garden at Mill Hill. The afpect of the Hemlock Spruce is rather gloomy, partaking more of the yew than of the fir. The male *flowers* are fmall, confifting of very few *anthers*, in a round head on a long common filament. The *cones* are fcarcely an inch long, fmooth, pale, of but few fcales, and hang folitary at the ends of the fmall ultimate branches. The *leaves* are glaucous underneath in this, as well as in four fpecies immediately preceding.

30. P. *lanceolata.* Lance-leaved Chinefe Pine-tree. Lamb. 52. t. 34. Willd. n. 28. Ait. n. 25.—Leaves folitary, lanceolate, flat, fpreading, with taper pungent points. Cones globofe, with pointed fcales.—Gathered by the late fir G. L. Staunton, bart. in the province of Chekiang, China, from whofe fpecimen Mr. Lambert at firft publifhed an uncoloured figure. A coloured drawing, with a diffection of the *cone*, difplaying the *feeds*, each of which is reprefented as encompaffed with an oval wing, was fubfequently fent from Canton by an artift in the employment of the Eaft India Company; by all which Mr. Lambert has profited. Living plants have alfo been brought to Kew in 1804, and are now cultivated in the green-houfes of that and fome other choice collections, but have not yet bloffomed. The afpect of this *tree* or *fhrub*, for we know nothing of its natural ftature, is fo unlike all other pines or firs, that its unripe *cones* were actually fuppofed to be excrefcences, or galls, owing to the attacks of infects. The copious, deflexed, rigid, pungent *leaves*, near an inch and a half long, of a fine green, fpread in every direction; they are entire, but rough-edged, and furnifhed with three ribs. *Cones* about as big as wall-nuts, feffile, rather drooping, almoft globular, of many ovate pointed fcales.

Sect. 3. *Leaves numeroufly tufted from each fheath.* LARIX of Tournefort. Four fpecies.

31. P. *Larix.* Common, or White, Larch-tree. Linn. Sp. Pl. 1420. Willd. n. 24. Ait. n. 26. Lamb. 53. t. 35. Woodv. Med. Bot. t. 210. (Larix; Matth. Valgr. v. 1. 95. Ger. Em. 1365. Camer. Epit. 45, 46.)—Leaves tufted, deciduous. Cones ovate-oblong; the margins of their fcales reflexed, jagged. Scales of the female catkin fiddle-fhaped, prominent in the full-grown cone. Native of the alps of Switzerland, Italy, Germany, Siberia, &c., long cultivated very extenfively, and with great advantage in this country, flowering in March and April, before the leaves fully expand, in which ftate it makes an elegant appearance. Mr. Lambert's plates of this and the following are no lefs beautiful pictures, than exquifitely faithful botanical drawings. The fame may indeed be faid of his whole work. The larch is a tree of ftraight and lofty growth, as well as large bulk, with wide-fpreading *branches*, whofe extremities droop in the moft graceful manner. In a wild ftate its form is, of courfe, lefs regular, but more picturefque. The *buds* are alternate, perennial, cup-fhaped, fcaly, each producing annually a pencil-like tuft of very numerous, fpreading, linear, bluntifh, entire, fmooth, tender, bright-green, deciduous *leaves*, about an inch long, with no other *ftipulas* than the fcales of the bud. How many years each bud endures, we have not determined, but certainly above four or five. From fimilar buds fpring feparately, on the fame branch, the male and female *flowers*, the latter only accompanied by a few leaves; but it feems to us, that the male buds become entirely leaf-buds, in the fucceeding feafons. *Bracteas* to each flower numerous, recurved, obtufe, with fine fringe-like teeth, chaffy, red-brown, deciduous. Male *flowers* yellow, drooping, about half an inch long. Common *filament* much fhorter than the *bracteas*; *anthers* crowded, deflexed, inflated, and two-lobed in front, with a fhort recurved point. Female *catkins* erect, larger than the male *flowers*, beautifully variegated with green and pink; one lip of each fcale orbicular; the other much larger, fiddle-fhaped, reflexed, with a prominent, awl-fhaped, green point. This lip becomes erect, and fomewhat enlarged, projecting always beyond the orbicular one, which dilates greatly, hardens, and becomes the feed-bearing fcale of the *cone*. The *cones* are erect, rather above an inch long, ovate; purple when young; reddifh-brown when ripe, light, not ponderous, their fcales fpreading, orbicular, flightly reflexed, and jagged, or cracked, at the margin. Wing of each *feed* half-ovate.

32. P. *pendula.* Black Larch-tree. Tamarack or Hackmatack of the Americans. Ait. Hort. Kew. ed. 1. v. 3. 369. Lamb. 56. t. 36. Willd. n. 22. Ait. n. 27. Purfh n. 18.—Leaves tufted, deciduous. Cones oblong; the margins of their fcales inflexed. Scales of the female catkin fiddle-fhaped, concealed in the full-grown cone.—Found in low cedar fwamps, from Canada to New Jerfey, flowering in April and May. *Purfh.* It was firft raifed in England by the celebrated P. Collinfon, whofe original tree, one of the treafures of the Mill Hill garden, was cut down about the year 1800, to make a rail, by its fapient poffeffor. The abundance of feeds, which it annually produced, might have

have been a far more lafting fource of profit, as few exotic trees are more worthy of general cultivation. The wood is at leaft equal to the European larch, and the bark excellent for tanning. The habit and *foliage* refemble the preceding, but the female *catkins* are reprefented by Mr. Lambert of a more crimfon hue. The fiddle-fhaped pointed lip of each of their fcales is four or five times as big as the orbicular one, but never increafes after the flowering period; fo that it becomes entirely concealed, in the full-grown *cones*, by the enlarged orbicular lips, that conftitute the proper fcales of the *cones*, and twice exceed it in length. This circumftance did not efcape the excellent Solander, who firft defcribed the prefent fpecies, from Mr. Collinfon's garden. The *fructification* for the moft part agrees with *P. Larix*, infomuch that it is difficult to find fpecific diftinctions. The *cones* however are fmaller, more cylindrical, with rather fewer *fcales*, whofe edges are flightly inflexed, and this, added to the want of the pointed prominences feen in the foregoing, give the full-grown dark purple *cones* a peculiar neatnefs and fmoothnefs of appearance.

33. *P. microcarpa.* Red Larch-tree. Lamb. 58. t. 37. Willd. n. 23. Ait. n. 28. Purfh n. 19. (P. pendula; Willd. Baumz. 215. Larix americana; Mich. Boreal. Amer. v. 2. 203. Mich. Arb. For. v. 3. 37. t. 4.)—Leaves tufted, deciduous. Cones roundifh, of few fcales; their margins inflexed. Scales of the female catkin oval, concealed in the full-grown cone.—Found about Hudfon's Bay, and on high mountains of New York and Pennfylvania, flowering in May. *Purfh.* Michaux, it feems, has confounded this with the laft, as did Willdenow in his valuable German work on hardy trees and fhrubs, publifhed at Berlin in 1796. This is fimilar to *P. pendula* in general appearance, but the *leaves* are rather fmaller, and the *cones* confiderably fo, being rounder and compofed of much fewer fcales. The male *flowers* are more fhort and tufted, their *anthers* fcarcely projecting beyond the *bracteas*. The pointed lip of each fcale of the female *catkin* affords the moft clear diftinction, being elliptical, not fiddle-fhaped. The copious crimfon *cones*, fully grown but not ripe, make a beautiful appearance in fummer. Such was the ftate of the tree of this fpecies, which Mr. Lambert, in company with the writer of the prefent article, found unprotected in the middle of a pafture at Whitton, near Hounflow, where it had been planted by John duke of Argyle. It had however efcaped injury, and was immediately fecured from further danger. Both thefe American Larches are now in cultivation amongft the nurferymen, and deferve the attention of planters.

34. P. *Cedrus.* Cedar of Lebanon. Linn. Sp. Pl. 1420. Willd. n. 21. Ait. n. 29. Lamb. 59. t. 37, *bis.* (Larix orientalis, fructu rotundiore obtufo; Tourn. Inft. 586. Duham. Arb. v. 1. 332. t. 132. Cedrus; Trew Ehret. 1, 28. t. 1, 60, 61. Camer. Epit. 57. C. Libani; Ger. Em. 1352. Matth. Valgr. v. 1. 114.)—Leaves tufted, perennial. Cones ovate, abrupt; their fcales clofe-preffed. Creft of the anthers ovate, flat, erect.—Native of mountains in the Levant, efpecially of the famous Lebanon, from whence feeds were obtained, and plants raifed in the Englifh gardens, towards the latter part of the feventeenth century. Two of the oldeft of thefe venerable guefts remain at Chelfea, and others of fomewhat younger growth at Chifwick, Whitton, Pain's hill, &c. A very large one at Hillingdon was blown down above twenty years ago. The widefpreading fan-like branches, and perennial *leaves* of this fpecies, differ widely from the three foregoing. Its male *flowers* are extremely different, both in their long cylindrical form, and the erect ovate red creft of their *anthers*, more agreeing with fome of our firft-defcribed kinds. The female *catkins* are ovate, dull-purple; both lips of their fcales nearly orbicular, and clofe-preffed. The larger has at its bafe, on each fide, attached to the rudiments of the *feeds*, a pair of combined awl-fhaped proceffes, that might be taken for *ftyles* or *ftigmas*, could any analogous parts be found in other fpecies of *Pinus*. Thefe are, for the firft time we believe, reprefented in a fine plate by Mr. Sowerby, added to Mr. Lambert's work after its original publication. Which of thefe lips changes into each hardened dilated abrupt fcale, of the large ponderous *cones*, we have not had an opportunity of obferving. Something fimilar to the above ftyle-like proceffes of the Cedar, is fhewn in Mr. Lambert's plate of *P. pendula*, at the diffected *fcales* of the full-ripe *cones*; where however it has all the appearance either of pubefcence, or of lacerated fibres.

Sect. 4. *Leaves oppofite.* Agathis. Salis. Tr. of Linn. Soc. v. 8. 311. t. 15. One fpecies.

35. P. *Dammara.* Amboina Pitch Pine-tree. Lamb. 61. t. 38. Willd. n. 25. Ait. n. 30. (Dammara alba; Rumph. Amb. v. 2. 174. t. 57.)—Leaves oppofite, elliptic-lanceolate, ftriated.—Native of Amboina, where a fine inflammable refin exudes from the trunk when wounded, and is collected for fome purpofe, not clearly explained by authors. A kind of pitch is alfo faid to be made from this tree, much ufed in the Eaft Indies. Of its botanical hiftory we know little. The elliptic-lanceolate, thick, rigid, oppofite *leaves*, near three inches long and one broad, are widely different from every known *Pinus*, and there is every reafon to fuppofe the *Dammara* conftitutes a diftinct and dioecious genus; though all that has as yet been explained relative to its fructification is little more than conjecture. The ripe *cones* are globular, clofe, hard, and woody, as big as a fmall orange, with tumid, teffellated, unarmed *fcales*. Other cones bear fomething like *anthers* at the bafe of each fcale. Living plants of *P. Dammara* were procured by fir J. Banks for Kew garden in 1804, and are kept in the ftove.

Pinus, in *Gardening*, contains plants of the evergreen and deciduous tree kinds, of which the fpecies cultivated are; the wild pine-tree (P. fylveftris); the pinafter, or clufter pine-tree (P. pinafter); the Jerfey pine-treo (P. inops); the American pitch pine-tree (P. refinofa); the Aleppo pine-tree (P. halepenfis); the ftone pine-tree (P. pinea); the torch pine-tree, or three-leaved Virginia pine (P. tæda); the fwamp pine-tree (P. paluftris); the Siberian ftone pine-tree (P. cembra); the Weft Indian pine-tree (P. occidentalis); the Weymouth pine-tree (P. ftrobus); the cedar of Lebanon (P. cedrus); the black larch-tree (P. pendula); the common white larch-tree (P. larix); the filver fir-tree (P. picea); the balm of Gilead fir-tree (P. balfamea); the hemlock fpruce fir-tree (P. canadenfis); the black fpruce fir-tree (P. nigra); the Norway fpruce fir-tree (P. abies); the white fpruce fir-tree (P. alba); and the oriental fir-tree (P. orientalis).

The trunks of the firft fort of thefe afford mafts to our navy, and from them and the branches tar and pitch are obtained, as alfo by incifion, barras, Burgundy pitch, and turpentine.

There are feveral varieties; as the Tartarian, which has a great refemblance to it, but the leaves are broader, fhorter, and their points are more obtufe; they emit a ftrong balfamic odour when bruifed; the cones are very fmall, as are alfo the feeds, fome of which are black, and others white.

The mountain, or mughoe, which has very narrow green leaves, grows fometimes by pairs, fometimes by threes from the fame fheath, generally ftanding erect; the cones are of a middling fize, and pyramidal; the fcales flat, having each a ſmall obtuſe riſing, but very compact till they are opened by the warmth of the ſun the ſecond ſpring; the ſeeds of this are much leſs than thoſe of the ſecond ſort, but larger than thoſe of the firſt. It is a native of the Swiſs mountains, where it is often called torch pine, growing to a great height.

The ſea pine, which has ſmooth leaves; the cones are very long and ſlender; and the ſeeds are about the ſame ſize with thoſe of the ſecond ſpecies. It grows in the maritime parts of Italy, &c.

Other varieties are likewiſe mentioned by writers.

Of the ſeventh ſort there are different varieties; as the three-leaved Virginia, which has the leaves long, generally three in each ſheath; the cones in cluſters round the branches, as long as thoſe of the ſecond ſort, but with rigid ſcales; the ſeeds alſo nearly as large as thoſe of it. It grows naturally in Virginia, and other parts of North America, where it riſes to a great height.

The other varieties differ but little from this.

The twelfth ſort, or cedar, is now ſo far naturalized to our country as to produce ripe ſeeds; we may, therefore, have ſupplies without depending on the cones from the Levant: but it is found that they are more apt to produce and ripen their cones in hard winters than in mild ones; which is a plain indication that they will ſucceed even in the coldeſt ſeaſons of the northern parts of the iſland, where, as well as in the other parts, they might be propagated to great advantage.

There are different varieties of the fourteenth ſort; the American, the Siberian, and the Chineſe, require a colder climate than England, for the trees are apt to die in the ſummer here, eſpecially if they are planted on a dry ſoil; the cones of thoſe which have been brought to England ſeem to be in general larger than thoſe of the common ſort; but there is ſo little difference between the trees in their characteriſtic marks, that they cannot be diſtinguiſhed as different ſpecies, though in the growth of the trees there is a remarkable difference. In the laſt, the cones are much larger than thoſe of the common ſort, and end in acute points; the ſcales prominent, like thoſe of the firſt ſpecies, and have little reſemblance to thoſe of the larch. They are of a ſhrubby, ſpreading growth, but ſo hardy as to thrive in the open air without any protection. But in the firſt, of which the branches are more ſlender, with a bark more inclining to yellow, and the ſcars more ſlender and cluſtered; the leaves are more tender, narrow, more glaucous, and the outer ones in each bundle ſhorter; cones only one-third of the ſize, blunt, with ſcales ſcarcely exceeding twelve in number, thinner, more ſhining, retuſe, emarginate; the wings of the ſeeds are ſtraight, more oblong, narrower, and, together with the ſeed itſelf, of a more diluted grey colour. And in the ſecond, the bark of the branches is of an aſh-coloured grey; the leaves a little wider, bright green, all nearly equal, commonly more than forty in a bundle; the cones an inch long, with above thirty woody, ſtriated, rounded, entire ſcales; the ſeeds browniſh-grey, with ſubtriangular wings, ſomewhat bent in. In both the cones are bent upwards, on very ſhort peduncles.

It is obſerved by the editor of Miller's Dictionary, that "no tree is more valuable; or better deſerves our attention in planting than the larch." It is a native of the ſouth of Europe, and Siberia.

The timber is not only uſed in houſes but in naval architecture alſo. "It ſeems to excel," he ſays, "for beams, doors, windows, and maſts of ſhips; it reſiſts the worm; being driven into the ground it is almoſt petrified, and will ſupport an incredible weight; it bears poliſhing excellently well, and the turners abroad much deſire it. It makes everlaſting ſpouts, pent-houſes, and feather-edge, which need neither pitch nor painting to preſerve them; excellent pails, poſts, rails, props for vines, &c.; to theſe we may add the palettes on which painters ſeparate and blend their colours."

It has been obſerved in Ireland, that no tree grows ſo ſpeedily to ſo large a ſize as the fifteenth ſort, or the ſilver fir. Some at forty years growth, in a wet clay on a rock, meaſuring twelve feet in circumference at the ground, and ſeven feet and a half at five feet high; one tree containing ſeventy-ſix feet of ſolid timber. The earl of Fife alſo remarks that no trees make a greater progreſs than this and the larch. It is found to be excellent for boat-building.

The ſeventeenth ſort has very much the habit of the ſilver fir, but the leaves are wider and blunter, diſpoſed on each ſide along the branches like the teeth of a comb, but in a double row, the upper one ſhorter than the under; underneath marked with a double glaucous line, and each has eight rows of white dots, and are often cloven at top.

The appellations of white and black in the ſeventeenth and eighteenth ſorts are given from the colour of the bark, as there is little difference in the colour of the wood, and the leaves of the black are whiter on their under ſide than thoſe of the white. They are both natives of North America; the white upon the mountains; the black upon the low grounds, generally in bogs or ſwamps. The firſt is by much the largeſt tree. This (the black) ſort is eaſily known by its narrow leaves, placed on every ſide of the branches, and its long pendulous cones, which do not fall to pieces on the tree, but drop off entire the following ſummer; the ſcales open and emit the ſeeds on the firſt warmth of the ſpring.

There is a variety of this tree cultivated under the title of the long-coned Corniſh fir, in which the leaves are longer, broader, of a lighter colour, and fuller on the branches; the cones alſo longer.

In the nineteenth ſort there are two principal varieties; the white and the red, both of which afford the white deals. And *Burgundy pitch* is prepared from the reſin procured from this tree by boiling and ſtraining it through a cloth.

There is no tree that yields greater profit than the ſpruce fir in cold land; no tree is more beautiful ſtanding ſingle on turf in large plantations, or more uſeful for ſhelter in cold ſoils and ſituations.

Method of Culture.—In all the ſorts and varieties the increaſe is effected by means of ſeeds, which may be obtained from the well ripened cones by expoſing them to the heat of a gentle fire, or that of the ſun, in which way the cells open and the ſeeds may be readily taken out. When the cones are not made uſe of in this way, they will remain ſeveral years without the ſeeds being injured, eſpecially where they are cloſe.

They ſhould be ſown in the early ſpring months, as March or the following month, on beds of fine earth, in a north-eaſt aſpect, or in large pots or boxes for the purpoſe of being occaſionally removed into different ſituations as may be found neceſſary. They ſhould be covered with nets to prevent the birds from pecking off the tops of the young plants, while the huſks of the ſeeds are upon them; and be likewiſe ſcreened from the heat of the ſun at firſt.

All the ſorts, except the ſtone pine and a few others, the ſcales of the cones of which are very hard, ſoon come up; but theſe frequently remain more than a year; the ground ſhould therefore not be diſturbed, being only kept clean from weeds in ſuch caſes.

Soaking the feeds in thefe cafes may be ufeful, as well as fowing them in fhaded fituations.

The young plants in all the forts fhould be kept quite clean, and occafionally refrefhed with water when the feafon is dry, in a very gentle manner, fo as not to difturb the plants.

When they come up too clofe, the plants fhould be thinned out in the fummer, the thinnings being planted out immediately in a feparate bed, in a fhady place, being gently watered as there may be occafion. They fhould be fet out in rows at the diftance of four or five inches, and three or four in the rows. The tender kinds fhould be fheltered during the winter by frames or mats from the frofts, but with the others it is unneceffary.

When the plants have remained in thefe beds a year or more according to circumftances, they fhould be removed into other rows in the nurfery at the diftance of two feet, and one or more in the rows. In this fituation they fhould remain till the periods of their being finally planted out.

The beft feafon for the removal of the plants in all cafes is towards the latter end of March, or the beginning of the following month.

Where it can be done, it is the beft way not to let them remain too long in thefe nurfery fituations, as the plants are always found to fucceed beft when planted out before they have acquired too large a growth.

When large plantations are to be made, it is advifed by fome to raife the plants on a portion of the fame ground, or as nearly fimilar to it as poffible.

It is advantageous when they are to remain, to have a large fize to tranfplant them every two years, as by that means they form better roots, and fuch as fpread out more laterally, and of courfe the plants may be afterwards removed with greater fafety.

In removing the plants, at all times great care fhould be taken to preferve the roots as much as poffible, as well as all the branches, without cutting them.

When they have been finally removed, they require little more trouble, it being only neceffary to keep them perfectly free from weeds, and fupporting the larger forts of plants with proper ftakes; all the forts fhould be fuffered to take their own natural growth; being careful to preferve their tops perfectly entire, to fhoot up as faft as poffible, and to branch out in their own way, as no pruning is wanted, unlefs in the lowermoft branches in particular trees which are thought too low and ftraggling, when thefe may be occafionally trimmed, cutting them clofe to the ftem; but pruning fhould be very fparingly practifed to thefe refinous trees, as lopping the branches contributes to retard their growth as well as impair their beauty. In large foreft plantations, where the trees are arrived to a large growth, it is, however, cuftomary to lop their lower branches gradually for faggots, according as they begin to decay; for where thefe trees ftand clofe, the upper branches generally kill thofe below, fo that the lower tiers decay gradually and fucceffively; in which cafe thefe decaying lower branches may be lopped by degrees in winter.

After the plantations defigned for timber-trees have had eight, ten, or twelve years' growth, it may be proper to begin to thin them; thofe thinned out may ferve for many fmaller purpofes, being careful in thinning to leave a fufficiency of the fineft plants ftanding at proper diftances to grow up for timber.

Thefe trees are all highly ornamental evergreens for the pleafure-grounds.

In regard to the diftribution or arrangement of the trees in the plantations, and mode of planting, thofe defigned for the fhrubbery and for ornamental plantations may be difpofed both in affemblage with other trees, and to form clumps, and continued plantations. Thofe intended as foreft trees fhould generally be difpofed alone in confiderable plantations. The method of planting them is the fame as in other hardy trees; but where large plantations in out-grounds are intended either for pleafure or profit, there will not be any great neceffity for a previous preparation of the foil, with refpect to digging or ploughing, only juft to dig a hole for each tree; the fame rule may alfo be obferved in planting clumps of them in lawns, parks, and other grafs-grounds, the mould being made fine in the bottoms of them. Thofe defigned principally for ornament fhould be difpofed at fuch diftances as that their branches may extend freely every way; as the beautiful difplay of the head is a great merit in thefe trees in fuch plantations; but thofe intended for timber plantations may be put only four or five feet diftant, in order that they may draw one another up ftraight and tall more expeditioufly, and to admit of a gradual thinning after a few years' growth, for poles, &c.

The proper methods of raifing and planting out all the different forts, in the view of affording timber or fhelter in large plantations, may be feen in the new edition of Miller's Dictionary.

PINUS, in *Ornithology*, a fpecies of *Certhia*; which fee.

PIN-YANG, in *Geography*, a city of China of the firft rank, in Chan-fi; 337 miles S.W. of Peking. N. lat. 36° 6′. E. long. 111° 0′.

PIO, ALBERTO, in *Biography*, prince Carpi, fon of Leonello, lord of Carpi, by a fifter of the celebrated Giovanni Pico of Mirandula, was born about the year 1475, and firft ftudied in the univerfity of Ferrara under Pomponazzo. He purfued his ftudies with great ardour at Carpi, whither he had invited feveral learned men, among whom he diftinguifhed Aldo Manuzio as his particular inftructor. After his father's death, he, with his brother Leonello, had a common dominion in the territories of Carpi, with Giberto and other fons of Marco, another branch of the fame family. This divided authority produced diffenfions, which, from 1494 to 1500, occafioned a bloody civil war. After a time, Alberto connected himfelf with the French party, and in 1510 he vifited the court of Lewis XII., and was difpatched by him in a miffion to pope Julius II., and fome circumftances now occurred which led him to believe that it was his intereft to quit the French party, and to join that of the Imperial, the latter being the ftronger in Italy, which he did not hefitate to fay was the motive by which he was governed in his political alliances. He refided a long time at Rome as the emperor's ambaffador at the papal court, and was fingularly efteemed by Leo X., who conferred upon him feveral caftles in Romagna. In the fubfequent wars his principality was frequently taken by different parties, and Alberto was poffeffed and difpoffeffed of the fovereignty. He again adopted the French intereft, which occafioned the final lofs of Carpi, that was transferred by Charles V. to Alfonfo, duke of Ferrara. He was at Rome during its fack in that year; and took refuge with Clement VII. in the caftle of St. Angelo. Being afterwards delegated by the pontiff to Francis king of France, he was very handfomely received by that monarch, and died at his court in 1531, in the 56th year of his age. Notwithftanding the viciffitudes of his life, and his various political occupations, Alberto did not ceafe the cultivation of letters; he was a zealous adherent to the fee of Rome, and gave all the oppofition in his power to the doctrines of the reformers. At this time Erafmus made a confiderable figure in the world, and Alberto fpoke pretty freely of the tendency of his various

rious publications, and what he faid was reported with much aggravation to that celebrated man. In confequence he wrote, in October 1525, a letter to Alberto, acquainting him in a friendly manner with what he had heard, and fubjoining a fhort defence of himfelf. To this Alberto replied in a long epiftle, which, with Erafmus's letter, was afterwards publifhed at Paris. This led to farther difcuffion on both fides, and in one of his letters, Alberto launched out into an examination of all the works and opinions of Erafmus, and of thofe of Luther, and the other innovators of the time. He died, while the work was printing, at Paris, but it appeared in the fame year under the title of "Alberti Pii, &c. tres et viginti libri in locos lucubrationum variorum D. Erafmi Rotter." This work is highly commended by Tirabofchi, who fays "it has none of the fcholaftic barbarifm, but is written with erudition, force, and not without elegance." It fhould be obferved, that he was fuppofed to have been affifted by Sepulveda, and other learned men whom he kept in his houfe. His works have been collected and publifhed in folio at Paris, and alfo at Venice.

PIOBBICO, in *Geography*, a town of the duchy of Urbino; 11 miles S. of Urbino.

PIOBRACH, a Gaelic term, denoting an air played upon the bag-pipe; and now more ftrictly applied to the ancient Highland martial mufic. This air is faid to be peculiarly expreffive. Piobrachs are either fimple or compound; fome of them confift of a march, &c. and are beautifully varied, and highly characteriftic.

PIOMBA, in *Geography*, a river of Naples, which runs into the Adriatic, N. lat. 42° 56'. E. long. 13° 9'.

PIOMBINO, a principality in the central part of Italy, confifting of a fmall portion of the Italian fhore, and the oppofite ifle of Elba, fubject, in the 13th century, to the Pifans, and after feveral revolutions transferred to the family of Appiano, as a detached principality, in 1399. In 1501 it was feized by Cæfar Borgia, but after the death of pope Alexander VI. returned to the houfe of Appiano. In the 16th century the ifle of Elba was repeatedly ravaged by the Turks. The principality recently paffed to the houfe of Buoncompagni, that is, the dukes of Sora, a Neapolitan family, which owes its fortune to the pontiff Gregory XII., and in 1801 annexed to the new kingdom of Etruria. It is fituated on a peninfula, in a bay of the Mediterranean, called "the gulf of Piombino." Piombino is a fmall neglected town; 33 miles S.W. of Sienna. N. lat. 42° 57'. E. long. 10° 34'.

PIOMBO, Sebastian del, in *Biography*, called alfo *Venetiano*, from Venice, the place of his birth, which occurred in 1485. He was renowned in early life as a mufician, and particularly for his fkill in playing upon the lute. While he was yet in his youth, he abandoned that fcience, and was taught the rudiments of the art of painting by Giovanni Bellini; but as Giorgione da Caftel Franco had juft then exhibited his improved mode of colouring and effect, Sebaftian placed himfelf under his tuition; and in the end acquired a well merited and great renown, both in painting portraits and hiftorical fubjects.

His firft effays were in the former clafs, and they were greatly admired for the ftrength of refemblance, and the fweetnefs and fulnefs of ftyle with which they were executed; and were frequently miftaken for the work of Giorgione. His portrait of Giulio Gonzaga, the favourite of cardinal Hippolito di Medici, is by many writers fpoken of with extreme delight, and called a divine performance, full of life and character. He finifhed his works with great care; folding his draperies with great felicity, and giving great truth and exactnefs of action to the heads and hands.

By the perfuafion of Agoftino Ghizi, a rich merchant of Sienna, he was induced to go to Rome; where the novelty of his ftyle, and his fkill in execution, foon drew him into public notice. He there became an hiftorical painter, and wrought equally well in frefco and in oil. In the conteft of opinion which took place at that time concerning the fuperiority in merit of Raphael, or M. Angelo, Sebaftian gave the preference to the latter, and gained his efteem and fupport. In confequence he was favoured by him on all occafions; and fo highly eftimated, that he ftimulated him to the rafh attempt of rivalling Raphael; particularly by painting a picture in competition with that great man's laft great work, the Transfiguration; which had juft been placed, with great éclat, in the church of St. Pietro à Montorio. The fubject Sebaftian chofe, was the refurrection of Lazarus; for which Michael Angelo is fuppofed to have furnifhed the defign, or at leaft to have confidered and retouched it. The picture is of the fame fize as Raphael's, and, when completed, was placed in the fame Confiftory, and was very highly applauded. The cardinal di Medici fent it to his bifhopric of Narbonne, and it became the property of the duke of Orleans. It is now in England, and in poffeffion of J. Angerftein, efq. who gave 2000 guineas for it to the proprietors of the Orleans collection. Although it is a work of profound fkill, and highly preferves the reputation of its author, yet, in our opinion, it is not to be compared with the great work it was intended to rival, either in defign, in expreffion, or effect; whatever may be faid of its execution.

Sebaftian continued to exercife his talents, particularly in portraiture, with great induftry and fuccefs, till he obtained the office of Frate del Piombo; when he ceafed to paint for profit; and was henceforward known by the name of Sebaftian del Piombo. He lived in great efteem with pope Clement VII., whofe portrait he painted with great power and fidelity; as well as that of the ingenious fatirift Aretine; and thofe of many perfons of rank and renown. He obtained great praife for having difcovered a mode of preventing oil colours, employed on plaifter, from becoming dark; which he did, by applying, in the firft inftance, a mixture of maftic and Grecian pitch. Having paffed through a life of great honour and emolument to the age of 62, he then fhared in the common fate of human nature, and died in the year 1547.

PIONEER, in *War*, a labourer employed in an army, to fmooth the roads, pafs the artillery along, and to dig lines and trenches, mines, and other works.

Menage derives the word from the Latin *peditones*, a diminutive of *pedites*. Bochart deduces it from the Pæones, a people of Afia, whofe principal employment was to dig the earth in mines, &c.

Moft of the foreign regiments of artillery have half a company of pioneers well inftructed in their bufinefs. Our regiments of infantry and cavalry have three or four pioneers each, provided with aprons, hatchets, faws, fpades, and pick-axes. They have alfo a cap with a leathern crown, and a black bear-fkin front, on which is the king's creft in white, on a red ground, and the number of the regiment on the back part of the cap.

PIONSAT, in *Geography*, a town of France, in the department of the Puy-de-Dome, and chief place of a canton, in the diftrict of Riom; 22 miles N.W. of Riom. The place contains 1680, and the canton 8026 inhabitants, on a territory of 170 kiliometres, in 10 communes.

PIONTAK, a town of the duchy of Warfaw; 20 miles E.S.E. of Lenciez.

PIONY, in *Botany*. See Pæonia.

PIORAS

PIORAS *Fort and Village, Old*, in *Geography*, are fituated in the north-weft territory of America, on the weft fhore of Illinois river, and at the fouth end of Illinois lake; 210 miles from Miffifippi river. The ftockaded fort commands a fine profpect of the country to the eaftward of the lake, to the point where the river enters it at the north end; to the weftward are large meadows, and a level country full of fwamps, and containing abundance of cherry, plum, and other fruit-trees. The lake, which is merely a dilatation of the river, $19\frac{1}{2}$ miles long, and 3 broad, contains plenty of fifh, and particularly fturgeon and picannao. The Indians, at the treaty of Grenville, in 1795, ceded to the United States a tract of 12 miles fquare at this fort. N. lat. 40° 53'. W. long. 91° 12' 30".

PIORIAS *Wintering Ground*, a tract of land in the Indiana territory, on the fouth-eaft fide of Illinois river, about 40 miles above and north-eaft of the Great Cave, on the Miffifippi, oppofite to the mouth of the Miffouri, and 27 below the ifland of St. Pierre. On a meadow, eaft of the river, many miles long, and five or fix broad, are many fmall lakes, communicating with each other, and one of them with the Illinois river.

Piorias, an Indian nation of the Indiana territory, who, with the Mitchigamias, could furnifh, about 40 years ago, 300 warriors. They occupy the parts near the fettlements in the Illinois country. A tribe of this name inhabit a village on the Miffifippi, a mile above fort Chartres. This tribe could furnifh, about the fame period, 170 warriors of the Piorias and Mitchigamias.

PIOSSASU, a town of France, in the department of the Po; 10 miles W.S.W. of Turin.

PIOZZI, Signor, in *Biography*. Though we have adhered as clofely as poffible to the rule of confining our remarks on mufical compofers and performers to the dead, of whom an opinion may be given without fear of offence, if unfavourable, or of exciting envy by eulogies; yet fignor Piozzi, though ftill living (1814), may be excepted from this rule, as he has long retired from all profeffional concerns, and as we had nothing but good to fay of his talents.

He arrived in England about the year 1777. His voice was not fufficiently powerful for a theatre, or fpacious concert-room; but as a chamber-finger, both his voice and ftyle were exquifite. Previous to the arrival of Pacchierotti in England (1778), fignor Piozzi, who heard him at Milan, gave no *l'avant gout* of his performance, by finging feveral airs after his manner, in a ftyle that excited great ideas of his pathetic powers, and upon which fignor Piozzi feems chiefly, and very judicioufly, to have formed his own manner of finging.

PIP, in *Rural Economy*, a difeafe among poultry, confifting in a white thin fkin, or film, growing upon or under the tip of the tongue, which hinders the feeding. It has been fuppofed to arife from the drinking of puddle-water, or eating filthy meat, by fome; but this is not very probable. It is ufually cured by pulling off the film with the fingers, and wafhing the part with a folution of common falt in pure water. It is fometimes written *pep*.

PIPA, in *Zoology*, a fpeces of *Rana;* which fee.

Pipa, in *Commerce*. See Pipe.

PIPAREA, in *Botany*, a name of Aublet's, of which no explanation is given; but this omiffion is of fmall importance, the genus being almoft equally unintelligible. Aubl. Guian. v. 2. append. 30. Juff. 295.—Clafs and order unknown. Nat. Ord. fuppofed by Juffieu to be akin to *Ciftus*, or perhaps to his *Tiliaceæ*.

Eff. Ch. Capfule triangular, of one cell, and three valves. Seeds one, two, or three, clothed with cottony down, each inferted into a flefhy, white, fringed receptacle, attached to the middle of each valve.

1. P. *dentata*. Aubl. t. 386.—Gathered by Aublet in the forefts of Guiana, bearing fruit in Auguft. A fmall *tree*, whofe *trunk* is four or five feet high, and four or five inches in diameter, with a reddifh, wrinkled, rough bark. *Wood* hard, clofe-grained, whitifh. *Branches* fubdivided. *Leaves* alternate, nearly feffile, ovate, blunt-pointed, crenate, firm, feven inches long at the moft, and three wide; fmooth and fhining above; clothed with fhort reddifh down beneath; their midrib fending off numerous tranfverfe veins. *Stipulas* fmall, awl-fhaped, deciduous, in pairs at the bafe of the fhort *footftalks*. *Fruit* axillary, feffile, either folitary or in pairs, with two little fcales at its bafe, confifting of a thin, brittle, red *capfule*, fpotted with green, about as big as a filberd. The *feeds* are entirely covered with a very fine, pure white, cottony fubftance. Aublet never met with the *flowers*, nor has any fubfequent traveller given any account of this plant.

PIPARS, in *Geography*, a town of Hindooftan, in the circar of Joodpour; 20 miles S.W. of Meerta.

PIPE, a clofe channel for the conveyance of water, or other fluids, is of fuch extenfive ufe in building, &c. as to render the confideration of its materials, and beft means of forming its joints, a matter of importance to architects and engineers, that they may give ftability and durability to their work, at the leaft expence. Water-pipes are made of wood, iron, lead, copper, ftone, or pottery; and each of thefe materials, in different fituations, has its preference.

Wooden-pipes may be procured in all countries at a fmall expence, are eafily made, and joined together; but the great objection is their want of ftrength to refift a ftrong preffure without breaking, and their liability to decay. For water-works they are ufually made of elm, or alder; oak, though far preferable, being too expenfive. They are beft made from fmall trees of the proper fize; and then the bark, being left on, is thought to preferve them. The paffage is bored out by a long auger, turned round by one or two men; whilft the tree is fupported in a convenient pofition on treffels, and bound faft down upon them by ropes, to which weights are attached.

In towns where water-works are eftablifhed, the demand for pipes is fuch as to render this method too expenfive; and machines are ufed to bore them, turned by horfes, water, or fteam-engines. The pipe-boring machine is extremely fimple. A pit is firft dug, fimilar to a faw-pit; on each fide of this a long timber is fixed, and the two being united, at various points, by crofs framing, forms the bed, on which the fledge flides backwards and forwards as great a diftance as the length of the tree which is to be bored. The fledge is a frame of wood, upon which the tree is laid when it is to be bored, and is firmly held upon it by chains paffed over it, and drawn exceedingly tight with windlaffes fixed in the fledge. Wedges of wood are ufed to fupport it from rolling fideways, and to raife it up to fuch a height, that the borer will pafs through the centre of the tree. The borer is fixed at the extremity of a fpindle, fupported by bearings, on blocks raifed from the crofs framing of the bed at one end, and which are adjufted, that the line of the borer will be exactly parallel to the bed and fledge: the fpindle is put in motion by wheel-work from the mill, fo as to revolve 30 or 40 times *per* minute. The fledge with the tree is advanced towards the borer by ropes, which are conducted over proper pullies, from each end of the fledge, to the barrel of a wheel, with handles on its circumference, fimilar to the fteering-wheel of a fhip: therefore, a man, by turning

turning the wheel one way, advances the flider, with the tree towards the borer, which penetrates into the end of it; but on turning the wheel in an oppofite direction, it is withdrawn, to clear the chips of wood. This is repeated till the pipe is bored through. The borer can be detached from the fpindle, to employ another of greater or leffer diameter, when the pipes require it. The elm pipes employed in the ftreets of London for the diftribution of water, are made by this means, except fuch trees as are crooked: thefe are bored by hand augers, becaufe they muft be pierced from both ends to meet in the middle, which the machine will not readily do.

The lengths of pipe are joined together, by enlarging the bore at one end in a conical form, with a fort of auger, and cutting the oppofite end taper, to drive into the conical end of the adjacent pipe, which is hooped to prevent it from fplitting. This method is a very bad one, very foon decaying, even when the taper end is fitted perfectly, becaufe the thicknefs of the wood at the taper part is fo very fmall. In the ufual mode of fitting them, by merely fhaping the conical part with the axe and drawing-knife, whilft the workmen are perhaps over fhoes in mud, and expofed to bad weather, it is fcarcely reafonable to expect them to be very attentive; but the joint is fitted in hafte, and difpatched as quick as poffible: the confequence is, that the conical part being correctly bored, whilft the taper is made to an irregular and more obtufe cone, the joint fits only at a very narrow point; but if well driven, will make a tight fitting at firft, and, when buried, efcapes detection; but in the courfe of a very few years, the vacant fpace round the end of the taper accumulates mud, which haftens the decay of the wood, and the joint fails. From thefe circumftances, the pavement of the ftreets is conftantly broken up, the way impeded, and the fupply of water fufpended. The Society of Arts have, under thefe confiderations, offered a handfome premium, for feveral years paft, to procure a complete remedy for thefe defects. Mr. Hornblower propofed a tool, or bit, to form the taper end of the pipe, with the fame certainty as the cone which is bored. It confifted of a wooden plug, fitted to the bore of the pipe, and having through its centre a hole, for the reception of a round iron rod or axis, which has a crofs handle at the end, like an auger, to turn it round by. Near the handle, its fize is fufficiently enlarged to have a mortife, for the admiffion of an iron arm, which can be fixed in it by a wedge. This arm turns down, and carries a fteel knife, the edge of which, by the bending, ftands inclined to the round rod, in the angle the conical taper is to have: therefore, by turning the handle round, the edge of the knife defcribes the furface of the cone, and cuts away the wood of the pipe to that form; the round rod, being of confiderable length, can flide freely in the plug at the end of the pipe, and allow the cutter to be thruft up, to cut by degrees, till it reduces the taper. The ufe of this tool would enfure the perfect fitting of the joints; but ftill the plan is defective, as before mentioned, from the fmall quantity of wood round the joint. Another kind of joints have, therefore, been propofed: in thefe the adjacent ends of the pipes to be joined are both bored out, by a taper bit, to hollow cones; and the two are united by a fhort iron tube, which is made in form of two truncated cones joined at their bafes, and of dimenfions correfpondent with the conical bafes in the ends of the pipes. This plan is very far preferable to the former, both in ftrength and durability; and as the tubes are made of caft-iron, it is not an expenfive one.

Meffrs. Eckhardt and Lyon obtained a patent in 1806, for a method of making wooden pipes by feparate ftaves, resembling a barrel, but of lefs curvature, and greater proportional length, fo as to approach near to a cylindrical form, particularly withinfide. They are to be bound by iron hoops, made faft either by driving them on from the ends, or by fcrewing the hoops together; the lengths are to be joined together, by forming one end of each taper, and enlarging the correfponding ends of others to receive them: the ftaves are to be fitted by tongues, rabbiting, or dovetailing. We have not heard of this method having been practifed to any extent: it would, we think, be very expenfive, and have all the defects of wood pipes; being liable to fpeedy decay, when buried in the ground. And it generally happens, that in their rotten or decayed parts they generate infects and animalculi in vaft numbers; which may always be difcovered in water that has paffed through wood pipes or pumps, which have been long in ufe. Dr. Buchan obferves, that fuch water becomes putrid by the corruption of the animal and vegetable bodies with which it abounds.

Iron-pipes are caft at the iron-founderies of any dimenfions; and for durability and ftrength combined, are greatly fuperior to any other material: they may be procured in lengths of ten feet, and united by nuts and fcrews paffed through flaunches, caft on the ends of them. Moft of the great Companies for fupplying London with water have, within thefe few years paft, adopted caft-iron pipes for their mains, and are daily increafing them, under the conviction that their permanency will compenfate for the firft expence. They are ufually caft in lengths of ten feet, one end with an enlarged focket of fufficient fize to receive the end of the next pipe. As thefe joints cannot be driven clofe, to fit like wooden joints, they require fome cement. To apply this, they firft caulk it, by driving a fmall quantity of hemp down to the bottom of the joint with a blunt chiffel, and then fill the remainder of the focket with iron cement; which is a compofition of borings or turnings of caft-iron, mixed up with fulphur and fal ammoniac. This is moiftened with water, and rammed into the cavity; and the rapid oxydation of the iron borings unites them into one mafs, and at the fame time expands the bulk of the cement, fo as to fill up all the fpace very clofely. The hemp, firft driven into the joint, is only to prevent the cement getting into the pipe, and to keep the water from it till it is fet firmly; after which, the joint is as folid as any other part of the pipe. Another method, much ufed for large pipes, is to have two ears projecting from each pipe at the joint, through which fcrew-bolts are paffed, to draw them clofe together. The joints are fometimes filled with lead run in, whilft melted; and others have ufed the Roman cement to bed the joints in.

Within thefe few years immenfe quantities of iron pipes have been laid in all parts of London, for the conveyance of water, which no fooner became generally known, than great prejudices were excited againft them, under the idea that they would give the water a metallic tafte, which would be injurious to the health of the inhabitants. This is clearly an error, as any one may afcertain, by examining an old ciftern, or veffel of caft iron, which has only had frefh Thames water in it; and they will find it coated with a fort of japan, or fmooth furface of a black colour, which is a very thin oxyd, and does not penetrate any depth: though if the water is of fuch a quality as to produce red ruft, the iron is corroded very faft, but is ftill a very harmlefs mixture. Water having any lime in it, depofits a thin coat or incruftation withinfide iron pipes, and thus completely defends them from corrofion; nor is there any danger, as fome have fuppofed, of this incruftation increafing fo ſo as to ſtop the pipes in courſe of time, becauſe the water only depoſits the ſtony matter from the attraction of the iron, which being once covered with a ſlight thickneſs, the water has no longer acceſs to the iron. We have heard of an expedient of putting lime into the water, when it was found that the water was ſo corroſive as to become tinged by running through iron pipes newly laid down. A rapid current of this lime-water being cauſed through the whole length for a few days, the pipes became coated with the calcareous matter. At firſt, after this, the freſh water taſted of lime, but it became pure in a ſhort time, becauſe, in the firſt inſtance, more lime was depoſited than could be combined with the oxydated ſurface of the iron, and this exceſs would of courſe be carried away again by the freſh water, but no more.

Stone Pipes.—The prejudice the public at firſt entertained againſt iron pipes, induced many projectors to find out other ſubſtances, which would have the ſtrength and durability of metal. Sir George Wright propoſed ſtone, and invented a machine for cutting out cones from the hollow of the pipe. He firſt employs a boring or drilling machine, to pierce a ſmall hole through the centre of the block of ſtone, in the axis of the intended pipe. Another machine is then uſed, conſiſting of a ſaw applied in a frame, which revolves on a round iron rod, paſſed through the central hole previouſly drilled: the frame gives the means of fixing the ſaw at any required diſtance from the rod, and attaching it firmly thereto at each end: its edge will of courſe, when turned round, deſcribe the ſurface of a cylinder, of the diameter of the intended pipe. The ſaw and central rod are rather longer than the block of ſtone, which permits them to be moved backwards and forwards endways, to give the motion of ſawing with ſand and water in the uſual manner. In their operation, the block of ſtone is placed with the rod horizontal; the ſaw is entered at another hole, previouſly drilled through the ſtone, and as the ſaw cuts, the central rod guides it round on a centre, till it ſeparates the core all round, and this being taken out, leaves a pipe or tube. Sir George obtained a patent for this invention in 1805, and it was practiſed for ſome time, and many large ſtone pipes were laid; but great difficulties aroſe in making good joints: they were attempted by Roman cement, which adhered ſo well, as to make them perfect, if the pipes were well bedded; but the continual tremor of heavy carriages paſſing over them ſoon diſturbed many joints, and broke the bond of the cement. Mr. Samuel Hill took out a patent in 1810, for uniting theſe pipes together at every joint by a collar of ſtone, into which the extremities of two pipes are made to fit, ſo that about two inches of each ſhall enter it, and reach to its centre, where they are to meet. A ſufficient quantity of cement is to be ſpread on the ends of each pipe, and in the internal part of the collar, before they are inſerted into it, to prevent water from paſſing through the joints. Although this obviates one difficulty, ſtill the expence of ſtone pipes is prodigious; at leaſt in London, where the price of materials alone, without any coſt of workmanſhip, would be too great. In ſituations where that material is plentiful, they may be uſed, and the labour of making them will be reduced very low by a machine invented by Mr. Murdoch, and for which he had a patent in 1810: it is very ſuperior to the above, which is only applicable to large pipes; beſides, the trouble of previouſly drilling two ſmall holes the whole length of the pipe is wholly ſaved.

When it is intended to form a pipe or hollow cylinder of ſtone by Mr. Murdoch's machine, inſtead of reducing the whole inſide to powder, it is ſawed in the form of a core, or ſolid cylinder, the diameter of which is about half an inch leſs than the diameter of the inſide bore of the pipe. In like manner, when a ſolid column or cylinder is to be formed, the outſide and ſuperfluous parts of the ſtone are taken away by a ſimilar proceſs, and the core forms the column or cylinder required. When the ſtones are large enough to leave the outſide parts of a proper thickneſs, they may be uſed as pipes; or the cores cut out of large pipes may be uſed as columns, or formed into ſmaller pipes, ſo that in ſome caſes ſeveral may be cut out one within another. The method by which theſe are formed is the following:

The block of ſtone, out of which the pipe is to be formed, is placed in a vertical poſition, and a plug of wood or metal is fixed in the top of the block, at the centre of the intended pipe; this plug has a hole in its centre, for receiving the lower pivot of a vertical ſpindle or axis, which is made longer than the pipe is required to be. The rod is of an uniform thickneſs, and made either ſquare, triangular, or any other ſhape that will admit of ſockets ſliding freely up and down, without turning round upon it. On the upper part of this ſpindle a ſocket is fitted, having on the middle part of its outſide a pulley or a ſmall-toothed wheel, by which the axis or ſpindle may be turned round. The upper and lower extremities of this ſocket are cylindrical, and ſerve as gudgeons, upon which it turns in a frame, and ſteadies the axis. Near the lower end of the vertical axis a wheel with arms is fixed, having the circumference like a hoop two or three inches broad; and its diameter a little leſs than the diameter of the pipe to be bored: it fits to the inſide of a tube of metal, which is attached to the ſpindle, and kept concentric with it, by being fitted over the wheel. The upper part of the ſpindle is perforated to a little below where the above-mentioned ſocket is fixed, and then the perforation comes out obliquely. The tube is of a diameter nearly equal to that of the pipe to be formed, and exceeding it in length about two feet: this pipe is made as truly cylindrical as poſſible, and is attached to the axis by another wheel acroſs, ſimilar to that at the bottom, which is fixed in the tube at the upper end, and fits upon the ſquare ſpindle, to ſlide freely up and down, without turning round upon it; this tube being, as before-mentioned, guided by fitting on the wheel fixed at the lower part of the ſpindle. On the lower edge of the tube a rim of proper metal is fixed, which is ſo much thicker than the tube, that the groove it makes in the ſtone may admit the tube to move freely. This hoop being intended to grind or ſaw the ſtone, has its lower edge either left ſmooth, or formed like the ſaws uſed by ſtone-cutters. The wheel or croſs, which is fixed on the vertical tube, near its upper end, has a ſmall cord or chain faſtened to one of its arms, and paſſes upwards through the perforation in the upper part of the axis, and then over a pulley fixed at a convenient diſtance above it: it ſerves to raiſe the tube on its axis when required. On the upper part of the tube weights are fixed, for the purpoſe of making it act more forcibly upon the ſtone, if neceſſary. When the apparatus is to be put in motion by the force of man, the above-mentioned pulley, fixed in the ſocket near the upper part of the axis, is generally made about double the diameter of the pipe to be bored, and a rope paſſes round it, each end of which is conducted over a vertical pulley, fixed at a convenient diſtance, on each ſide of the machine; by which means the ends of the rope turn downwards, and having handles fixed to them, are pulled alternately by a man at each end, ſo as to cauſe the tube to make a reciprocating rotative motion about its axis or ſpindle: or the apparatus may be put in motion by any other power, only if the pulley and cord be retained, a ſpring or a ſufficient weight acts at at one end, while the power operates on the other by means of a crank, or other fimilar contrivance. Or, inftead of the pulley, a toothed wheel or pinion is fubftituted, and acted upon by a reciprocating toothed wheel, belonging to the mill, engine, &c. connected with the moving power, or by a reciprocating rack or fector, put in motion by the fame power or machinery. A ciftern is placed at fome convenient height above the tube, by means of which, a mixture of water and fand is conveyed into the tube, and forces its way under the faw, when in motion, and caufes it to abrade or grind away the ftone, and form in it a circular groove, concentric with the axis. As the groove becomes deeper, the water accumulates in the tube, and forces the fand with it under the faw and both are difcharged over the outer edge of the tube, in the form of mud or fludge, and the motion of the tube may be thus continued as long as the moving power is maintained. When any circumftance caufes this to ftop, the tube muft be drawn up by means of the cord and pulley for that purpofe, or the fand will fet faft round the tube, and will not be eafily freed again.

Copper-pipes are too expenfive to be employed except in particular fituations. They are made of copper plate turned up and foldered, and are much ufed in diftillers' work, becaufe they can be tinned withinfide, and then communicate no taint to what paffes through them.

Lead-pipes are univerfally employed for all fmall water pipes, chiefly from the facility of bending them in any direction and foldering their joints. Although fome kinds of water corrode the metal by degrees, this will not produce fo much harm as iron under the fame circumftances, but would be a moft dangerous poifon if it was ufed in fufficient quantities to have any effect at all.

The greateft proportion of the leaden pipes ufed in waterworks, was, till of late years, made of fheet lead wrapped round an iron or wooden core, and the joint foldered up. The expence and trouble of this method was confiderable, and the pipes thus made extremely liable to burft at the joint, particularly if bent with a fudden angle. Thefe defects fuggefted the idea of cafting the lead in the form of pipes, by which means the trouble of previoufly cafting and laminating the lead into fheets would be fpared, and alfo the uncertainty of the foldered joints. Such pipes are caft in an iron mould, made in two halves, forming, when put together, a hollow cylinder, of the fize of the intended pipe. A core, or iron rod, the fize of the bore of the pipe, is adapted to this hollow mould when the halves are put together, and fecured by fcrews or wedges, fo that it exactly occupies the centre of the hollow mould, leaving therefore an equal fpace all round between them. A fpout, or entry for the admiffion of the melted lead, is made by a correfponding notch cut in each half of the mould, and at another place is a fimilar vent for the efcape of the air. This mould is fixed down upon a long bench; and a rack, moved by toothed wheels and pinions, is fitted up at one end of it, in a line with the centre of the mould. A hook at the end of the rack, being put into an eye at the end of the core of the mould, affords the means of drawing out the core, when the pipe is caft round it by pouring the melted lead into the mould, with the core in it: when the lead is cold, the core is drawn out very nearly to the end of the pipe, by the rack and wheel-work before mentioned. The halves of the mould are then feparated, and the pipe moved along in the mould, fo that only an inch or two of its end remains in the mould, the halves of which are again faftened together with the core between them, and its end entered an inch or two into the firft piece of pipe. The mould is now filled with melted lead, the heat of which fufes and unites it with the end of the firft piece, fo as to double its length. The core is again drawn out a fecond time, and another length caft to the former. This method produces pipes of any length in one piece, but they are liable to have air-bubbles in them, which produce holes when the metal is thin, and the joinings of the different lengths are not always perfectly found.

The method which is now very generally adopted, is to caft the lead in an iron mould, upon a cylindrical iron rod of the fize for the bore of the intended pipe, the lead being three or four times the thicknefs of the intended pipe, and in fhort lengths, which are then drawn through holes in pieces of fteel, in the manner of wire drawing, till the pipe is reduced to the intended thicknefs, and drawn out to the proper length. Another method is to reduce the pipe by repeatedly paffing it through the two rollers of a flatting mill, in each of which a number of femi-circular notches are formed all round, fo that the two rollers, when put together, have a number of circular cavities between them, which gradually diminifh in diameter from one end of the rollers to the other. Drawings of fuch rollers will be found in our plates of *Iron Manufacture*. The pipe is firft rolled between the largeft of thefe cavities, then in a fmaller, and fo on to the laft, which extends the pipe to its proper length, and diminifhes its fubftance to the proper thicknefs, at the fame time by condenfing the metal hardens it, and makes a very ftrong tube with very little metal. Mr. John Wilkinfon of Brofely, the celebrated iron manufacturer, took out a patent, in 1790, for the laft mentioned method, which he practifed on a very extenfive fcale: he was not, however, the original inventor, the fame thing having been propofed, in 1728, by M. Fayolle; fee "Machines Approuvés par l'Academie Royale," vol. v. p. 50. Since the expiration of this patent many manufactories of this article have been eftablifhed, fome employing rollers, and others the draw-bench, for extending the pipes.

We have given a reprefentation of one of the latter machines in *Plate* XL. *Mechanics*. *Figs*. 1 and 2 are fections of the mould for cafting the pipes; A A is the bench, fupported on legs like a ftool in an inclined pofition; B, B, are the two halves of the mould, fitted into each other with double rebates, as fhewn in the fection *fig*. 1, that they may come together correctly, and are held fo by the fcrews D, D, fitted through pieces of iron E, E, faftened to the bench; the halves of the moulds have at each end a flat fide beneath, which refts upon the iron plate connecting the two pieces E, E; F is the core, held in its pofition by collars at each end of the mould embracing it; G is the rack, and H I K the wheel-work for drawing out the core; *d* is the entry for the metal, raifed up to the fame level as the higheft point the metal is intended to run into. The intention of the inclined pofition for the mould is, that the metal may run in at the loweft point of the mould, and expel the air as it rifes, at a vent in the higheft point of the mould, which is *e*. By this means the danger of air-bubbles in the pipe is avoided. The interior furface of the mould is bored out truly cylindrical, and the core being turned in the lathe, they are certain when put together to leave an equal fpace all round, a circumftance which is effential to form a good pipe, as the fucceeding procefs of drawing will tend to make an error of this kind worfe. The core, F, is feen in *fig*. 2 to have a neck or fmaller part at the end *d*: the treblet or core *a g*, *fig*. 3, upon which the pipe is to be drawn, is of the fame fize, and has a fimilar neck, fo that the pipe, when put upon it, fits it in every part, as is fhewn in *fig*. 3, and the fhoulder of the neck prevents the treblet being drawn through the pipe in the direction from *g* to *a*, as it was put in by the oppofite direction. Beyond the neck the treblet has a notch cut in each fide at *g*, leaving a neck;

a neck; and by this it is feized in a fort of claw belonging to the draw-bench, which is exhibited in *figs*. 4 and 5, the former being a plan, and the latter a fection. In thefe L, M, are two ftrong timbers, bolted to uprights N, O, at one end of each, and to a crofs beam, W, at the other end; the uprights fupport bearings for the gudgeons of a ftrong iron fpindle, which has the cog-wheel, *k*, fixed upon its end, and is turned round by the pinion *l*, receiving a rotative motion from a fteam-engine or water-wheel; P is a roller, fitted on the fpindle fo as to flip round freely upon it; it has two claws affixed into it at one end, which are feized by the ends of an iron bar, *m*, fixed faft upon the fpindle. By this means, when the roller is thruft towards *m*, it is engaged with its arms, and compelled to turn round with the fpindle, but when drawn back from *m*, it is at liberty to flip round independent of it; Q is a lever affixed to a vertical axis; it is forked at the end, and embraces a collar upon the end of the roller, fo as to draw it backwards or forwards, and by this means engage or difengage it from the fpindle at pleafure; R is another lever on the fame fpindle, to the end whereof a long rod, S, is jointed, and this has feveral handles fixed to it, as fhewn in *fig*. 5, by which it can be moved, and the machine ftopped or put in motion by a man ftanding at any part of the long bench L M; the roller, P, has a pair of fpiral grooves formed on its circumference, for the reception of two chains, *n*, *n*, which wind upon it; the ends of thefe chains are hooked to a little carriage, *p*, running upon two wheels, and having in its hinder part a fork or double claw, to catch in the notches at the end of the treblet T, alfo fhewn in *fig*. 3; X is a caft-iron frame, fecurely bolted down upon the crofs beam W; it has a notch in its upright fide, which is neareft the roller, to allow the treblet and pipe to pafs through, but at the fame time forms a lodgment for the fteel plate, through which the pipe is to be drawn. The workmen are provided with a great number of thefe plates, one of which is fhewn in *fig*. 6; they are called whirtles: the fizes of the holes through them diminifh very gradually, from the diameter of the rough caft pipe, to the fize to which it is intended to be reduced. The holes through them are made rounding at each fide, as is fhewn in the fection Z, *fig*. 6, to facilitate the exit and entry of the pipe. The bench is continued beyond the beam W, and has a number of rollers in it, to fupport the pipe as it is drawn along.

The procefs of drawing is as follows: the lead pipe being fitted upon the treblet, as in *fig*. 3, is laid upon the rollers in the bench, and the end of the treblet being put through the largeft of the fet of whirtles, its end is hooked into the claws in the carriage *p*, and the whirtle lodged againft the cheeks of the frame X: the rod, S, is now pulled, which engages the roller with the fpindle (fuppofed to be all the while in motion); this winds up the double chains *n*, drawing the pipe through the whirtle, by which it diminifhes its fize and lengthens it out: when the pipe is drawn quite through, the roller is caft off by pufhing the rod S; the treblet is unhooked from the carriage, and pufhed back upon the rollers in the bench to its former pofition; another fmaller whirtle is put on; the carriage is drawn back by hand (the roller turning round on its fpindle), and the pipe is drawn through it as before. In this manner the bufinefs proceeds till the pipe is finifhed.

Sometimes the pipe is drawn through twelve fized whirtles in this cafe; the fecond time, and alfo the laft time but one, it is drawn through a whirtle fuch as Y, *fig*. 6; it is not rounded off at the entrance, but having a fharp edge, it cuts off fhavings from the furface of the lead, making it perfectly fmooth and true: this makes it pafs more eafily through the fucceeding whirtles. Lead pipes are by this procefs drawn out to ten or twelve-feet lengths, three of which are united into one, by what is called *burning*. For this purpofe an iron core is put through one pipe, and entered a few inches into the other: a fmall iron mould is now put together in two halves over the ends of the two pipes which are brought in contact, the mould exactly fitting both; melted lead is poured into the mould, and it runs out again at a hole in the bottom. This is continued till it is fuppofed the heat of the lead has fufed the ends of both the pipes; the hole in the bottom is then ftopped by a flider for the purpofe, and the mould remains full: when cold it is taken off, and the pipes are perfectly united. The core is now withdrawn, to facilitate which, it only fits the bore of the pipe at a few inches of the end. Thefe joints are very good if the pipe remains ftraight, but are apt to leak if a bend is made at one of them.

In 1804, Mr. Alderfon took out a patent for lead pipes which were to be lined with tin, for the conveyance of beer, water, or other fluids which were in danger of receiving a taint from the corrofion of the lead. This he accomplifhed by cafting a lead pipe in the manner above-defcribed, then withdrawing the core, and throwing into the pipe a fmall quantity of powdered rofin. Another core fmaller than the former is next inferted into the centre of the pipe, and melted tin poured in to fill up the fpace. The pipes are caft in a vertical pofition, and the rofin melting by the heat floats upon the furface of the tin, and acts as a flux to unite it with the lead. This pipe of lead, lined with tin, is now to be drawn or rolled to length, as before-mentioned. We are informed Mr. Alderfon employs rollers to extend them inftead of the draw-bench.

Mr. Bramah's method of making lead pipes is very ingenious; it is performed by a procefs of pumping or forcing the metal, in its fluid ftate, through proper moulds. A boiler or kettle is fitted up over a fire-grate, with flues for the fufion of the metal; in the centre of this boiler a force pump is fixed up, its fuction valve drawing in the melted lead contained in the boiler: the forcing pipe of the pump proceeds through the fide of the boiler, and conducts the lead to the mould, which is fixed on the end of the pipe outfide of the boiler: it confifts of a tube, bored perfectly fmooth and cylindrical, its interior diameter being equal to the outfide of the pipe intended to be made; the end of the mould neareft the boiler expands into a conical mouth, larger than the mould itfelf, and acrofs this wideft part a crofs bar is fixed, to fupport a core or mandrel, of a diameter equal to the bore of the intended pipe, and fituated exactly in the centre of the mould, leaving an equal fpace all round between them: the core is flightly conical, being rather lefs at its extremity, which terminates at the fame length with the external mould. There muft be fufficient openings left at the fides of the crofs bar fupporting the core, to allow the lead to pafs freely by, that it may unite again after paffing the crofs and completely fill the mould. The mould paffes through one of the fire flues furrounding the boiler, that it may be kept fo hot as to procure the lead in its fluid ftate, till it arrives nearly at the point of the mould, which is immerfed in a ciftern of hot water. The operation is fimple: the pump, being worked, forces the lead through the mould, the heat and length of which are fo regulated, that the lead may chill a little before it quits the extremity of the mould, and iffues forth in a folid ftate into the water ciftern, forming a pipe of any length. Mr. Bramah took out a patent for this method in 1797.

Pipes of pottery ware are ufually made of that coarfe kind of brown ftone pot, which is very hard and durable; they can only be made in fhort lengths, and have one end enlarged to receive others. To close the joints tow and pitch are used, but they can never be made to bear any pressure, are liable to be broken by accident, and being very expensive, have no other recommendation than preserving the purity of the water they convey.

We have seen some water conduits from an old Roman building, which were very slight pottery tubes, buried in a mass of mortar, that by ages had acquired a hardness and closeness sufficient to resist a strong pressure.

In 1808 Mr. W. Bell obtained a patent for a new kind of pipes for conveying water, which were to be made of such substances as to give no taint to the water passing through them. He proposed tubes of porcelain pottery, and various compositions which are vitrifiable, and are not liable to corrosion or decay: these tubes are formed in such a way at the ends as to fit one within the other, and are to be made water tight by cement; they are to be enclosed in cast-iron cases, to give them strength to resist the internal pressure of water, as well as to defend them from accidental violence; or the cases may be made of wood.

Pipe, *Tobacco*, an implement used in the smoaking of tobacco, consisting of a long tube, made of a particular kind of clay baked hard: at one end a little cavity or furnace is formed, called the *bowl*, which is for the reception of the tobacco when burning, and the fumes are drawn by the mouth through the other end of the tube. The making of tobacco pipes forms a considerable trade in London and other great towns; they are made of various fashions, long, short, plain, worked, white, varnished, unvarnished, and of various colours, but the same process is followed for all of them. The clay is found in the isle of Purbeck, in Dorsetshire, and is distinguished from others by its perfect white colour, and its great adhesion to the tongue when baked, occasioned by its great affinity for water: even in the raw state it has this property in a slight degree. The clay is prepared by dissolving it in water in large pits, and the solution being well stirred, is run off into another pit, where it deposits the clay, which, when the water has become clear and run off, is taken up for use, all impurities of small stones, sand, &c. being separated from it and left in the first pit. The clay is now divided into portions, each sufficient to form one pipe, which are rolled on a table, under the hand, into long rolls, each with a bulb at the end, to form the bowl; and these are laid by a day or two, to dry sufficiently for the pressing. This is done in an iron mould, consisting of two halves, which when put together leave a cavity of the shape of a pipe; a wire is thrust up the roll of clay, to form the bore of the pipe, and in this state it is placed between the two halves of the mould, which are then put into a kind of press or vice, by the screw of which the two halves are forced together, and the figure of the pipe imprinted on the clay included between them; a lever is next brought down, which is so situated as to introduce a stopper into the bowl of the pipe whilst still in the mould, and force it down sufficiently to form the cavity thereof: the wire is thrust backwards and forwards, to prick the tube completely into the bowl; it is then wholly withdrawn, the parts of the mould separated, and the pipe taken out, the superfluous clay removed with a knife, and they are laid up to dry a day or two, after which they are scraped and polished with a piece of hard wood, the tubes of the pipes curved as they are intended to be, and they are then carried to the furnace to bake, which is done in seven or eight hours for fifty gross of pipes. This furnace is fully described at the end of our article Furnace.

The Turks use pipes of three or four feet in length, made of rushes, or of wood, bored at the end; they have a bowl or pot of baked earth to contain the tobacco, which they separate from the tube when they leave off smoking. To make the tube tight, some kinds are made of spiral wire covered with leather. This at the same time leaves them flexible, and the bowl can stand on the ground, whilst the smoker inhales its fumes through an ivory or silver mouth-piece at the end of the tube. Of this kind is the *hookah*, or *houkar*, used by the luxurious East Indians; it is a complete furnace or chafing-dish, with grate-bars, ash-pit, &c.; and has a tight cover over the top, with one of these flexible pipes attached to it. An officer of the court of a petty eastern prince is called *houkar boudar*, and is solely employed in managing this machine; which, having lighted and prepared, he presents the mouth-piece of the tube to his master after his dinner. In some instances, the bowl is kept in an adjacent closet, the pipe being conducted through a hole in the wall. Some of those which are most complete have another peculiarity; the smoke, before it goes into the tube, is made to pass under water, by bubbling up through it. This is found to give the smoke a mild and agreeable flavour, by depriving it of its acrid and pungent taste; and, indeed, it is for the same end of condensing these particles, that the tubes are made of such great length. We are not informed how the smoke is made to pass under the water, but have seen a simple experiment, which any one may try, to experience the improvement of the smoke by this process. Procure a common decanter or glass bottle, fill it half full of water, and fit a cork to it, which has two holes made through it by burning, sufficiently large to admit tightly the tube of a tobacco pipe: in one of the holes fit a pipe with a bowl, the tube end projecting so far down into the bottle, that it will be an inch below the surface of the water: into the other hole, fit a pipe without a bowl, not reaching to the water, but sufficiently curved or inclined to come conveniently to the mouth. Make all the joints tight by wax, fill the bowl of the pipe with tobacco, and light it; then by sucking air through the mouth-pipe, it will be drawn out of the bottle, and rarefy that within; the atmospheric air then presses through the burning tobacco in the bowl of the pipe, and carries the smoke down the tube through the water, and it rises in bubbles to the surface of the water in the bottle, from whence it can be inhaled through the mouth-pipe, by continuing to suck at it. The smoke is by this process cooled, and rendered very agreeable, by the separation of certain principles which are of a very unpleasant flavour: the existence of these principles will be shewn by the water in the bottle becoming yellow in a short time, and having a very disagreeable taste. This method of smoking may be useful to invalid smokers, who from cough, or inflammation of the lungs, are unable to continue a practice which, by long habit, has become quite an essential comfort to them.

Pipe, in *Commerce*, a measure of wine in England, Spain, and Portugal. (See Measure.) The pipe is = $1\frac{1}{2}$ puncheon = 2 hogsheads = 3 tierces = 126 gallons = 504 quarts = 1008 pints; and 2 pipes are equal to a tun of wine. The standard gauge for foreign wines at the custom-house of London is as follows: the pipe of port is 138 gallons; of Lisbon, 140; of Madeira, 110; of Barcelona, 120; of Vidonia, 120. The butt of sherry is 130 gallons, and of mountain, 120. The hogshead of claret is 58 gallons, and of tent 63. The aum of hock is 36 gallons. The gallon used here is seven inches in diameter, and six inches deep. The tonnalada of Lisbon is 2 pipas; the pipa is 26 almudes, 312 canadas, or 1248 quartillos. The baril is 18 almudes. The pipe of the standard gauge of Lisbon at the London custom-house is reckoned at 31 almudes, and the almude

almude at $4\frac{1}{2}$ English gallons nearly. A pipe in Spain is 27 arrobas of wine, or $34\frac{1}{2}$ of oil; and as a Spanish botta contains 30 arrobas of wine, or $38\frac{1}{2}$ of oil, the botta is $= 127\frac{1}{2}$ English gallons, and the pipe $114\frac{3}{4}$.

Pipe, *Pipa*, in *Law*, is a roll in the exchequer, called also the *great roll.*

Pipe-*Office*, is an office in which a person called the *clerk of the pipe*, makes out leases of crown lands, by warrant from the lord-treasurer, or commissioners of the treasury, or chancellor of the exchequer.

Clerk of the pipe makes up all accounts of sheriffs, &c. and gives the accomptants their *quietus est.* To this office are brought all accounts which pass the remembrancer's office, and remain there; that if any stated debt be due from any person, the same may be drawn down into the great roll of the pipe, from the form of which he derives his name; upon which the comptroller issues out a writ, called the "summons of the pipe," for recovery thereof. And if there be no goods and chattels, the clerk then draws down the debts to the lord-treasurer's remembrancer, to write estreats against their lands.

All tallies, which vouch the payment of any sum contained in such accompts, are examined, and allowed, by the chief *secondary of the pipe.*

Besides the chief clerk, and his deputy, in this office are a first and second secondary, six attornies, or sworn clerks, and a comptroller, deputy and clerk, board-end clerks, and bag-bearer.

Pipe, in *Mining*, is where the ore runs forwards endways in a hole, and doth not sink downwards, or in a vein.

Pipe, *Air.* See Air-*pipe.*

Pipe, *Bag.* See Bag-*pipe.*

Pipe-*Clay.* See Clay.

Pipe-*Clay* and *Whiting*, in *Military Language*, a composition which soldiers use for the purpose of keeping their cross-belts, &c. clean. Every soldier belonging to the infantry of the line, and to the fencible infantry serving at home, has 4*s.* 4*d.* annually stopped from his pay for supplying himself with this composition.

Pipe-*Drains*, in *Agriculture*, such as are made in the more superficial parts of the earth, as a foot or more from the surface, by means of some sort of tool or implement, such as a thick iron spike, pin, or bolt, which is drawn through the ground in a horizontal manner at such depths. The improved mole plough is a very good tool for effecting these purposes, and is that which is most commonly employed in the business.

This is an excellent method of management for cold retentive grass lands, which lie in too flat and swampy a manner to shoot off their surface waters, with any degree of readiness, and which are free from stones. But though it may be found of general benefit in these cases, it is more especially so, it is conceived by some, for moist sheep pastures; it has also been found useful in some instances in arable land. When it is performed by the plough just noticed, the great strength and weight of draught which are required, especially where the older sorts of these ploughs are had recourse to, may form some objection to it. These tools have, however, much merit, and are very simple in their constructions, particularly the improved kinds, which only demand a little power of draught. See Mole Plough.

Pipe-*Fish*, in *Ichthyology.* See Acus and Syngnathus *Typhle.*

Pipe, *Horn.* See Horn-*Pipe.*

Pipes, *Organ.* See Organ.

Pipe, *Tail*, in *Gunnery*, a small brass pipe fixed at the swell of the musket, which receives the ram-rod.

Pipe, *Trumpet*, a small brass pipe near the muzzle of the firelock, through which the ram-rod is let down; so called from its resemblance to the mouth of a trumpet. The Prussians have no pipes to their muskets; the ram-rod being received into a cylinder which runs parallel with the barrel.

Pipe-*Tree*, in *Botany.* See Philadelphus and Lilac.

Pipe-*Tree*, *Pudding.* See Cassia.

PIPELGONG, in *Geography*, a town of Hindoostan, in Baglana; 14 miles N.W. of Chandor.—Also, a town of Hindoostan, in the circar of Aurungabad; 32 miles W. of Aurungabad.

PIPELO, a town of Hindoostan, in the circar of Rantampour; 33 miles W.S.W. of Rantampour.

PIPEMAKER's Creek, a river of the state of Georgia, which runs into the Savannah, N. lat. 32° 8′. W. long. 81° 15′.

PIPER, in *Botany*, Pepper, is enumerated by Linnæus, among the Greek names of doubtful origin. The Greek πεπερι is generally supposed to have been derived from πεπτω, *to cook*, or *digest.* But the best authors give it as a primitive word; and professor Martyn rightly suggests that it is probably of Indian origin. De Theis also observes, that as the Greeks derived the knowledge and use of pepper from the oriental nations, the source of its name is to be sought in their languages, and its appellation in Arabic, *bâbâry*, is the evident original of πεπερι.—Linn. Gen. 19. Schreb. 26. Willd. Sp. Pl. v. 1. 159. Vahl. Enum. v. 1. 312. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 69. Juss. 405. Lamarck Illustr. t. 23. Gærtn. t. 92. (Peperomia; Fl. Peruv. v. 1. 29. Saururus; Plum. Gen. 51. t. 12.)—Class and order, *Diandria Trigynia.* Nat. Ord. *Piperitæ*, Linn. *Urticæ*, Juss.

Gen. Ch. *Cal.* none. *Cor.* none. *Stam.* Filaments none; anthers two, opposite, at the base of the germen, roundish. *Pist.* Germen larger than the anthers, ovate; style none; stigmas from one to three, rough. *Peric.* Berry roundish, of one cell. *Seed* solitary, globose.

Eff. Ch. Calyx none. Corolla none. Berry with one seed.

A very extensive and singular tropical genus, remarkable for the simplicity of its *flowers*, which almost vies with that of the *Hippuris.* The number of *stamens* however is, in some cases, more than two, and in some the *stigma* is solitary. Several botanists have taken the *flower* to be gynandrous, because, at a very early period, before the *germen* is fully formed, the two *anthers* look as if seated on its summit, close to the *stigma*; but Jussieu well observes that they become lateral, or rather inferior, as it advances towards maturity. Linnæus has but twenty species of *Piper* in the second edition of Sp. Pl. to which five only are added in Syst. Veg. ed. 14. Willdenow has 52; but the most complete botanical view of this genus is found in Vahl's Enum. Plant., where 136 species are defined, and well described. This author properly unites the *Piper* and *Peperomia* of the Flora Peruviana, there being no solid generic difference between them; and he gives the following excellent sketch of the habit.

Stem round. *Leaves* simple, undivided, entire. *Spikes* lateral and terminal, stalked, simple, round. *Flowers* minute, crowded. *Sheaths* deciduous. In the first section, consisting of 73 species, the *stem* is shrubby, climbing, branched, jointed; the joints more or less knotty, and often sending forth roots: *leaves* stalked, alternate; some of them furnished with many nerves, proceeding, in alternate order, from the main rib, (Vahl terms such species *venoso-nervosi*); others having almost all the nerves originating from the base of the leaf (these he calls *nervosi*): *footstalks* channelled,

with

with a clafping bafe: *fpikes* oppofite to the leaves, and moftly folitary. The fecond fection comprifes 60 fpecies, whofe *ftem* is herbaceous, flefhy, jointed, not knotty: *fpikes* either axillary or terminal. The third fection has but two fpecies, diftinguifhed by having no *ftem*. The fourth contains one doubtful fpecies only, *P. pinnatum* of Loureiro, Cochinch. 31, whofe *leaves* are pinnate, *ftem* prickly, and *flowers* unknown, fo that it probably belongs to fome other genus.

We fhall follow Vahl's arrangement, in felecting a few examples.

P. *æquale*. Vahl n. 10. Ecl. Amer. v. 1. 4.—"Leaves elliptic-lanceolate, attenuated, fmooth; equal at the bafe; without dots beneath. Spikes ftraight."—Native of the Weft Indies. We have it from Dr. Swartz. The *branches* are polifhed, fomewhat zigzag, knotty at the joints. *Leaves* four inches long, we fhould rather call them precifely ovate, and pointed, very fmooth, with many lateral curved ribs, fpringing from the main one, and connected by fine interbranching veins. *Spikes* an inch or more in length, exactly cylindrical, obtufe, folitary, oppofite to each leaf, their *ftalks* about the length of the *footftalks*, which is ufually a quarter of an inch.

P. *aduncum*. Hooked Pepper, or Spanifh Elder. Linn. Sp. Pl. 41. Vahl n. 24. Willd. n. 17. Ait. n. 6. Jacq. Ic. Rar. t. 210.—Leaves ovate-oblong, or elliptic, pointed, rough; unequal at the bafe. Spikes hooked.—Native of the Weft Indies, as well as of the continent of South America. The *leaves* are a fpan long, rough on both fides to the touch, like a fine file, with many ftraight tranfverfe ribs. *Spikes* three inches long, remarkably incurved. *Flowers* regularly whorled. Sloane fays in his Hiftory of Jamaica, v. 1. 135, that the *root* is very famous, refembling ginger in tafte, colour, and fmell, and when frefh not inferior to it.

P. *ariftolochoides*. Lamarck Illuftr. 80. Vahl. n. 43.—Leaves heart-fhaped, acute, dotted with numerous radiating ribs. Footftalks bordered. Spikes axillary, fomewhat aggregate, from a lanceolate fheath. Gathered by Commerfon in the ifland of Mauritius. The *leaves* are the fize and fhape of *Ariftolochia Sipho*; the *ftalks* and *branches* roughifh, but we do not find them villous. *Spikes* fmall, two or more together. This plant is very near Forfter's *methyfticum*, Vahl. n. 66, and perhaps not different from it.

P. *nigrum*. Black Pepper. Linn. Sp. Pl. 40. Vahl. n. 52. Willd. n. 1. Ait. n. 1. Mill. Illuftr. t. 5. Woodv. Med. Bot. t. 187. Ger. Em. 1538.—Leaves broad-ovate, pointed, coriaceous, fmooth, with feven ribs. Joints of the ftem tumid.—Native of the Eaft Indies. Said in Hort. Kew. to have been introduced into the Englifh ftoves, in 1790, by Meffrs. Lee and Kennedy. The three central ribs, in our fpecimens, are combined at the bafe for about an inch. M. Poiret, in Lamarck's Dict. v. 5. 458, juftly remarks that J. Miller alone, in his Illuftr. of the Linn. Syft. has defcribed a *corolla*, or *calyx*, of one leaf, with three notches, in this plant. No perfon has been able to verify this reprefentation, nor is it known whence Miller procured his drawing, unlefs perhaps from his fon, a botanical artift, who vifited India. His plate has always been confidered as a valuable addition to the hiftory of a plant fo imperfectly known to botanifts, and it is pity any uncertainty fhould be attached thereto. Woodville's figure is a copy of Miller's. More than one fpecies perhaps has been confounded under *P. nigrum*, particularly the *fylveftre* of Loureiro, Lamarck, and Vahl n. 45; nor have we materials to clear up this confufion.

P. *Cubeba*. Cubebs. Linn. Suppl. 90. Vahl. n. 61. Willd. n. 3. Gærtn. t. 92. (Piper caudatum; Ger. Em. 1540. Cubeba; Woodv. Med. Bot. v. 4. 165.)—Leaves elliptic-lanceolate, pointed, fmooth, five-ribbed; contracted and unequal at the bafe; the middle ribs combined half way up. Berries on partial ftalks. Native of Sierra Leone, from whence we have fpecimens, gathered by profeffor Afzelius and his companion Borone, in leaf and fruit; fo that no further doubt can remain as to the identity of the plant. There are others, without name or mark, in the Linnæan herbarium. We know of no figure of any part except the *fruit*, as above cited. The *ftem* is round, fmooth, zig-zag, ftriated, with rather tumid joints. *Leaves* two or three inches long, and one broad, folitary at each joint, on fhort ftalks; furnifhed with three principal ribs from the bafe, and with two more, which fpring very irregularly and varioufly from the central one, towards the middle of the leaf. The bafe of the *leaves* in the Linnæan fpecimen is more dilated, and vifibly unequal, than in thofe from Sierra Leone, but we fcarcely think it indicates a fpecific difference. The *clufters* are two inches long; partial ftalks half an inch.

The fpecies of Vahl's fecond fection are ufually of humble growth, and a fhining, pellucid, fucculent habit. Such is

P. *obtufifolium*. Blunt-leaved Pepper. Linn. Sp. Pl. 42. Willd. n. 31. Vahl. n. 79. Ait. n. 13. Trew Ehret. t. 96.—Leaves obovate; riblefs beneath.—Native of the Weft Indies. The Linnæan fpecimen came from Jamaica. Vahl confounds with this the *clufiæfolium*, Jacq. Ic. Rar. t. 212, but they are kept feparate in Hort. Kew. The *ftem* is moft fpotted in *obtufifolium*; the *leaves* darker in *clufiæfolium*, with more confpicuous lateral ribs. Thefe fpecies and many others of this fection, want a thorough inveftigation, and a careful comparifon with each other, to be well underftood; neither is the whole genus fo completely fettled as could be wifhed, notwithftanding the labours of Vahl, which have not extended fufficiently to the fynonyms.

Piper, in *Gardening*, contains plants of the herbaceous, fhrubby, perennial, exotic kinds, of which the fpecies cultivated are; the black pepper (P. nigrum); the rough-leaved pepper (P. amalago); the long pepper (P. longum); the intoxicating pepper, or ava (P. methyfticum;) the netted-leaved pepper (P. reticulatum); the hooked-fpiked pepper (P. aduncum); the pellucid-leaved pepper (P. pellucidum); and the blunt-leaved pepper (P. obtufifolium).

On the firft fort Martyn obferves, that "white pepper was formerly thought to be a different fpecies from the black; but it is nothing more than the ripe berries deprived of their fkin, by fteeping them about a fortnight in water; after which they are dried in the fun. The berries falling to the ground when over-ripe, lofe their outer coat, and are fold as an inferior fort of white pepper.

Method of Culture.—All thefe plants may be increafed by feeds, procured frefh from the countries where the plants grow naturally, which fhould be fown upon a good hot-bed in the fpring; and when the plants come up and are fit to tranfplant, be each put into a feparate fmall pot filled with light frefh earth, and replunged into a hot-bed of tanners' bark, fhading them every day from the fun till they have taken frefh root, when they muft be treated in the fame way as other tender exotic plants, admitting frefh air to them daily in proportion to the warmth of the feafon, to prevent their drawing up weak; and when the nights are cold the glaffes of the hot-bed fhould be covered with mats.

They all require the conftant protection of a hot-houfe.

As the ftalks of moft of them are tender when young, they fhould not have much wet, which rots them; and when water is given it muft be with caution, not to beat down

P I P

down the plants; for when that is the caſe they ſeldom riſe again afterwards.

In ſome of the ſorts they may be raiſed from layers or cuttings.

In the after-management of the plants, they muſt be plunged into the tan-bed of the bark-ſtove in the autumn, and during the winter be ſparingly watered; they require the ſame warmth as the coffee-tree. In the ſummer a large ſhare of freſh air muſt be admitted in hot weather, and they muſt be conſtantly kept in the ſtove, as already ſuggeſted.

They afford ornament and variety in ſtove collections.

Piper *Chiapæ*, in *Botany*, a name given by ſome authors to the clove-berry-tree, or caſſia caryophyllata.

Piper, *Jamaica*. See Myrtus *Pimenta*.

Piper *Nigrorum*, *Negro pepper*. The plant called at preſent by this name is the *capſicum*, or *Guinea pepper*, a remarkable herb, bearing large pods as red as coral, of which the Cayenne butter is made in America. But this is not the plant that was anciently known by this name. Avicenna and Serapion both mention a plant, which they call *fulful alſuaden*, the Engliſh of which is, the *pepper of the black people*. But this was properly what has been ſince called the *Ethiopian pepper;* a ſort of hot ſeeds approaching to the nature of the common pepper, and containing ſeveral together in pods.

It is not eaſy, from the accounts we have left, to ſay what it is; but they have left deſcription enough of it for us to ſay what it is not, and to find that they have all been miſtaken, who have ſuppoſed it to be either the root tarſi, or the bulbus of the Arabians, which laſt was as large as a pear. See Capsicum.

Piper *Tavaſci*, the clove-berry-tree, or caſſia caryophyllata; a tree whoſe bark is uſed in medicine.

Piper, *Sand*, in *Ornithology*. See Arenaria and Tringa *Interpres*.

Piper, in *Ichthyology*, the Engliſh name of a ſpecies of *trigla*, called by the generality of authors *lyra*. See Trigla *Lyra*.

PIPERAH, in *Geograghy*, a town of Hindooſtan, in Bahar; 22 miles S.S.W. of Patna.

PIPERAPIUM, an old name of a plant found in Apuleius, and ſaid to have its name from its heat to the taſte; which was ſo offenſive to the bees, that if a piece of it were hung up in the hive, it would drive them all out.

This is a very ſtrange account: and as we meet with nothing to countenance it in any other author, there is reaſon to ſuſpect it to be an error; and there ſeems this foundation for it. The acorus root is ſaid by Dioſcorides to be the root of a plant allied to the papyrus, or paper-reed of the river Nile; and is thence called by that author *papyraceous*. Avicenna and Serapion copy this, and liken the acorus plant to the papyrus; but in all the copies of the Greek author, it is often found written ϖεπερακιον. This word *peperacion* may have been formed by Apuleius into *piperapium*, by way of amendment, and all the reſt might be occaſioned by this.

PIPERI, in *Geography*, a ſmall iſland in the Grecian archipelago; ſix miles N. of Serpho.

PIPERIDGE Tree, in *Botany*. See Berberis.

PIPERINO, in *Mineralogy*, a ſubſtance that ſeems to be a concretion of volcanic aſhes, and is ſaid to be that which covers Pompeii. Its colour, grey, or reddiſh-brown; its luſtre and tranſparency, 0; its fracture earthy, contains fragments of white marble, feldſpar, mica, garnets, ſcoriæ, gypſum, ſhorl, granite, &c.; its hardneſs, 6; ſometimes magnetic, ſometimes not.

It ſeems to differ from tufas, in containing more heterogeneities, being in fact a kind of porphyry or breccia, and being more eaſily decompoſed by expoſure to moiſture and the open air, but if preſerved from moiſture, it hardens when expoſed to the air. Kirwan.

PIPERITIS, in *Botany*, a name given by ſome authors to the momordica, or male balſam apple.

PIPERIVORA Avis, in *Ornithology*, a name given by ſome authors to the toucan, or Braſilian magpye, from its feeding on pepper.

PIPERNO, in *Geography*, a town of Italy, in the Campagna di Roma, formerly the ſee of a biſhop, but in 1225, on account of its poverty, united to Terracina. It was built out of the ruins of the ancient *Privernum*, which ſee; nine miles N.N.W. of Terracina.

PIPEROONE, a town of Hindooſtan, in Bahar; 25 miles N. of Durbungah.

PIPERRY, a town of Hindooſtan, in Candeiſh; 32 miles S.S.E. of Chuprah.

PIPILE, in *Ornithology*, a ſpecies of *Penelope;* which ſee.

PIPING, in *Sea Language*. See Call.

Piping-*Tree*, in *Geography*, a town of America, in Virginia; nine miles E. of Newcaſtle.

PIPIRI, in *Ornithology*, a name given by Buffon to the Lanius *Tyrannus;* which ſee.

PIPISTRELLUS, in *Zoology*, a ſpecies of *Veſpertilio;* which ſee.

PIPLERCHE, in *Ornithology*. See Alauda *Criſtata*.

PIPLEY, in *Geography*, a town of Hindooſtan, in Baglana; ſix miles N.W. of Bahbelgong.—Alſo, a town of Hindooſtan, in the country of Berar; 18 miles N. of Jaffierabad.—Alſo, a town of Hindooſtan, in Bengal, near the borders of Oriſſa, on a branch of the Ganges, and formerly a place of trade, having an Engliſh and Dutch factory; but the trade declined, and the factories were removed to Hoogly and Calcutta; 22 miles N.E. of Balaſore.

PIPPARAH, a town of Hindooſtan, in Oude; 42 miles N.W. of Lucknow.—Alſo, a town of Hindooſtan, in Oude; 48 miles E. of Bahraitch.

PIPRA, the *Manakin*, in *Ornithology*, a genus of birds of the order Paſſeres. The generic character is; bill ſhort, ſtrong, hard, nearly triangular at the baſe, and ſlightly incurved at the tip; the noſtrils are naked, the feet formed for walking, the tail is ſhort. Theſe birds are very ſimilar to the genus of Titmice, and are almoſt all peculiar to South America. In Gmelin there are thirty-one ſpecies enumerated; Latham mentions but twenty-five.

Species.

Rupicola; Rock Manakin. Creſt erect, edged with purple; the body is of a ſaffron colour; the tail-coverts are truncate. It inhabits the rocky parts of South America, and is the ſize of a ſmall pigeon. It is extremely ſhy, but may be tamed if taken very young; it feeds on ſmall wild fruits, and builds in the clefts of the moſt remote rocks. It lays two white eggs at a time. The female, and the male alſo when young, are brown; the lower wing-coverts are rufous and orange.

Peruviana; Peruvian Manakin. Body ſaffron-red; greater wing-coverts cinereous; quill and tail-feathers black; the coverts of the latter are not truncate. It is a native of Peru, and of the ſame ſize as the laſt.

Pareola; Blue-backed Manakin. Creſt blood-red, body black; back blue. It inhabits South America, and is four inches and a half long.

Superba; Superb Manakin. Deep black; middle feathers of the crown longiſh, and of a flame colour; beneath the wings are pale blue lunular blotches; primary quill-

featners

feathers brownish. It is larger than the Aureola, to be noticed hereafter.

Cristata; Purple Manakin. Crest pale yellow; body purple. It inhabits Brasil and New Spain, and is three inches and a half long.

Picicitli; Mexican Manakin. Cinereous; head and neck black; round the eyes is a whitish spot, which ends in a point at the breast. It is very small, and found in Mexico.

Rubetra; Yellow Manakin. Crest pale yellow; body testaceous; quill and tail-feathers blue. It is found in Brasil and Cayenne. The bill is yellow; the chin brown, and the neck is marked with a golden colour.

Torquata; Collared Manakin. Black; head scarlet; quill feathers and coverts blue. It inhabits Brasil, and is about three inches and a half long.

Miacatototl; New Spain Manakin. Black, with a few whitish feathers; belly pale; wings and tail beneath cinereous.

Punctata; Speckled Manakin. Greyish-brown, waved with dusky; top of the head and wings black, speckled with white; tail-coverts red. Found in New Holland.

Grisea; Grey Manakin. Grey, beneath yellow; hind-head crested; greater wing-coverts red; quill-feathers and tail grey-ash; the front is marked with a yellow spot.

Albifrons; White-faced Manakin. Crest white; body testaceous; back black. There is a variety with a rusty-testaceous body; crest is long and unequal. They are found in divers parts of South America.

Erythrocephala; Gold-headed Manakin. Black; head and arm-pits tawny. There is a variety of this species which is black; the head and bracelets red.

Aureola; Red and black Manakin. Black; head and breast scarlet; quill-feathers with a white spot on the fore-part. A variety has the head, lower part of the neck, breast, belly, and edges of the wings, orange; the quill-feathers have a white spot within. It inhabits Guinea. The *first* has a black bill, with legs and claws red; the *second* has them brown.

Caudata; Long-tailed Manakin. Blue; crown scarlet; wings black; two middle tail-feathers long and pointed. It inhabits South America; the sides and neck are tinged with a bright green lustre.

Leucocephala; White-headed Manakin. Black, with a white head. It is a native of Surinam, and is the size of a warbler.

Leucocilla. Dusky-black; cap white; a variety is dusky-black; cap white; bracelets red. It is found among the reedy places of South America.

Gutturalis; White-throated Manakin. Black, throat white. It is a native of the hottest parts of South America.

Serena; White-fronted Manakin. Black; front white; rump blue; belly tawny. It is a native of Guiana and Cayenne.

Manacus; Black-capped Manakin. Black, beneath white; spot on the wings and neck above white. A variety of this species is without the spot on the wings.

Minuta; Little Manakin. Grey; head black, speckled with white. It inhabits India, and is the size of a wren.

Striata; Striped-head Manakin. Beneath yellowish; upper part of the head and nape black, the feathers with a white streak lengthways; the quill-feathers are black, the third very short.

Nævia; Spotted Manakin. Brown, beneath tawny; chin and throat black; breast bifid, band on the wings, and tips of the tail-feathers white. It is about four inches long.

Leucotis; White-eared Manakin. Varied with olive and rufous, beneath rufous; belly grey; crown brown; temples and chin black; on each side the neck is a tuft of long snowy feathers. This is nearly five inches long.

Atricapilla; Black-crowned Manakin. Pale ash-colour, beneath grey-white; bill, crown, greater wing-coverts, and quill-feathers black, the latter edged with grey; the front and cheeks are of a grey-white. It is six inches long, and inhabits Guiana. It avoids the open plains, and haunts the skirts of woods in small flocks. The birds of this species are found in the neighbourhood of ant's nests, from which they are sometimes seen to spring as if stung by the insects, uttering, at the moment, a cry similar to the noise made by cracking a nut.

Papuensis; Papuan Manakin. Greenish-black, beneath whitish; breast with an oblong orange blotch; middle tail-feathers very short. It is a native of New Guinea.

Hœmorrhea; Crimson-vented Manakin. Deep black, beneath white, vent with a red spot.

Nigricollis; Black-throated Manakin. Blueish-black; throat and vent black; belly white.

Capensis; Orange-bellied Manakin. Dusky-black, beneath pale orange; edge of the quill-feathers pale, of the wings pale yellowish-orange.

Cinerea; Cinereous Manakin. Cinereous; belly whitish.

Musica; Tuneful Manakin. Black, beneath orange; the front and rump yellow; the crown and nape blue; chin and throat black. This is a native of St. Domingo, and is about four inches long. It is extremely shy, and easily eludes the vigilance of those who attempt to catch it; its note is very musical, and forms a complete octave, one note succeeding another. The bill and legs are black.

Pipra, a name given by Aristotle, and other ancient writers, to the *picus varius major*, the great spotted wood-pecker, or witwall.

PIPRAH, in *Geography*, a town of Hindoostan, in Visiapour; 13 miles S.E. of Poorunda.—Also, a town of Hindoostan, in Rohilcund; 17 miles S.E. of Budayoon.—Also, a town of Hindoostan, in Oude; 38 miles N.N.E. of Manickpour. N. lat. 26°. E. long. 82° 18′.

PIPRIAC, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Rédon; 10 miles N. of Rédon. The place contains 3150, and the canton 12,161 inhabitants, on a territory of 245 kiliometres, in 9 communes.

PIPROW, a town of Hindoostan, in the circar of Bopal; 10 miles S. of Bopaltol.

PIQUE, in *Natural History*, a name given by the Spaniards to an insect of the size of a flea, called by the Indians *tung*. It is common in the East and West Indies, and eats its way into the flesh under the nails, &c.

Pique, or *Piquemontvallier*, in *Geography*, the highest mountain among the Pyrenees.

PIQUERIA, in *Botany*, commemorates Andrew Piquerio, a Spanish physician and philosopher, whose works have often been republished at Venice and Amsterdam, and whose merits are highly celebrated by Cavanilles, the author of the name; though without any mention of his botanical pretensions, which would have been, in this case, most to the purpose.—Cavan. Ic. v. 3. 18. Willd. Sp. Pl. v. 3. 1748. Ait. Hort. Kew. v. 4. 501. – Class and order, *Syngenesia Polygamia-æqualis*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbiferæ*, Juss.

Gen. Ch. *Common calyx* simple, prismatic, of four or five converging, concave, keeled, equal scales. *Cor.* compound, discoid.

difcoid. Florets few, all fertile, uniform, crowded; tube very fhort; limb in five fpreading fegments. *Stam.* Filaments five, very fhort; anthers united into a cylinder. *Pift.* Germen turbinate, with five angles; ftyle thread-fhaped; ftigmas divaricated, tumid. *Seeds* folitary, minute, turbinate, with five angles, abrupt at the fummit. *Crown* or *down* none. *Receptacle* naked.

Eff. Ch. Receptacle naked. Calyx with four or five equal leaves, and as many florets. Seeds five-fided. Down none.

1. P. *trinervis*. Three-ribbed Piqueria. Cavan. Ic. v. 3. 19. t. 235.—Leaves ovato-lanceolate, ferrated, three-ribbed. Panicle fmooth.—Native of Mexico. Seeds were brought from Spain to England in 1798, by the marchionefs of Bute. The plant is biennial, flowering in the greenhoufe in July and Auguft. The *ftems* are herbaceous, four feet high, round, leafy, with oppofite branches, panicled and many-flowered. *Leaves* oppofite, on fhort ftalks, fmooth, like every other part of the plant. *Flowers* very fmall and numerous, white, on capillary, panicled, terminal ftalks. Leaves of the *calyx* four, obovate. *Florets* four.

2. P. *pubefcens*. Rough Piqueria.—Leaves dilated, three-lobed, cut. Panicle corymbofe, downy.—Native of Peru. A fpecimen of this, without any name or mark, was found in the herbarium of the younger Linnæus, amongft a number of Peruvian plants. Its *ftem* feems rather fhrubby, with oppofite, round, leafy *branches*, clothed with fine, fhort, denfe, rufty, rigid down. *Leaves* fan-fhaped, acute, nearly fmooth, varioufly cut, and more or lefs regularly three-lobed, an inch or more in length, on rough *ftalks* about half as long. *Panicle* terminal, corymbofe, denfe, many-flowered. *Calyx-leaves* five, narrower than in the former. *Florets* about five. In other refpects this plant anfwers to the generic character given of the former by Cavanilles. This genus ranges next to ETHULIA; fee that article.

PIQUET. See PICKET.

PIQUETTE, among the *Florifts*, a term ufed for a certain fort of carnations, which have always a white ground, and are fpotted, or, as they call it, pounced with fcarlet, red, purple, or other colours.

PIQUICA, in *Geography*, a town of Peru, in the diocefe of La Plata, on the coaft of the Pacific ocean; 85 miles S.W. of Atacames. S. lat. 27°.

PIQUITINGA, in *Ichthyology*, the name of a fmall American fifh, the ESOX *Hepfetus*, which fee. It feldom exceeds two inches in length; its mouth appears very fmall, but it can at pleafure open it to a great width; its eyes are very large and black, with a filvery iris; it has fix fins befides the tail, which is forked; its head is of a filvery white; its back olive-colour, and its belly and fides are covered with filvery fcales; the fins are all white, and the fide-lines are broad, and very bright and fhining. Marcgrave.

PIRA, in *Geography*, a town of Auftria; fix miles S.S.E. of St. Polten.

PIRA-*Aca*, in *Ichthyology*, a name by which Marcgrave and fome other authors have called the BALISTES *Sinenfis* of others.

PIRA-*Acangata*, the name of a Brafilian fifh, refembling the perch in fize and fhape. It is of a fmall fize, feldom exceeding four or five inches in length; its mouth is fmall; its tail is forked; and it has on the back only one long fin, which is fupported by rigid and prickly fpines; this it can deprefs at pleafure, and fink within a cavity made for it in the back; its fcales are of a filvery white. It is a wholefome and well-tafted fifh. Marcgrave.

PIRA-*Coaba*, the name of an American fifh of the truttaceous kind, much efteemed for the delicacy of its flavour. It grows to about twelve inches in length; its nofe is pointed, and its mouth large, but without teeth; the upper jaw is longer than the other, and hangs over it in form of a cartilaginous prominence; its eyes are very large, and its tail forked; under each of the gill-fins it has a beard made of fix white filaments, and is covered all over with filvery fcales. Marcgrave.

PIRA-*Guiba*. See ECHINEIS *Naucrates*.

PIRA-*Jurumenbeca*, the name of a Brafilian fifh, called by many the *bocca molie*. It lives in the muddy bottom of the American feas, and it is a long-bodied not flatted fifh; it grows to a vaft fize, being fometimes caught of nine, and fometimes even of ten or eleven feet long, and two feet and a half thick; it has one long fin on the back, the anterior part of which is thin and pellucid; and has a cavity on the back, into which the creature can deprefs the fin at pleafure; its tail is not forked; its fcales are all of a filvery colour and brightnefs. It is a very well-tafted fifh. Marcgrave.

PIRA-*Metara*, a name given by Marcgrave and others to a variety of the MULLUS *Surmuletus*.

PIRA-*Pebe*, the name given by Marcgrave to the TRIGLA *Volitans*; which fee.

PIRA-*Pixanga*, the name of a Brafilian fifh of the turdus or wraffe kind, and called by fome the *gatvifch*. Its ufual length is four or five inches; its mouth is confiderably large, and furnifhed with very fmall and fharp teeth; its head is fmall, but its eyes large and prominent; the pupil of a fine turquoife colour, and the iris yellow and red in various fhades; the coverings of the gills end in a triangular figure, and are terminated by a fhort fpine or prickle; its fcales are very fmall, and fo evenly arranged, and clofely laid on the flefh, that it is very fmooth to the touch; its tail is not forked, but rounded at the end; its whole body, head, tail, and fins, are of a pale yellow, variegated all over with very beautiful blood-coloured fpots; thefe are round, and of the bignefs of hemp-feed on the back and fides, and fomething larger on the belly; the fins are alfo fpotted in the fame manner, and are all marked with an edge of red. It is caught among the rocks, and about the fhores, and is a very well tafted fifh. Marcgrave.

PIRÆUS, or PYRÆUS, in *Ancient Geography*, a celebrated and capacious harbour of Athens, about 35 or 40 ftadia from the city, but joined to it by walls about five miles in length; that on the north was built by Pericles, and that on the fouth by Themiftocles. This was made the port of Athens by the latter commander, who obferving that the ancient port of Phalerum was narrow and inconvenient, conftructed the Piræus, which he made the moft capacious haven in Greece, and conceiving it inexpedient that the port fhould be made a part of the city, becaufe, as he knew that failors are generally diffolute, he was afraid their mixing with the citizens would produce a corruption of manners, he built it at a diftance, and connected it with the city by long walls. The fcite of this port was originally a village of Attica; and in order to render it fecure it was encompaffed by ftrong walls. The whole of its circuit was 60 ftadia, including the "Munychia," which was a promontory near it, and which being naturally very ftrong, was rendered ftill ftronger by artificial fortification. On the walls that joined the Piræus with the city, were erected turrets, which were afterwards converted into dwelling-houfes for the accommodation of the Athenians, whofe large city became in procefs of time too fmall for them. It was after the battle of Salamis, which happened in the firft year of the 75th olympiad, 480 years B.C., and by by which Athens was elevated to a very high degree of glory, that Themiftocles projected the fcheme of conftructing this new harbour. Accordingly in the laft year of the 75th olympiad, 477 years B.C., he explained to the citizens the plan which he had conceived for eftablifhing their power and increafing their wealth. In order the more effectually to fecure their concurrence, after ftating the advantages that would refult to them from the execution of his plan, he requefted them to appoint two perfons of rank and talents, to whom he might freely communicate the whole of his project. The affembly of the citizens appointed Ariftides and Xanthippus, to whom Themiftocles imparted, without referve, his fcheme of rendering the Piræus a fafe and capacious harbour. To thefe he demonftrated how eafily his fcheme might be accomplifhed, if his intentions were kept fecret, and at the fame time informed them how dangerous it would be for the Spartans to be apprifed of his defign. Ariftides and Xanthippus affured the people, that the project of Themiftocles was of the utmoft advantage to the ftate, and yet that it might be performed with the greateft eafe. Neverthelefs the people entertained fufpicions of fome finifter defigns, and recommended Themiftocles's application to the fenate, who having obtained their confent fent ambaffadors to Sparta, intimating how fit it would be for the Greeks to have fome great port, where a fleet might continue in fafety, to watch the defigns of the Perfians. Having thus prepared the Lacedæmonians not to take offence at their firft preparations for enlarging and eftablifhing the harbour of Piræus, Themiftocles took fuch care that every thing was finifhed, and the place in a pofture of defence, before it was well known in Sparta what the Athenians were about.

The entrance of the Piræus is narrow, and formed by two rocky points, one belonging to the promontory of Eetion and the other to that of Alcinous. Within were three docks or ftations for fhipping, Cantharos, Aphrodifium, and Zea; the firft fo called from an ancient hero, the fecond from the goddefs Venus, who had there two temples, and the third from bread-corn. In this port were alfo five porticos, which, joining together, formed one great arcade, called "Macra Stoa," or the grand portico. There were likewife two large markets or fora, one near the long portico, and one near the city. The walls were formed of hewn fquare ftones, and united without cement, merely by lead and iron, which ferved to hold together the exterior ranges or facings. They were fo wide that loaded carts might pafs upon it in different directions, and their height was about 40 cubits. Thefe long walls were repaired by Conon, deftroyed almoft wholly by Lyfander, the Lacedæmonian, and partly reconftructed by Conon, and perfected by Callicrates, during the government of Pericles.

The Piræus, as long as Athens flourifhed, became the emporium of all Greece. The architect was Hippodamus celebrated for the conftruction of other buildings.

At the Piræus were a theatre, a temple, or chapel, in which were two ftatues, one of Jupiter with a fceptre in his hand, and one of Minerva with a pike, and others of Venus, &c. The cavities and windings of the Munychia, both natural and artificial, were filled with houfes; and the whole fettlement comprehending Phalerum and the ports of the Piræus, with the arfenals, the ftore-houfes, the famous armoury of which Philo was the architect, and the fheds for 300, and afterwards 400, triremes, refembled the city of Rhodes, which had been planned by the fame Hippodamus. The ports, on the commencement of the Peloponnefian war, were fecured with chains, centinels were ftationed, and the Piræus was carefully guarded.

It was with great difficulty that the Piræus was reduced by Sylla, who demolifhed the walls, and fet fire to the armoury and arfenals. In the civil war it was in a defencelefs condition. Calenus, lieutenant to Cæfar, feized it, invefted Athens, and ravaged the territory. Strabo, who lived under the emperors Auguftus and Tiberius, obferves, that by many wars the long walls had been deftroyed, together with the fortrefs of Munychia, and that the Piræus had been contracted into a fmall fettlement by the ports and the temple of Jupiter the Saviour. This fabric was then adorned on the infide with pictures, the works of illuftrious artifts, and on the outfide with ftatues. In the fecond century, befides houfes for triremes, the temples of Jupiter and Minerva remained, with their images in brafs, and a temple of Venus, a portico and the tomb of Themiftocles, whofe bones were conveyed hither by his friends from Magnefia.

The port of the Piræus has been named "Porto Lione," from its marble lion, and alfo "Porto Draco." The lion has been defcribed as a piece of admirable fculpture, ten feet high, and repofing on its hinder parts. Near Athens, in the way to Eleufis, was another, in a couchant pofture, probably the companion of the former. Both thefe were removed to Venice by the famous general Morofini, and placed before the arfenal. At the mouth of the port are two ruined piers. It is frequented by a few veffels, which are, for the moft part, fmall craft. The buildings are a mean cuftom-houfe, with a few fheds, and by the fhore, on the eaft fide, a warehoufe belonging to the French and a Greek monaftery dedicated to St. Spiridion. On the oppofite fide is a rocky ridge, on which are remains of the ancient wall and of a gateway towards Athens. By the water-edge are veftiges of building; and between the cuftom-houfe and the city on the right hand of the road are traces of a fmall theatre on the fide of the hill of Munychia.

PIRAGUIRI, in *Geography*, a town of Brafil, in the government of Para, on the Xingi; 85 miles S.W. of Curupa.

PIRANHA, in *Ichthyology*, a name given to the American fifh, more commonly known by the name piraya.

PIRANO, in *Geography*, a fea-port town of Iftria, fituated partly on an eminence, and partly on an ifthmus; nine miles S.W. of Capo d'Iftria. N. lat. 45° 37′. E. long. 13° 36′.

PIRAQUIBA, or IPIRAQUIBA, in *Ichthyology*, a name originally Brafilian, by which fome authors exprefs the remora, or fucking-fifh.

PIRATE, PYRATE, *Pirata*, *Rover*, a perfon, or veffel, that robs on the high feas, or makes defcents on the coafts, without the permiffion or authority of any prince or ftate.

The colours ufually difplayed by pirates are faid to be a black field, with a death's head, a battle-axe, and an hour-glafs.

By the ancient common law, piracy, if committed by a fubject, was held to be a fpecies of treafon, and by an alien to be felony only; but now, fince the ftatute of treafons, 25 Edw. III. cap. 2. it is held to be only felony in a fubject. Formerly it was only cognizable by the admiralty courts, which proceed by the rules of the civil law; but the ftatute 28 Hen. VIII. cap. 15. eftablifhed a new jurifdiction for this purpofe, which proceeds according to the courfe of the common law. The offence of piracy, by common law, confifts in committing thofe acts of robbery and depredation upon the high feas, which, if committed upon land, would have amounted to felony. But, by by ſtatute, ſome other offences are made piracy alſo; as by 11 & 12 W. III. cap. 7. if any natural born ſubject commits any act of hoſtility upon the high ſeas, againſt others of his majeſty's ſubjects, under colour of a commiſſion from any foreign power, this, which would be only an act of war in an alien, ſhall be conſtrued piracy in a ſubject. And farther, any commander, or other ſea-faring perſon, betraying his truſt, and running away with any ſhip, boat, ordnance, ammunition, or goods, or yielding them up voluntarily to a pirate, or conſpiring to do theſe acts; or any perſon confining the commander of a veſſel, to hinder him from fighting in defence of his ſhip, or to cauſe a revolt on board, ſhall, for each of theſe offences, be adjudged a pirate, felon, and robber, and ſhall ſuffer death, whether he be a principal or acceſſory. By 8 Geo. I. cap. 24. the trading with known pirates, or furniſhing them with ſtores or ammunition, or fitting out any veſſel for that purpoſe, or in anywiſe conſulting, combining, confederating, or correſponding with them; or the forcibly boarding any merchant veſſel, though without ſeizing or carrying her off, and deſtroying or throwing any of the goods overboard, ſhall be deemed piracy; and all acceſſories to piracy are declared to be principal pirates and felons, without benefit of clergy. Commanders or ſeamen wounded, and the widows of ſuch as are ſlain, in any piratical engagement, ſhall be entitled to a bounty, to be divided among them, not exceeding one-fiftieth part of the value of the cargo on board; and ſuch wounded ſeamen ſhall be entitled to the penſion of Greenwich hoſpital. And if the commander ſhall behave cowardly, by not defending the ſhip, if ſhe carries guns or arms, or ſhall diſcharge the mariners for fighting, ſo that the ſhip falls into the hands of pirates, ſuch commander ſhall forfeit all his wages, and ſuffer ſix months' impriſonment.

In different parts pirates are differently denominated; as in the Weſt Indies, *buccaneers*, *free-booters*, &c. In the Mediterranean, *corſairs*, &c.

Alexander, reproaching a pirate with his condition, was anſwered, "If I am a pirate, it is becauſe I have only a ſingle veſſel; had I a fleet, I ſhould be a mighty conqueror."

Pirate was alſo anciently uſed for the perſon to whoſe care the mole, or pier of a haven, which, in Latin, was called *pira*, was entruſted.

Pirate was ſometimes too, according to Spelman, uſed for a ſea-captain, or ſoldier. Aſſer, in the life of king Alfred, tells us, "juſſit naves longas fabricari, impoſitiſque piratis in illis vias maris cuſtodiendas commiſit."

PIRATIAPIA, in *Ichthyology*, the name of a Braſilian fiſh, approaching to the nature of the turdus or wraſſe. Its body is oblong, not flatted, and very thick; it is a large fiſh, and ſometimes grows even to fifty pounds weight. It is a very delicate and valuable fiſh. Marcgrave.

PIRATIA-PUA, the name of an American ſea-fiſh, which grows to a very large ſize, and, while young, is eaten and accounted a delicacy; but when full grown, is too coarſe, rank, and ſtrong: it has ſix fins beſides the tail, which is made of a very large fin, of a ſomewhat ſquare figure, and is not at all forked: it is all over of a duſky orange colour, but more obſcurely ſo on the back than elſewhere; and its ſides are variegated with grey ſpots, ſo diſpoſed as to repreſent a ſort of net-work. Piſo.

PIRAUGY, in *Geography*, a river of Brazil, S.S.E. of Rio Grande and Point Negro.

PIRAUMBU, in *Ichthyology*, the name of a Braſilian fiſh, ſomewhat approaching to the nature of the turdus, and called by the Portugueſe *chayquarona*. It is of the figure of the carp, and its uſual length is ſix or ſeven inches, and its breadth in the broadeſt part about three inches, but gradually diminiſhing to the tail. It is caught among the rocks, and near ſhores, and is a well taſted fiſh. Marcgrave.

PIRAY, in *Geography*, a river which runs into the Paraguay.

PIRAYA, a town of Paraguay; 20 miles S.E. of Aſſumption.

Piraya, in *Ichthyology*, the name of a fiſh caught in the American rivers. There are two kinds of it: the one growing to a foot long, and very broad in proportion; this loves the muddy bottoms of rivers; the other is much of the ſame ſize, but has two fins on its back, whereas the other has but one; this loves the ſandy bottoms of rivers. There is alſo a ſmaller ſpecies of this: all three are eatable fiſh.

PIRAZZETA, in *Geography*, a town of Naples, in Baſilicata; 14 miles N.E. of Turſi.

PIRDE, a river of Pruſſia, which runs into the Memel, four miles W. of Tilſit.

PIRETIBBI, a lake of Canada, 240 miles N. of Quebec. N. lat. 51°. E. long. 69° 40′.

PIRGIA, a town of Aſiatic Turkey, in Caramania; 112 miles S.W. of Cogni.

PIRGO, a town of Albania, at the mouth of the river Polonia; 20 miles N. of Valona.

PIRHALA, a town of Hindooſtan, in Lahore; 108 miles N.W. of Lahore. N. lat. 32° 36′. E. long. 71° 56′.

PIRI, a province of Africa, in the N. part of the kingdom of Loango.

PIRIATIN, a town of Ruſſia, in the government of Kiev; 68 miles E.S.E. of Kiev. N. lat. 51° 18′. E. long. 32° 42′.

PIRIG, a town on the S. coaſt of the iſland of Luçon. N. lat. 13° 39′. E. long. 122° 24′.

PIRIGARA, in *Botany*, Aubl. Guian. t. 192, 193. See Gustavia.

PIRIN's Island, in *Geography*, an iſland near the coaſt of Africa, in the mouth of the river Olibato; eaſtward of cape Lopez Gonſalvo, about five miles in circumference.

PIRIOUTI, a town of Thibet; 60 miles E. of Panctou.

PIRIPEA, in *Botany*, an unexplained, probably barbarous, name. Aubl. Guian. v. 2. 627. Juſſ. 100.—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Pediculares*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, its orifice in five unequal acute ſegments. *Cor.* of one petal, ſalver-ſhaped; tube cylindrical, curved, twice the length of the calyx; limb ſpreading, in five deep, unequal, obovate ſegments; mouth cloſed with oblong glands. *Stam.* Filaments four, thread-ſhaped, inſerted into the middle of the tube, two of them longer than the reſt, all encloſed within the tube; anthers erect, oblong, of two cells. *Piſt.* Germen ſuperior, oblong, quadrangular; ſtyle ſhort; ſtigma ſwelling, acute. *Peric.* Capſule oblong, compreſſed, of two cells, and two valves. *Seeds* numerous, minute, inſerted into the partition.

Eſſ. Ch. Calyx tubular, with five unequal teeth. Corolla ſalver-ſhaped, curved; limb in five obovate, unequal ſegments; mouth cloſed with glands. Capſule of two cells. Seeds numerous, minute.

1. P. *paluſtris*. Aubl. Guian. t. 253.—Native of the meadows of Courou in Guiana, flowering and ripening fruit in September.—*Root* ſmall, fibrous, apparently annual. *Stem* a foot high, erect, ſlender, leafy, ſtriated, ſomewhat branched. *Leaves* ſcattered, ſeſſile, linear, acute, very narrow, channelled, finely toothed, ſmooth. *Flowers* in looſe, terminal, ſimple *ſpikes*. *Bracteas* three, fringed, at the baſe of

of each flower. *Flowers* hardly an inch long, purplifh; the glands at the mouth white. A pretty delicate plant, thought by Juffieu to conftitute a diftinct genus, akin to *Erinus, Buchnera, Manulea, Bartfia*, &c. We have feen no fpecimen. Swartz cites it as a fynonym to his *Buchnera elongata.* See Buchnera.

PIRIQUETA, Aubl. Guian. t. 117. See Turnera.

PIRIT, in *Ornithology*, a name given by the people of the Philippine iflands to a peculiar fpecies of fparrow, which is very common with them. It is much fmaller than our common fparrow, and feeds only on the feeds of the canary-grafs, which is very commonly wild there.

PIRITU, in *Geography*, a fmall ifland in the Caribbean fea, near the coaft of South America. N. lat. 10° 10'. W. long. 65° 26'.

PIRITZ, a town of Hinder Pomerania, which was the firft town of the country that embraced Chriftianity, and alfo the doctrines of Luther; 32 miles N. of Cuftrin. N. lat. 53° 13'. E. long. 15° 4'.

PIRLIPO, a town of European Turkey, in Macedonia; 20 miles N.N.E. of Toli.

PIRMAKAN, a town of Bengal; 15 miles S.W. of Purneah.

PIRMASENS, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the diftrict of Deux-Ponts; 12 miles S.E. of Deux-Ponts. The place contains 3205, and the canton 8147 inhabitants, in 21 communes.

PIRNA, a town of Saxony, in the margraviate of Meiffen, advantageoufly fituated on the Elbe for commerce; 11 miles S.E. of Drefden. N. lat. 50° 58'. E. long. 13° 56'.

PIRNITZ, or Botnitz, a town of Moravia, in the circle of Iglau; 10 miles S.E. of Iglau.

PIROGUIS, a name given by the Americans to their war-boats, which were a fort of canoes, fo large as to carry 40 or 50 men.

PIROM, or Tuicce, an ifland in the Red fea. N. lat. 15°. E. long. 42° 40'.

PIROMALLI, Paul, in *Biography*, an Italian Dominican, who flourifhed in the 16th century, and whofe labours have greatly contributed towards the promotion of Oriental literature, was a native of Calabria. He was fent as a miffionary into the Eaft, and was faid to have converted great numbers of the Eutychians to the Catholic faith. From Armenia he paffed into Georgia and Perfia, and upon his return into Italy by fea, he was taken and carried captive to Tunis. Being ranfomed, he went to Rome, where he gave an account of his miffion, and received marks of favour from pope Urban VIII. By this pontiff he was fent into Poland, with the character of papal nuncio, and is faid to have been very fuccefsful in reftoring union and harmony among the fects in that country. The fame pope employed him in revifing the Armenian verfion of the bible; and afterwards fent him a fecond time into the Eaft, where, in 1655, he was promoted to the bifhopric of Nackfivan, in Armenia. Over this fee he prefided nine years, and then returned to Italy, where he was nominated bifhop of Bifignano, in Calabria. Here he died in 1667. He was author of a "Latin and Perfian Dictionary;" "An Armenian and Latin Dictionary;" "A Grammar of the Armenian Tongue;" and fome treatifes in controverfial divinity.

PIRON, Alexis, a poet and man of wit, was born at Dijon in 1689. He paffed the firft twenty-five years of his life in obfcurity, remote from decent company, and devoted very much to low pleafures. A licentious ode, of which he was the author, obliged him to quit Paris, where, for fome years, he had fupported himfelf by the mechanical labours of his pen as a copying clerk. His firft literary efforts were as a writer for the comic opera, in which inferior ftation he difplayed talents that recommended him to the directors of the Theatre François. His firft effort, entitled "Les Fils ingrats," afterwards changed into "L'Ecole des Pères," was not at all fuccefsful. He next tried his powers in tragedy, and produced his "Callifthenes," and his "Cortes," neither of which has kept a place on the ftage, though containing parts ftrongly written. His "Guftave" was more fuccefsful, though critics thought it too much overcharged with bufinefs; at length, in 1738, he prefented his comedy of "La Metromanie," which raifed him to the height of reputation. He alfo wrote "Les Courfes de Tempe," an ingenious paftoral; feveral odes, poems, tales, and epigrams. In this laft kind of compofition he was particularly happy, as might be expected, confidering that he was the moft famous for repartees and bon mots of any of the Parifian wits. Of thefe feveral are given in the General Biography. He frequently made cauftic remarks upon the French Academy, and afterwards exerted himfelf to obtain admiffion into it, but was excluded by means of the abbé d'Olivet, who revived the memory of his juvenile ode, for which officioufnefs he was recompenfed by a fevere epigram. Piron never forgave the Academy for their rejection of him, and compofed the following epitaph:

> "Ci git Piron, qui ne fut rien,
> Pas même academicien."

He died at the advanced age of 83, having been long regarded as a very eftimable character. His works were publifhed collectively in feven volumes.

PIROS, in *Geography*, a jurifdiction of Peru, on the fides of the Maragnon; 160 miles N.N.E. of Lima.

PIROT, a town of European Turkey, in Bulgaria; 40 miles N.W. of Sophia.

PIROTE, a town of Hindooftan, in Malwa; 21 miles N.W. of Chanderee.

PIROUETTE, or Pyrouet, in the *Manege*, a turn or circumvolution which a horfe makes, without changing his ground; his haunches remaining firm in the centre, and his fhoulders furnifhing and defcribing the circle. In this action the inner hind leg muft not be lifted from the ground, but turned round in the fame place, like a pivot: while the other three legs and the body of the horfe turn and wheel round it at the fame time.

The word is French, and literally fignifies a whirligig.

Pirouettes are either of *one tread*, or *pifte*, or of *two*. The firft is an entire fhort turn, which the horfe makes upon one tread, and, almoft, in one time; in fuch a manner as that his head comes to the place where his tail was, without putting out his haunches. In the pirouette of *two treads*, or *piftes*, he takes a fmall compafs of ground, almoft his length, and marks both with the fore part and the hind.

PIRRAWARTH, in *Geography*, a town of Auftria; 14 miles N.N.E. of Vienna.

PIRUZABAD, a town of Perfia, in Mecran; 30 miles S.S.E. of Kieh.

PISA, in *Ancient Geography*, a town of the Peloponnefus, in that part of the Elide called Triphylia, N. of Olympia, and, according to Herodotus, 1485 ftadia diftant from Athens. It was fituated on the right of the river Alpheus, and even after its deftruction the inhabitants of this diftrict bore the name of Pifantins; and here was alfo a fountain called "Pifa." The inhabitants of this town, founded, as it is faid, by one of the grandfons of Eolus, were for a long time

time the moft powerful people of the Elide. Paufanias fays, that vines covered the fcite of Pifa.

Pisa, in *Geography*, a city of Etruria, and capital of a territory, ftands in a fertile plain, bounded by the neighbouring Apennines on the N., and on the S. open to the Tyrrhenian fea. If we may rely on the authority of Strabo, we may trace the origin of Pifa to the period that followed the Trojan war, and thus connect its hiftory with the fate of the Grecian chiefs, and particularly with the wanderings of the venerable Neftor. At all events the

" Alpheæ ab origine Pifæ
Urbs Etrufca folo,"

enjoys the double glory of being one of the moft ancient cities of Etruria, and of deriving its name and its origin from the Olympic Pifa, on the banks of the Alpheus. Although this city was always confiderable, as forming one of the Etrufcan tribes, or afterwards honoured with a Roman colony, A. U. C. 474; yet it did not arrive at the zenith of its fame till the records of ancient times were clofed, and the genius of Rome and liberty feemed for ever buried under the ruins and barbarifm of the middle ages. At that period, apparently fo unpropitious, the flame burft forth, and again kindled the flumbering fpirit of Italian freedom. Pifa was not the laft that roufed itfelf to activity; it afferted its independence at an early period, and in the 10th century blazed forth in all the glory of a mighty and victorious republic. Its numerous fleets rode triumphant on the Mediterranean; and Corfica and Sardinia, the Saracens on the coaft of Africa, and the infidel fovereign of Carthage, bowed beneath its power. Captive kings appeared before its fenate; the Franks in Paleftine and in Egypt owed their fafety to its prowefs, and Naples and Palermo faw its flags unfurled on their towers. Pontiffs and emperors courted its alliance, and acknowledged its effective fervices, and the glory of Pifa, twenty centuries after its foundation, eclipfed the fame of its Grecian parent, and indeed rivalled the achievements of Sparta herfelf, and of all the cities of Peloponnefus united. During this era of glory, commerce, as well as conqueft, introduced opulence and fplendour into the city; its walls were extended and ftrengthened; its ftreets widened and adorned with palaces, and its churches rebuilt in a ftyle of magnificence, that even now aftonifhes the traveller, and attefts the former fortunes of Pifa. A population of 150,000 inhabitants filled its vaft precincts with life and animation, and fpread fertility and riches over its whole territory. Such was its ftate during the 11th, 12th, and great part of the 13th centuries, after which the ufurpation of domeftic tyrants firft, and next the victories of the Genoefe, broke the fpirit of its citizens. Then the treachery of its princes, with the interference and deceitful politics of France, undermined its freedom, and at length the intrigues of the Medici completed its ruin, and enflaved it to its rival Florence, about the year 1228. While the neighbouring Lucca, not fo glorious but more fortunate than Pifa, ftills retains its opulence and its population. The latter, enflaved and impoverifhed, can count only 15,000 inhabitants within the whole circumference of her walls:—a number which, in the days of her profperity, would have been infufficient to man one-half of her gallies, or guard her ramparts during the watches of the night.

Pifa covers an inclofure of near feven miles in circumference; the river divides it into two, nearly equal, parts; the quays on both fides are wide, lined with edifices in general ftately and handfome, and united by three bridges, the middle one of which is of marble. The ftreets are wide, particularly well paved with raifed flags for foot paffengers, and the houfes are lofty, and of good appearance. Here are feveral palaces, not deficient either in ftyle or magnificence. Among its churches, there is a fingular edifice on the banks of the Arno, called " Santa Maria della Spina," fuppofed to have been built A. D. 1230, and repaired A. D. 1300. fo called from part of our Saviour's crown of thorns faid to be preferved there, fquare, low, and of a grotefque and whimfical, rather than beautiful appearance. It is cafed with black and white marble. This building is a fpecimen of that fpecies of architecture which the Italians call " Gotico Morefco," introduced into Italy in the 11th century, and, as its name feems to import, probably borrowed from the Eaft by the merchants of the commercial republics. We fhall here obferve, that there are in Italy two fpecies of Gothic, the " Gotico Morefco," and the " Gotico Tedefco;" the former may have been imported from the Eaft; the latter feems, as its name implies, to have been borrowed from the Germans. It is thought to be an improvement of the former.

The fineft group of buildings of the above defcription, perhaps, in the world, is that which Pifa prefents to the contemplation of the traveller in her cathedral, and its attendant edifices, the baptiftry, the belfry, and the cemetery. The cathedral is the grandeft, as it is the moft ancient; it was begun in the middle, and finifhed before the end of the 11th century. We fhall reftrict ourfelves to a defcription of the campanile or belfry, which is the celebrated leaning tower of Pifa. It ftands at the end of the cathedral, oppofite to the baptiftry, and confifts of eight ftories, formed of arches fupported by pillars, and divided by cornices. The elevation of the whole is about 180 feet. The form and proportion of this tower are graceful, and its materials, being of the fineft marble, add to its beauty; but its grand diftinction, which alone gives it fo much celebrity, is a defect which difparages the work, though it may enhance the fkill of the architect, and by its novelty forcibly arreft the attention; we allude to its inclination, which exceeds fourteen feet from the perpendicular. Many afcribe this architectural phenomenon to defign, and this is now the generally received opinion. The quantity of marble contained in the four immenfe edifices above-mentioned, and the number of pillars employed in their decoration, are truly aftonifhing. It does not appear that they belonged to any edifices in this city or its vicinity. They may have been imported by the Pifan gallies in their triumphant returns from Majorca, Sardinia, Corfica, Carthage, Sicily, and Naples, and may perhaps be confidered rather as monuments of the victories of this once powerful republic, than as remains of its municipal magnificence under the Romans. Although the ftyle of this group of edifices has been called Gothic, it is, in fact, a compofite ftyle formed of Roman orders, corrupted and intermingled with Saracenic decorations. Pifa has feveral other churches, befides the cathedral, that are magnificent and much admired. Its baths are about four miles from the city, and fpring up at the foot of " Monte St. Giuliano;" they were frequented anciently, perhaps, more than at prefent. The remains of an ancient aqueduct may be feen at a little diftance, but they are eclipfed by a modern one of 1000 arches, erected originally in order to fupply Pifa, and now carried on to Leghorn. The univerfity of Pifa was one of the nurferies of reviving literature, and under the aufpices of republican liberty, rivalled the moft celebrated academies in Italy, when they all teemed with genius and fcience. Upon the fubjugation of Pifa to the Florentines, it funk into infignificance; but it was afterwards reftored by Lorenzo de Medici: it again declined, and was reftored by the

the grand duke Cofmo I. Since that period it has continued the feat of many eminent profeffors, though it has never regained the number of its ftudents, or all its ancient celebrity. It has more than forty public profeffors, who are refident, and men of high reputation in their refpective departments. It is well furnifhed with all the apparatus of an academy;—colleges, libraries, an obfervatory, with all the aftronomical inftruments in great perfection, and an extenfive, well-ordered botanical garden. Pifa is, indeed, the feat of Tufcan education, and frequented by the fubjects of the Florentine government.

Pifa is only four miles from the fea; its port was anciently at the mouth of the Arno, and a place of fome fame and refort. It thus gave its name to a bay which extended from the promontory of Populonia, now Piombino, to that of Luna or of Venus, Porto de Venere, and was called the "Sinus Pifanus." According to Strabo, the Aufar flowed into the Arno at Pifa, though it now falls into the fea at the diftance of at leaft ten miles from it. Pifa and Leghorn are connected by a canal, 16 Italian miles in length; 42 miles W. of Florence. N. lat. 43° 42′. E. long. 10° 15′.

PISAN, IKAN, in *Ichthyology*. See CENTRISCUS *Scutatus*.

PISANG, in *Geography*. See PULO *Pifang*.

PISANIA, called alfo *Kuttijar Factory*, a town of Africa, in the kingdom of Yani, fituated on the banks of the river Gambia, about 200 miles from its mouth, where the Englifh have eftablifhed a factory. N. lat. 13° 35′. W. long. 13° 28′. This was the outfet of Mr. Park's journey for difcoveries in Africa, under the direction of the African Affociation, and the refidence of Dr. Laidley, who deferves mention on account of his kind and hofpitable treatment of the adventurous traveller, whom he received into his houfe, and attended for many weeks during a ferious illnefs; and whom he furnifhed with every neceffary for his journey, when he was difappointed of the goods requifite for his expences, taking bills upon the Affociation for the amount. From Pifania, Mr. Park proceeded eaftward to Medina, the capital of Wolli, and thence to the E.N.E. through the countries of Bondou, Kajaaga, and Kaffon, the two latter of which are feparated by the river Senegal. In his way, he took obfervations of latitude at Kolor (N. lat. 13° 49′), Koorkoorany (13° 53′), and Joag (14° 25′. W. long. 9° 37′), on this fide the river. From Joag he proceeded to Kooniakarry (14° 34′), and from Kooniakarry by Kanjee (14° 10′), both in the country of Kaffon, and Feffurah (14° 5′) in Kaarta, to Jarra (15° 5′, long. 7° 13′), in the country of Ludamar. Here he was plundered of his fextant, which accident of courfe put an end to his obfervations of latitude; and thus, unfortunately, left the remaining half (very nearly) of his geography in a ftate of uncertainty as to parallel. Mr. Park purfued his journey from Jarra by Waffiboo (14° 49′, and 95 geographical miles E. of Jarra), Diggani (lat. 14° 17′, and 266.1 geographical miles E. of Jarra), to Sego, the capital town of Bambara (lat. 14° 10′ 30″, and long. 2° 26′ W. of Greenwich.) Having at length reached the banks of the long fought for river Niger (or Joliba), near which the city of Tombuctoo ftands, Mr. Park proceeded along it feveral days' journey towards this city, on a courfe, which places Silla, the extreme point of his expedition, in lat. 14° 48′, and long. by reckoning corrected 1° 24′ W. of Greenwich. Here then terminates his journey eaftward, at a point fomewhat more than 16° E. of Cape Verd, and precifely in the fame parallel. Jinné, a large town, lies two fhort journies below Silla and Tombuctoo, twelve ftill lower down; and it would appear that all the journies were conceived to be fhort, as Mr. Park allows only 200 geographical miles for the aggregate of the fourteen journies of the caravan. (See TOMBUCTOO.) For other particulars we refer to Proceedings of the Affociation for promoting the Difcovery of the Interior Parts of Africa; containing an abftract of Mr. Park's Account of his Travels and Difcoveries, abridged from his own Minutes, by Bryan Edwards, efq.—Alfo, Geographical Illuftrations of Mr. Park's journey, and of North Africa at large, by Major Rennell, 1798.

PISAQUA, a town of Peru, in the diocefe of Arequipa, on the coaft; 40 miles S. of Arica.

PISATELLO, a river of Italy, which rifes in the department of the Rubicon or Rouagna, and being joined by two other ftreams, runs into the Adriatic, between Rimini and Cervia. See RUBICON.

PISCA PIGNATARA, a town of Naples, in the county of Molife; 15 miles N.W. of Molife.

PISCADORE ISLANDS, a clufter of iflands in the North Pacific ocean. N. lat. 11° to 11° 20′. W. long. 192° 30′ to 193°.

PISCADORES, or FISHERS, two huge rocks on the coaft of Peru, near the broken gap between Attico and Ocona. S. lat. 16° 48′.

PISCADORES. See PONG-HU.

PISCADORES, fix rocks near the coaft of Peru; 5 leagues N.N.W. of Callao. S. lat. 12° 14′.

PISCARY, PISCARA, in our *Ancient Statutes*, the liberty of fifhing in another man's waters.

This differs from a free fifhery, which is an exclufive right: in this laft the man has a property in the fifh before they are caught; in a common of pifcary, not till afterwards.

PISCATAQUA, or PASCATAQUA, in *Geography*, the only large river whofe courfe is in New Hampfhire, rifing in a pond in the N.E. corner of the town of Wakefield, and purfuing a general S.S.E. courfe of about 40 miles to the fea. It divides New Hampfhire from York county, Maine, and is called Salmon Fall river from its head to the lower Falls at Berwick, where it affumes the name of Newichawannock, which it bears till it meets with Cocheco river, which comes from Dover, when both run together in one channel to Hilton's Point, where the weftern branch meets it; from this junction to the fea the river is fo rapid, that it never freezes. At the lower falls in the feveral branches of the river are landing places, whence lumber and other country produce are tranfplanted, and veffels and boats from below difcharge their lading. This river, by its form, and the fituation of its branches, is very favourable to the purpofes of navigation and commerce. A light-houfe ftands at the entrance of Pifcataqua harbour, in N. lat. 43° 41′, and long. 70° 41′.

PISCATAWAY, a townfhip of New Jerfey, in Middlefex county, on Rariton river, fix miles from its mouth. In 1810 it had 2475 inhabitants; three miles and a half N.E. of New Brunfwick.—Alfo, a fmall poft-town of Prince George's county, Maryland, on the creek of its name which runs W. into Patowmac river, oppofite to mount Vernon in Virginia, and 14 miles S. of Wafhington. The town is 16 miles S.W. of Upper Marlborough.

PISCES, in *Aftronomy*, the twelfth fign, or conftellation of the zodiac.

The ftars in Pifces, in Ptolemy's Catalogue, are 38; in Tycho's, 36; in Hevelius's, 39; in the Britannic Catalogue, 113. See CONSTELLATION.

PISCES, in *Natural Hiftory*, is the name of the fourth of the claffes into which Linnæus has diftributed the animal kingdom;

kingdom; and the ſcience treating of the orders, genera, ſpecies, &c. of this claſs, is denominated *Ichthyology*. From this word we referred to the preſent article, meaning to give a very brief ſketch of the ſcience, ſo much having been already ſaid of the ſtructure, the anatomy, and functions of fiſhes under the article FISH, to which we refer our readers for abundant of intereſting information on the ſubject.

The element in which fiſhes live prevents us from following their motions with exactneſs, from coming to any very accurate knowledge of their habits and inſtincts, and from noting with fidelity their ſpecific differences. Their colours, which ſometimes are very brilliant, frequently vary, with the accidental circumſtances of age, ſex, climate, ſeaſon, &c., and often vaniſh by expoſure to air, or with the principle of life. Hence the natural hiſtory of fiſhes has ever been involved in greater obſcurity than that of land animals, which are more readily ſubjected to the inveſtigation of the learned and curious. Hence the earlier writers on this ſubject, as Ariſtotle, Pliny, and Ælian, have mingled as much fable as truth in their accounts, ſo that they afford few facts that can be depended upon in a ſcientific point of view. The claſſical reader may, however, derive entertainment and ſome inſtruction from a peruſal of their books, with the comments of the learned upon them. Athenæus alſo diſcourſes of fiſhes in the ſeventh book of his Deipnoſophiſtæ, as does Oppian in his Halieuticon, a Greek poet, who flouriſhed under the reign of Caracalla. (See OPPIAN.) Auſonius, a native of Bourdeaux, in the fourth century, in his poem on the river Moſelle, has not paſſed its inhabitants unnoticed. In the dark and middle ages, no writer of note appeared in this department of natural hiſtory. The firſt perſon who laid the foundation of ichthyological arrangement was Pierre Belon, a French phyſician, who flouriſhed in the fixteenth century, and who is known by his travels in Judea, Greece, and Arabia, as well as by his writings in natural hiſtory. Some of his diviſions are deduced from natural reſemblances, but others are more fanciful. Belon was an induſtrious and acute obſerver, and will be deſervedly held in eſtimation when it is conſidered how few the reſources were of which he could avail himſelf. (See BELON.) His hiſtory of fiſhes appeared in 1551; that of his countryman Rondelet was publiſhed three years afterwards, and exhibited more accurate deſcriptions, and better executed figures, with many excellent remarks, the reſult of his own obſervation. He had the merit of exciting a general taſte for the ſtudy of ichthyology, and was rapidly followed by Salviani, Boſſueti, Conrad Geſner, Piſon, &c.

Aldrovandus, in 1605, who publiſhed a large compilation of Natural Hiſtory, diſtributed the fiſhes according to the nature of their reſidence: thus he treats, in his *firſt* book, of thoſe that frequent rocks; in the *ſecond*, of thoſe that live cloſe to the ſhores, &c. The labours of this naturaliſt, and of others in the ſame department, were eclipſed by thoſe of Willoughby, whoſe work, entitled "De Hiſtoria Piſcium," was printed at Oxford in 1686, and unfolded many new and accurate notions relative to the anatomy and phyſiology of fiſhes. His arrangement may be conſidered as an improved modification of that of Belon. Ray publiſhed, in 1707, his "Synopſis Methodica Piſcium," which may be regarded as an abridged and corrected view of Willoughby's larger work, and as indicating, rather than fixing, a ſeries of genera. This valuable deſcriptive catalogue continued to be appealed to as a ſtandard, till Artedi and Linnæus effected important changes in the ſcience of ichthyology. The former of theſe died before he could mature the plan on which he was engaged, and Linnæus, his friend and coadjutor, put the finiſhing hand to his papers, and then publiſhed them in two vols. 8vo. under the titles of "Bibliotheca Ichthyologica," and "Philoſophia Ichthyologica," which in 1792 were republiſhed in four vols. On this account we may aſcribe to Artedi the merit of having firſt traced the outlines of that claſſification of fiſhes which is now generally received among the ſtudious and learned in Europe. He firſt inſtituted the orders and genera, and defined the characters on which theſe diviſions are founded. Independently of the cetaceous tribes, which are now claſſed with the Mammalia, the method of Artedi conſiſted of four great diviſions, *viz.* 1. The *Malacopterygian*, which denoted thoſe fiſhes which have ſoft fins, or fins with bony rays, but without ſpines: this order included 21 genera. 2. The *Acanthopterygian*, or thoſe with ſpiny fins, containing 16 genera. 3. The *Branchioſtegous*, which correſponds to the *amphibia nantes* of Linnæus, which want the operculum, or branchioſtegous membrane; and 4. The *Chondropterygian*, which anſwers to that part of the amphibia nantes, which have not true bones, but only cartilages, and the rays of whoſe fins ſcarcely differ from a membrane. In the firſt edition of the Syſtem of Nature, Linnæus wholly adopted the method of Artedi, but more reflection led him to thoſe changes which he afterwards adopted, and which he matured into that luminous and beautiful ſyſtem, of which we have ſo greatly availed ourſelves in the courſe of this work.

We may, before we mention the ſyſtem of Linnæus as it now ſtands, obſerve, that other perſons of great learning, of deep reſearch, and accurate obſervation, have propoſed different modes of arrangement, but when they have gone contrary to the method of the Swediſh naturaliſt they have uſually been deficient in ſimplicity. Thus Klein, who attempted to rival him, diſtributed fiſhes into three ſections, according as they had lungs, and viſible or inviſible gills; but his ſub-diviſions were ſo numerous and complex, that his ſcheme has never been adopted. That of Gronovius, which laſted but a few years, was founded principally on the preſence or abſence, and the number or the nature of the fins. The firſt claſs includes all the cetaceous animals, and the ſecond all the fiſhes properly ſo called. The chondropterygian, and the oſſeous or bony, form two great diviſions, and the oſſeous are ſub-divided into branchioſtegous and branchial. Theſe laſt are grouped according to the Linnæan rules, but in the formation of the genera, the number of the dorſal fins is admitted as a character. Brunnich laboured, but unſucceſsfully, to combine the original method of Artedi with the improved one of Linnæus. Scopoli ſtruck out a new path, and aſſumed the poſition of the *Anus* as the baſis of his three primary diviſions; and his ſecondary characters ſometimes coincided with thoſe of Gronovius, and ſometimes with thoſe of Linnæus; while his third ſeries of diſtinctions was drawn ſometimes from the form of the body, and ſometimes from the teeth. Another ichthyologiſt, Gouan, the profeſſor of botany at Montpelier, preſerved the Linnæan genera, but formed his greater diviſions from the union of thoſe of Linnæus and Artedi. His chief ſections are of fiſhes with *complete*, and of thoſe with *incomplete* gills. The firſt of theſe is divided into two others, *viz.* *Acanthopterygian*, and *Malacopterygian*, in each of which are arranged the apodal, the jugular, and abdominal ſpecies; and a ſimilar proceſs is followed in the ſecond ſection, which includes the *Branchioſtegous* and the *Chondropterygian*. All the authors to which we have thus briefly referred, excepting Belon, Rondelet, and Gronovius, publiſhed their works without any regular ſeries of plates illuſtrative of their deſcriptions; but there are others who have embelliſhed their volumes with very valuable figures, among whom is Seba, in his collection of subjects belonging to natural history; Catesby, in his Natural History of Carolina; Broussonet, in his Ichthyologia; and Bloch, in his Natural History of Fishes, first published at Berlin in German, and afterwards reprinted in French in 1785, forming a part of the Histoire Naturelle de Buffon. The original work of Bloch included about 600 species of fishes, which are generally described with accuracy, and figured according to the best means which he possessed, of the natural size, and beautifully coloured. In the historical departments he dwells with minuteness on those that afford food for man, or which suggest facts worthy of remark. He followed the Linnæan method, and made considerable additions to the number of genera. La Cépéde, the friend and continuator of Buffon, has executed an elaborate and extensive work on the natural history of fishes. This class of animals he divides into two secondary classes, *viz.* the cartilaginous and the osseous; each of these consists of four divisions, taken from the combinations of the presence or absence of the operculum, and of the branchial membrane: thus, according to this system, the first division of the cartilaginous includes those fishes which have neither operculum nor branchial membrane; the second, which have no operculum, but a membrane; the third, which have an operculum, but no membrane; and the fourth, those that have both. The same characters, stated in an inverse order, determine the divisions of the osseous species. Each of these divisions is again distributed into the Linnæan orders, and these in their turn are divided into the Linnæan genera, though the latter do not always correspond exactly to those of the Swedish naturalist.

According to the Linnæan system of ichthyology, as it is now arranged, and which is generally followed in the New Cyclopædia; the fins of fishes are named from their situation on the animal, *viz.* the *dorsal* or back-fin; the *pectoral* or breast-fins; the *ventral* or belly-fins; the *anal* or vent-fin; and the *caudal* or tail-fin. The *ventral-fins* are considered by Linnæus as analogous to feet in quadrupeds, and it is from the situation, presence, or absence of these fins, that he instituted the first four orders of fishes; the other two orders were formed from the nature of their *gills:* thus,

Orders.

I. Apodes are fishes entirely destitute of ventral fins.

II. Jugulares are fishes that have the ventral fins *before* the pectoral.

III. Thoracici are fishes that have the ventral fins *under* the pectoral.

IV. Abdominales are fishes that have the ventral *behind* the pectoral.

V. Branchiostegous are fishes whose *gills* are destitute of bony rays.

VI. Chondropterygious are fishes whose *gills* are cartilaginous.

The *generic* character is taken from the shape of the body, the covering, structure, figure, and parts of the head, but principally from the branchiostegous membrane (see Fish); and the *specific* character is taken from the cirri, jaws, fins, spines, lateral line, digitated appendages, tail, and colour.

In more modern systems of ichthyology, the last two orders in the Linnæan system are included in the order Pisces cartilagenei, or cartilaginous fishes, which differ from others in having a cartilaginous instead of a bony skeleton. (See Cartilaginous *Fishes*.) This method is adopted in Dr. Shaw's very instructive and entertaining work, entitled "General Zoology," to which our readers are referred.

Mr. Pennant, "in his British Zoology," describes the fishes under the three great divisions of *cetaceous*, *cartilaginous*, and *bony*. The latter, which is by far the most numerous, he sub-divides into four sections, *viz.* the *apodal*, *thoracic*, *jugular*, and *abdominal*.

PISCH, in *Geography*, a river of Poland, which runs into the Narew, near Pultusk, in the duchy of Warsaw.

PISCHMA, a river of Russia, which runs into the Tura, near Tiumen.

PISCHSTEIN, a town of Prussia, in Ermeland; 11 miles S.E. of Heilsberg.

PISCIDIA, in *Botany*, from *piscis*, a fish, and *cædo*, to slay or destroy, because it is used for the purpose of intoxicating fish, so that they are easily caught.—Linn. Gen. 367. Schreb. 486. Willd. Sp. Pl. v. 3. 909. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 4. 253. Juss. 358. Lamarck Illustr. t. 605.—Class and order, *Diadelphia Decandria.* Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, with five teeth; the two uppermost nearest each other. *Cor.* papilionaceous. Standard ascending, emarginate. Wings equal to it in length. Keel crescent-shaped, ascending. *Stam.* Filaments ten, united into a sheath split along its upper side; anthers oblong, incumbent. *Pist.* Germen superior, stalked, compressed, linear; style thread-shaped, ascending; stigma acute. *Peric.* Legume stalked, linear, with four longitudinal membranous angles, of one cell, separated into several divisions by a kind of plaits. *Seeds* few, nearly cylindrical.

Ess. Ch. Stamens all connected. Stigma acute. Legume with four wings.

1. P. *Erythrina.* Jamaica Dog-wood, or Fish-bean. Linn. Sp. Pl. 993. Willd. n. 1. Ait. n. 1. Jacq. Amer. 209. Swartz Obs. 276. (Piscipula Erythrina; Loeffl. It. 275. Ichthyomethia n. 1; Browne Jam. 296. Pseudo-acacia, siliquis alatis; Plum. Ic. 229. t. 233. f. 2. Coral arbor, &c.; Sloane Jam. v. 2. t. 176.)—Leaves pinnate; leaflets ovate.—Native of the West Indies. By road sides in Jamaica, on dry chalky hills. The bruised leaves and branches being thrown into water where there are fish, the latter become so intoxicated as to be easily taken by the hand, as they float on the surface. Many other West Indian plants possess the same property. *Jacquin.* (See Phlomis.) A large ungraceful *tree*, twenty-five feet high, easily recognised at a distance by its irregular and singular form of growth. *Leaves* alternate, deciduous, pinnate with an odd leaflet; large, downy, the leaflets ovate, or rather obovate, entire. *Clusters* numerous, erect, many-flowered, lateral or terminal. *Flowers* white, the size of a common pease-blossom. They come out in March and April, before the leaves. *Legume* four or five inches long, with very broad wings.—*P. carthaginensis*, Jacq. Amer. 210. Linn. Sp. Pl. 993. Willd. n. 2, for which Pluk. Phyt. t. 214. f. 4. is quoted, appears evidently to be merely a variety, with more obovate *leaves*. Jacquin cites for this the above figure of Plumier, which other authors make *P. Erythrina.*

2. P? *punicea.* Scarlet Fish-bean. Cavan. Ic. v. 4. 8. t. 316. Willd. n. 3.—Leaves abruptly pinnate; leaflets obtuse.—Native of South America. It has borne flowers and seed in the garden of Madrid. The *stem* is shrubby, four or five feet high. *Leaves* alternate, of numerous, uniform, smooth, elliptical leaflets, each about an inch long, glaucous beneath. *Clusters* axillary, drooping, simple, solitary. *Flowers* crimson, the size of the foregoing. *Legume* pointed, with narrow wings. Cavanilles describes the *stamens* as perfectly diadelphous, an exception to the generic character; and this circumstance, added to the abruptly pinnate *leaves*, and whole habit, make it probable that the plant is a *Robinia.* The same may be presumed of *P. longifolia*,

folia, Willd. n. 4. (Æfchynomene longifolia; Cavan. Ic. v. 4. 8. t. 315.) This is a native of New Spain, and has alfo flowered at Madrid. The habit is very like the *punicea*, but the *leaflets* are acute, and *flowers* yellow. *Legume* not obferved by Cavanilles.

Piscidia, in *Gardening*, furnifhes plants of the exotic tree kind, of which the fpecies cultivated are the Jamaica dogwood tree (P. erythrina); and the Carthaginian pifcidia (P. carthaginienfis).

Method of Culture.—Thefe plants are capable of being increafed by feeds, when they can be obtained frefh from the countries where they grow naturally. They fhould be fown upon a good hot-bed in the fpring, and when the plants come up and are fit to tranfplant, be each planted in a fmall pot filled with light earth, and plunged into a hot-bed of tanners' bark, and afterwards treated in the fame way as the other tender exotics of the fame kind.

They afford variety in the ftove.

PISCINA, in *Antiquity*, a large bafon in an open public place or fquare, where the Roman youth learnt to fwim: and which was furrounded with a high wall, to prevent the cafting of filth into it.

The word is formed from the Latin *pifcis*, *fifh*; becaufe men here imitated fifhes in fwimming, and becaufe fifhes were actually kept in fome of thefe places.

Piscina was alfo ufed for the fquare bafon in the middle of a bath.

Piscina *probatica* was a pool or refervoir of water, near the court of Solomon's temple; fo called from the Greek προβατον, *fheep*; becaufe here they wafhed the cattle, which were deftined for facrifice.

By this pifcina it was, that our Saviour wrought the miraculous cure of the paralytic. Davilier obferves, there are ftill remaining five arches of the portico, and part of the bafon of this pifcina.

Piscina, or *lavatory*, among the Turks is a large bafon placed in the middle of the court of a mofque, or under the porticos that encompafs it.

Its form is ufually a long fquare. It is built of ftone or marble, furnifhed with a great number of cocks, wherein the Muffulmans wafh themfelves before they offer their prayers; as being perfuaded, that ablution effaces fin.

Piscina, the perforated ftone ufually found in a niche on the right hand fide of the altar in our ancient churches and chapels, into which the water ufed in wafhing the hands of the officiating priefts and other facred ablutions was caft.

Piscina, in *Geography*, a town of Naples, in Abruzzo Ultra, the fee of a bifhop; 18 miles S. of Aquila.

PISCIOTA, a town of Naples, in Principato Citra; 16 miles W. of Policaftro.

PISCIPULA, in *Botany*. See Piscidia.

PISCIS, in *Ichthyology*. See Fish.

Piscis *Auftralis*, in *Aftronomy*. See Australis.

Piscis *Foffilis*, in *Ichthyology*, a name given by Johnfton to a kind of the cobitis, found buried in the fand, and dug out by the people in many parts of Germany for food. It is called by many authors the *muftela foffilis*, and by fome the *pœcilia*. It is properly a fpecies of cobitis, and is called by Artedi the *blueifh cobitis*, with five longitudinal black lines on each fide of the body. See Cobitis.

Piscis *Sancti Petri*, a name given by Jovius and fome other authors to the *faber* or *John Doree*. It is properly a fpecies of *zeus*.

Piscis *Volans*, the *Flying Fifh*, in *Aftronomy*, is a fmall conftellation of the fouthern hemifphere, unknown to the ancients, and invifible to us in thefe northern regions. See Constellation.

PISCIVOROUS Animals are fuch as feed on fifh. See Bird.

PISCO, in *Geography*, a town of Peru, in the archbifhopric of Lima and jurifdiction of Iça, Pifco, and Nafca, formerly fituated on the coaft of the South fea, but now a quarter of a league from it. An inundation of water, occafioned by an earthquake, in October 1682, deftroyed the old town, the ruins of which are ftill vifible. The whole town contains about 300 families, moft of whom are Meftizoes, Mulattoes, and Blacks; the whites being the fmalleft number. The road of Pifco is fufficiently fpacious to accommodate a royal navy, and fheltered from the ufual winds, which are thofe between the S.W. and S.E.; 110 miles S.S.E. of Lima. S. lat. 13° 55′. W. long. 76°.

Pisco, a town of European Turkey, in Moldavia, on a lake; 85 miles S. of Jaffi. N. lat. 45° 45′. E. long. 27° 38′.

Pisco *Pagani*, a town of Naples, in the province of Bafilicata; feven miles N.W. of Muro.

PISCOBAMBA, a town of South America, in the jurifdiction of Guamalies.

PISCOPIA, or Tilo, a fmall ifland in the Mediterranean; 16 miles N.W. of Rhodes. This ifland lies nearly in the middle of the interval which feparates the ifle of Rhodes from that of Stancho; and is fomewhat larger than Limonia and Narki. It has a tolerably good harbour, and feveral anchorages, which are ufeful accommodations for fhips that frequent thefe feas. The ancients called it Telos, and they highly efteemed the perfumes which were there prepared. This branch of trade is loft; but it proves the goodnefs of the foil of Pifcopia, and the mildnefs of its climate; circumftances the moft favourable to the expanfion of the fweet odour of plants and flowers. N. lat. 36° 34′. E. long. 27° 9′.

Piscopia, or *Epifcopi*, a town of the ifland of Cyprus, near a river anciently called "Lycus." In its vicinity are fome magnificent ruins, fuppofed to be thofe of the ancient city of Curias. The environs furnifh cotton and fruit trees in abundance.

PISDRI, a town of the duchy of Warfaw; 22 miles S. of Gnefna.

PISE′, a term applied to a peculiar mode of forming buildings of different kinds, but more efpecially thofe defigned for farm purpofes, with fome fort of ftiff earthy materials of a loamy quality. It is an eafy, economical, and convenient method, which had its rife on the continent, and which has been had recourfe to, for fome time, in fome parts of this kingdom, as in Bedfordfhire, Lancafhire, &c. See below.

Pisé, *Building in*, in *Rural Economy*, the name of a method of building with loamy or other earthy matters, which has long been practifed with great fuccefs, and in a very cheap manner, in fome departments of France, and which is now had recourfe to with fimilar advantage in fome parts of this country. It has been defcribed, delineated, and recommended by Mr. H. Holland in the firft volume of Communications to the Board of Agriculture, and is to be managed fomewhat in the manner directed below.

Sorts of Implements neceffary for.—In this fort of work, in addition to the common tools, fuch as fpades, trowels, bafkets, watering pots, a plumb rule, hatchet, hammer, and nails, a mould and rammer are likewife required. The following are the different conftituent parts. In the plate on pifé buildings and implements, *fig.* 1. is an outfide view of the mould; *fig.* 2, infide ditto; *fig.* 3, the head of the mould, feen without; *fig.* 4, the other face, feen within; *fig.* 5, wedges; *fig.* 6, a round ftick termed

termed the wall-gage; *fig.* 7, poſt to be ſet upright, but ſeen flatwiſe, with its tenon; *fig.* 8, the ſame on its back, alſo with its tenon; *fig.* 9, joiſts in which the mortiſes are cut, ſeen flat; *fig.* 10, the ſame, with the ſide and bottom ſeen; *fig.* 11, a mould put together, all the parts ſeen, as well as a ſmall rope; *fig.* 12, the rammer, or piſoir, for ramming the earth in mould; *fig.* 13, the ſide view of the ſame on a large ſcale; *fig.* 14, the plan of the inſtrument, ſeen on the top.

And in conſtructing the mould, it is adviſed to take ſeveral planks of light wood, each ten feet long, in order that the mould may be eaſy to handle; deal is the beſt, as being leſs liable to warp, to prevent which the boards ſhould be ſtraight, ſound, well ſeaſoned, and with as few knots as poſſible. They ſhould be ploughed and tongued, and planed on both ſides. Of theſe planks, faſtened together with four ſtrong ledges on each ſide, the mould muſt be made two feet nine inches in height; and two handles ſhould be fixed to each ſide, as at *figs.* 1 and 2. The head of the mould, which ſerves to form the angles of the building, muſt be made of two narrow pieces of wood, ploughed, and tongued, and ledged; in breadth eighteen inches, and in height three feet; and it ſhould be planed on both ſides, as at *figs.* 3 and 4, where it will be remarked, that this part of the mould diminiſhes gradually to the top, in order that the wall may be made to diminiſh in the ſame degree. It is added, that all the boards and ledges muſt be, after they are planed, ſomething more than one inch thick. And that the wedges, *fig.* 5, muſt be an inch thick, and from eight to twelve inches high; and the gage, *fig.* 6, be cut in length equal to the thickneſs of the wall that is to be erected.

It is ſtill further ſtated, that the eight ledges which are neceſſary to ſecure the two large ſides of the mould, ſerve alſo to receive eight upright poſts, ſtanding on four joiſts. The poſts, *figs.* 7 and 8 in the plate, may be made either of wood ſawed ſquare, or of round wood of any kind; ſo that one may uſe indifferently the ends of rafters, joiſts, ſmall trees, or their branches. Theſe poſts are to exceed the height of the mould by eighteen inches; they muſt, therefore, be about five feet high, including their tenons (which ſhould be ſix inches long), and three by four inches wide. That part which is to bear againſt the ledges of the mould muſt be made flat and ſtraight, the other ſides need not be worked with ſo much truth. And the joiſts may be of the ſame ſort of ſtuff, three feet ſix inches long, three inches and a half broad, and three inches thick. On the broad part muſt be made the two mortiſes, as at *fig.* 9 in the plate, ten inches and a half long, and rather more than an inch wide, and at each end three inches and a half muſt be left beyond the mortiſes, ſo that the interval between them will be fourteen inches. Theſe dimenſions muſt be obſerved, in order that the two ſides of the mould may incline towards each other, and the thickneſs of the wall be gradually diminiſhed, till it is reduced to fourteen inches at the roof. Of courſe the dimenſions for the joiſts are theſe:

	ft.	in.
The two ends, remaining beyond the mortiſes, three inches and a half each -	0	7
The two mortiſes, ten inches and a half each -	1	9
The interval between the mortiſes -	1	2
Total length of the joiſt	3	6

It may be noticed, that the elevation of the whole machine is ſeen at *fig.* 11 in the plate; and the following is a liſt of its ſeveral parts, enumerated in the ſame order that the workmen muſt follow, when they erect the mould on a wall. A, ſtone foundation, eighteen inches thick, on which the wall of earth is to be raiſed; B, the joiſts placed acroſs the foundation wall; C, C, the two ſides of the mould, including between them three inches of the foundation wall; D, D, the two upright poſts, the tenons of which fit into the mortiſes of the joiſt; E, the wall-gage, which fixes the width of the mould at the top, and which is ſhorter than the width of the wall at the bottom, to regulate the diminution of the wall to be erected; F, a ſmall cord, ſomething leſs than half an inch diameter, making ſeveral turns round the poſts; G, a ſtick, which, by being wound round, faſtens the cord, and holds the poſts tight together; H, H, wedges, which enter into the mortiſes in the joiſts, and keep the poſts and the mould firmly fixed againſt the wall. But though ſuch is the proceſs of erecting the mould, a contrary order muſt be obſerved in taking it to pieces. The rope muſt be looſened, the wedges taken out, and the poſts, the mould, and the joiſts removed, in order to refix the whole again. And the rammer with which the earth is rammed into the mould, is a tool of the greateſt conſequence, and on which the firmneſs and durability, in ſhort, the perfection of the work depends, and in making which more difficulty will be found than is at firſt apprehended. It ſhould be made of hard wood, either aſh, oak, beech, walnut, &c. or, what is preferable, the roots of either of theſe ſorts of wood.

And in regard to the nature of this ſort of work, it differs very eſſentially from that miſerable way of building with clay or mud mixed with hay or ſtraw, which is often ſeen in country villages; it contains all the beſt principles of maſonry, together with ſome rules peculiar to itſelf. At *fig.* 15, in the plate, is repreſented the plan of a houſe, the building of which is regularly deſcribed according to this method. The foundation may be made of any kind of maſonry that is durable, and muſt be raiſed to the height of two feet above the ground; which is neceſſary to ſecure the walls from the moiſture of the earth, and the ſplaſhing of the rain, which will drop from the eaves of the roof. When theſe foundation walls are made level, and eighteen inches thick, mark upon them the diſtances at which the joiſts are to be ſet for receiving the moulds; thoſe diſtances ſhould be three feet each from centre to centre. Each ſide of the mould being ten feet long will divide into three lengths of three feet each, and leave ſix inches at each end, which ſerve to lengthen the mould at the angles of the houſe, and are uſeful for many other purpoſes. After having ſet the joiſts in their places, the maſonry muſt be raiſed between them ſix inches higher, that is, to a level with the joiſts; here will, therefore, upon the whole, be a baſe of two feet and a half, which in moſt caſes will be found more than ſufficient to hinder the rain, froſt, ſnow, or damp, from injuring the walls. Raiſe the mould in the manner mentioned above, immediately on this new maſonry, placing it over one of the angles of the wall. The head of it, which is to be placed againſt the angle, ſhould have eighteen inches in breadth at the bottom, and only ſeventeen inches and a half at the top; thus the ſides of the mould will incline towards each other, and produce that diminution in the thickneſs of the wall, which is uſual in buildings of this nature. The wedges muſt then be driven in, and the poſts well fixed by cords, and the head of the mould ſecured by iron pins, when the whole is ready for the workmen to begin their work.

In addition it is ſtated, that a workman ſhould be placed in each of the three diviſions of the mould, the beſt being placed at the angle. He is to direct the work of the other two,

two, and by occafionally applying a plumb-rule, to take care that the mould does not fwerve from its upright pofition. The labourers who dig and prepare the earth muft give it in fmall quantities to the workmen in the mould, who, after having fpread it with their feet, begin to prefs it with the rammer. They muft only receive at a time fo much as will cover the bottom of the mould to the thicknefs of three or four inches. The firft ftrokes of the rammer fhould be given clofe to the fides of the mould, but they muft be afterwards applied to every other part of the furface; the men fhould then crofs their ftrokes, fo that the earth may be preffed in every direction. Thofe who ftand next to one another in the mould fhould regulate their ftrokes fo as to beat at the fame time under the cord, becaufe that part cannot be got at without difficulty, and muft be ftruck obliquely; with this precaution the whole will be equally compreffed. The man at the angle of the wall fhould beat carefully againft the head of the mould, and for the fake of the appearance, or perhaps to increafe the ftrength of the building, it is ufual to fpread every fix inches high a layer of mortar near the head, in imitation of the joints of ftone-work. Care muft be taken, that no frefh earth is received into the mould till the firft layer is well beaten, which may be afcertained by ftriking it with the rammer; the ftroke fhould leave hardly any print on the place. They muft proceed in this manner to ram in layer after layer till the whole mould is full. When this is done, the machine may be taken to pieces, and the earth which it contained will remain firm and upright, about nine feet in length, and two feet and a half in height. The mould may then be replaced for another length, including one inch of that which has firft been completed: the regular manner of joining the different lengths may be feen in the geometrical elevations in the plate at *fig.* 16, and more particularly at *fig.* 17, where it will be obferved, by the letters A and B, that no joints are left in this work, as the different lengths are united, and made to prefs one on the other. In the fecond length, and moft of the following, the head of the mould is ufelefs; it is only made ufe of at the angles. As foon as the workmen have gone round the whole building, taking the mould to pieces and putting it together again fucceffively, they fhould begin upon the partition marked C in the fame plate *fig.* 15, where the head of the mould muft be ufed, as the door jambs are fquared like the angles of the wall. The jamb next to the exterior wall, which is too narrow to be made of pifé, can eafily be made of wood, brick, or ftone. And the firft courfe being thus completed proceed to the fecond, and here it muft be obferved, that if in laying the firft courfe the work begin with one angle, as the angle A, *fig.* 15, and proceed towards E, it muft, for the fecond courfe, begin with A, and proceed towards B, and fo in each fucceffive courfe it muft proceed in a direction contrary to that of the preceding. It may eafily be conceived, that with this precaution the joints of the feveral lengths will be inclined in oppofite directions, which will contribute very much to the firmnefs of the work. There is no reafon to fear overcharging the firft courfe with the fecond, though but juft laid; for three courfes may be laid without danger in one day; mark the grooves for receiving the joints in the firft courfe, at the diftance of three feet from one another, but not immediately over the former grooves, but over the middle points between them, as feen at *fig.* 17. in the plate. Thefe grooves muft be cut with a pick-axe, and the fecond courfe completed in the fame manner as the former, except that it muft proceed in a contrary direction, as was before obferved, and that the head of the mould and wall-gage muft be diminifhed, in order that the fame inclination of the fides to one another that was given to the firft courfe, may be preferved in this fecond. It muft, however, be remarked, that this fecond courfe is not to be continued without interruption like the firft, as it is neceffary that the partition-wall fhould join or bond into the exterior wall; or rather, that all the walls in the building, whether outfide or partition-walls, which meet at an angle, fhould crofs each other at every courfe. In purfuance, therefore, of this rule, when the work has been advanced from A to C, or perhaps not quite fo far as C, leave the exterior wall, and turn the mould to the partition, applying the face of it to C. This will appear more clearly by the letter G, in the fame plate *fig.* 17. When the work has been carried on along the partition-wall as far as the door, bring back the mould to the part which remained unfinifhed in the exterior wall, marked C, at *fig.* 15. in the plate; and after having filled up that fpace, carry the mould on beyond the partition-wall, and complete the courfe. The reafon of the partition-wall on the fide oppofite to C, not being connected in the fame manner with the interior wall, is that it ought to be made of wood or brick-work, and not of this material, but the third courfe muft be carried over the door, and join into the wall, as above. It has been obferved, that this defcription of the two firft courfes is equally applicable to all the others, and will enable any perfon to build a houfe, with no other materials than earth, of whatever height and extent he pleafes to have it.

Befides this, it may be remarked that the gables cannot be croffed, as thefe are detached from one another; but as their height is fo inconfiderable, and they are befides connected together by the roof, this is not of any confequence. They may be made without any difficulty, by merely making their inclination in the mould, and working the earth accordingly. It has been obferved, that each courfe will be two feet and a half high, if the mould is two feet nine inches; for the mould muft include three inches of the courfe beneath. For this reafon the grooves are made fix inches deep, though the joifts are only three inches in thicknefs. If the directions which have been given for diminifhing the thicknefs of the walls are obferved, that thicknefs will be reduced to fifteen inches at the roof, in a houfe (like that of which a defign is annexed) confifting of fix courfes; for in each courfe there will be an inclination of half an inch. The gables might have been reduced to fourteen inches only in thicknefs, as an interval of fourteen inches only was left between the mortifes of the joifts: and by increafing or diminifhing that interval the thicknefs of the walls may be regulated at pleafure.

It is noticed that in this mode of building, according to the account of the Rev. Mr. Jancour, as practifed at Montbrifon, the capital of the Forêts in France, as tranfmitted to the Board of Agriculture, the earth is pounded as much as poffible, in order to crumble any ftones therein; clay is added thereto in a fmall quantity, about one-eighth part. It is all beaten and mixed up together by repeated blows with a mallet about ten inches broad, ten or fifteen long, and two inches thick. The earth being thus prepared and flightly wetted, the foundation of the houfe is dug for; this is laid with ftone, and when it is about one foot high above the furface of the ground, planks are arranged on each fide, which are filled with the earth intended for the wall. It is ftrongly beaten; and this method is continued fucceffively all round the building. The walls have more or lefs thicknefs, according to the fancy of the owner; he has feen them of fix and of eighteen inches thick. Some builders interfperfe from fpace to fpace a thin layer of lime. If feveral ftories are intended in fuch erections, they do not fail to place beams to support the floors before they build higher; the windows and doors are attended to in the fame manner. Of fuch buildings he never faw any confifting of more than two ftories at moft; generally they have but one befides the ground-floor. When the building is thus finifhed, it is left for fome months to dry: then fuch as wifh to make the building more folid and durable, give it a rough-caft coating on the outfide with lime and fand.

And in regard to the manner of forming the openings for the doors and windows, they fhould be left at the time of building the walls. This may be done by placing within the mould either two or one of the heads, (as reprefented *figs.* 3 and 4 in the plate,) as may be neceffary, wherever the wall is to terminate and the opening commence. They fhould be made floping a little, in order to leave room for the frames and fafhes. And the exterior decorations of the windows and doors are ufually made, by the rich, of ftone or brick, and by the poor of wood, which latter have a bad effect on the appearance of the houfe, as wood will never unite well with pifé-work; and notwithftanding the greateft precautions, the exterior covering will break and fall off the wood; whereas ftone or brick-work unite perfectly with the pifé, and retain their plafter, and of courfe the paint, of which it forms the ground. The chimney-pieces of brick or ftone are laid and united with the walls in the fame manner as in common buildings; and the flues are alfo very firmly connected with them, being made of brick-work. But a very particular advantage is, that the apartments may be very handfomely finifhed, without making any jambs to the infide doors, either of ftone, brick, or wood. The finifhing of the earthen walls will make jambs unneceffary, and it is not requifite to be at the expence of any other finifhing, as the doors may be hung on the grounds or wainfcot of the apartment, as may be found neceffary.

The particular Nature of, and Manner of preparing the Earth.—It is further obferved that beating, or compreffion, is ufed in many different forts of work; the ancients employed it in making their rough walls; the Italians employ it for the terraces which cover their houfes; the Moors for all their walls; the Spaniards, the French, and others, for fome of the floors of their apartments. The intent of the ancient architects, when they recommended the beating of cement, and other compofitions ufed in building, was to prevent them from fhrinking and cracking; and it is employed for the fame purpofe in the walls which are made of earth. The beater, by repeated ftrokes, forces out from the earth the fuperfluous water which is contained, and clofely unites all the particles together, by which means the natural attraction of thofe particles is made powerfully to operate, as it is by other natural caufes, in the formation of ftones. Hence arifes the increafing ftrength and aftonifhing durability which houfes of this kind are found to poffefs. It is added that upon beating a fmall portion of earth, and weighing it immediately afterwards, it was found to contain thirty-nine pounds and a half; fifteen days after it had loft four pounds and a quarter; in the fpace of another fifteen days it loft but one pound; and in fifteen days after that its weight diminifhed only half a pound. In the fpace of about forty-five days the moifture was completely evaporated, and its weight was diminifhed about one-eighth; confequently only one-eighth of the whole mafs was occupied by moifture, and this fmall proportion cannot at all affect the folidity and confiftency of the earth fo treated. This experiment is alfo fufficient to fhew the difference between this kind of building, and that vulgar kind called in England "mud-walling;" the latter cannot be executed without adding a great deal of water, to foften the materials employed, which entirely deftroys their confiftency; the water, which occupies a confiderable fpace in the mud, leaves, in evaporating, an infinite number of pores or little cavities, and thus the walls become weak and brittle, and incapable of fupporting feveral ftories, or fuch ponderous weights as the beaten earth or pifé can fuftain.

And with regard to the quantity or height of walling of this fort that may be done in one day, it is ftated, that three courfes, of about three feet each, may be laid one over the other in the courfe of a day; fo that a wall of earth, of about eight or nine feet, or one ftory high, may be raifed in the fame time. Experience has proved, that as foon as the builders have raifed their walls to a proper height for flooring, the heavieft beams and rafters may, without danger, be placed on the walls thus newly made; and that the thickeft timber of a roof may be laid on the gables of this fort the very inftant they are completed.

Further, on the proper forts of earth for this ufe, it is ftated, that, 1ft. All earths in general are fit for fuch ufe, when they have not the lightnefs of poor lands, nor the ftiffnefs of clay. 2dly. All earths fit for vegetation. 3dly. Brick-earths; but thefe, if they are ufed alone, are apt to crack, owing to the quantity of moifture which they contain. This, however, does not hinder perfons who underftand the bufinefs from ufing them to a good purpofe. 4thly. Strong earths, with a mixture of fmall gravel, which for that reafon cannot ferve for making either bricks, tiles, or pottery. Thefe gravelly earths are very ufeful; the beft work of this fort is made of them. And it is faid, that from the following marks may be known what earths are fitteft to be employed by themfelves. When thefe have been defcribed, it will remain to point out fuch as muft be mixed with others, in order that they may acquire the neceffary quality. And the following appearances indicate that the earth in which they are found is fit for building: when a pick-axe, fpade, or plough, brings up large lumps of earth at a time; when arable lands lie in clods or lumps; when field-mice have made themfelves fubterraneous paffages in the earth; all thefe are favourable figns. When the roads of a village, having been worn away by the water continually running through them, are lower than the other lands, and the fides of thofe roads fupport themfelves upright, it is a fure mark that the work may be executed in that village. One may alfo difcover the fitnefs of the foil, by trying to break with one's fingers the little clods of earth in the roads, finding a difficulty in doing it, or by obferving the ruts of the road in which the cart-wheels make a fort of pifé by their preffure: whenever there are deep ruts on the road, one may be fure of finding abundance of proper earth. And proper earth is found at the bottom of the flopes, on low lands that are cultivated, becaufe every year the rain brings down the fat or good earth. It is frequently found on the banks of the rivers; but above all, it is found at the foot of hills where vines are planted, and of all cultivated lands which have much flope. In digging trenches and cellars for building, it generally happens that what comes out of them is fit for the purpofe of this fort of building. But as it may fometimes happen that earth of a proper quality is not to be found on the fpot where it is intended to build, it becomes of importance to attend to the method of mixing earths; for though the earth which is near at hand may not of itfelf be proper, it is very probable that it may be rendered fo by the mixture of a fmall quantity of another earth fetched from a diftance. The principle on which a mixture muft be made is very fimple; ftrong earths muft be tempered with light; thofe in which clay predominates, with others that are compofed more of chalk and fand; and thofe of a rich, glutinous fubftance, with

with others of a poor and barren nature. The degrees in which thefe qualities of the earth prevail, muft determine the proportions of the mixture ; which it is impoffible here to point out for every particular cafe, but which may be learnt by a little practice. And it will not be amifs to mix with the earth fome fmall pebbles, gravel, rubbifh of mortar, or in fhort any fmall mineral fubftances ; but none of the animal or vegetable kind muft be admitted. Such hard fubftances bind the earth firmly between them, and being preffed and preffing in all directions, contribute very much to the folidity of the whole ; fo that well-worked earth, in which there is a mixture of gravel, becomes fo hard at the end of two years, that a chiffel muft be ufed to break it, as if it was freeftone, or other folid ftone.

The following experiments are detailed in order to afcertain the qualities of any earth.

Experiment 1.—Take a fmall wooden tub or pail, without a bottom, dig a hole in the ground of a court or garden, and at the bottom of that hole fix a piece of ftone, flat and level ; place your tub upon the ftone, fill around it the earth that has been dug out to make the hole, and ram it well, that the tub may be enclofed, to prevent its burfting. Then ram into the tub the earth you mean to try ; putting in, at each time, about the thicknefs of threee or four fingers' breadths ; when this is well rammed, add as much more, and ram it in the fame manner, and fo the third and fourth, &c. till the earth is raifed above the brim. This fuperfluous earth muft be fcraped off extremely fmooth, and rendered as even as the under part will be, which lies on the ftone. Loofen with a fpade the earth round the tub, and you will then be able to take it out, and with it the compreffed earth that it contains ; then turn the tub upfide down, and if it is wider at the top than at the bottom, as fuch veffels ufually are, the pifé will eafily come out ; but if it fhould happen to ftick, let it dry in the air about twenty-four hours, and you will then find that the earth is loofe enough to fall out of itfelf. You muft be careful to cover over this lump of pifé with a little board ; for though a fhower of rain, falling in an oblique direction, will not injure it, yet it may be a little damaged, if the rain falls perpendicular, and efpecially if it remains upon it. Leave the lump expofed to the air, only covered with a board or flat ftone, and if it continues without cracking or crumbling, and increafes daily in denfity and compactnefs, as its natural moifture decreafes, you may be fure that the earth is fit for building. But you muft remember that it is neceffary that the earth employed fhould be taken from a little below the furface of the ground, in order that it may be neither too dry nor too wet : it muft be obferved alfo, that if the earth is not well preffed around the outfide of the tube before it is filled, though the hoops were of iron, they would burft, fo great is the preffure of the beaten earth againft the mould, of whatever fize it may be.

Experiment 2.—This trial may be made in the houfe. Having brought from a field the earth you want to try, prefs it in a ftone mortar, with a peftle of wood, brafs, or iron (the latter is beft); or with a hammer ; fill the mortar above the edge, and then with a large knife, or fome other inftrument, take away the fuperabundance of the earth even with the brim. If you find then that the earth will not quit the mortar, you muft expofe it to the fun, or near a fire ; and when it is fufficiently dry, it may be taken out without difficulty by turning the mortar upfide down on a flat ftone, or the floor. It will have the fhape of the mortar, and if expofed as above directed, will fhew the quality of the earth.

Experiment 3.—Prefs with the end of a ftick, or cane, your earth in a little box, round which you had better firft tie a piece of packthread, left it fhould burft in the operation ; when you have filled it above its brim, cut off the overplus with a knife ; you will undoubtedly be obliged to break the box to get it out, unlefs you had rather wait, and let it dry in the air, in the fun, or before a fire. It will take the exact form of the box, be it round, fquare, or oval ; if your earth be red, or any other colour, that which is enclofed in the box will ftill remain the fame. It is not improper to remark, that the colour of the earth neither adds to nor diminifhes the goodnefs of the pifé, therefore every proprietor may be at eafe on that head. Befides, every perfon in walking on his ground, may make little balls of earth, and prefs them as tight as he can between his hands. If he brings them home and puts marks on them, he will by that means know the quality of every piece of land, and alfo be a judge of the mixture it will be neceffary to make.

Further, in preparing the earth, all the operations are very fimple and eafy : there is nothing to be done but to dig up the earth with a pick-axe, break the clods with a fhovel, fo as to divide it well, and then lay it in a heap ; which is very neceffary, becaufe as the labourers throw it on that heap, the lumps of earth and large ftones roll to the bottom, where another man may break them, or draw them away with a rake. He muft obferve, that there fhould be an interval of about an inch and a quarter between the teeth of the rake, that the ftones and pebbles of the fize of a walnut, or fomething more, may efcape, and that it may draw off only the largeft. If the earth that has been dug has not the proper quality, which is feldom the cafe, and that it is neceffary to fetch fome better from a diftance, then the mixture muft be made in this manner : one man muft throw one fhovel full of the beft fort, while the others throw five or fix of the inferior fort on the heap, and fo more or lefs, according to the proportion which has been previoufly afcertained. No more earth fhould be prepared than the men can work in one day, or a little more, that they may not be in want ; but if rain is expected, you muft have at hand either planks, mats, or old cloths to lay over the heap of earth, fo that the rain may not wet it ; and then as foon as the rain is over, the men may refume their work, which, without this precaution, muft be delayed : for it muft be remembered, that the earth cannot be ufed when it is either too dry or too wet, and therefore if the rain fhould wet it after it has been prepared, the men will be obliged to wait till it has recovered its proper confiftency ; a delay which would be equally difadvantageous to them and their employer. When the earth has been foaked by rain, inftead of fuffering compreffion, it becomes mud in the mould ; even though it be a little too moift, it cannot be worked : it fwells under the blows of the rammer, and a ftroke in one place makes it rife in another. When this is the cafe, it is better to ftop the work, for the men find fo much difficulty, that it is not worth while to proceed. But there is not the fame neceffity of difcontinuing the work when the earth is too dry, for it is eafy to give it the neceffary degree of moifture ; in fuch a cafe it fhould be fprinkled with a watering-pot, and afterwards well mixed together ; it will then be fit for ufe. It has already been obferved, that no vegetable fubftances fhould be left in the earth ; therefore in digging, as well as in laying the earth in a heap, great care muft be taken to pick out every bit of root, great and fmall, all fprigs and herbs, all bits of hay and ftraw, chips or fhavings of wood, and in general every thing that can rot, or fuffer a change in the earth after it has been prepared in this manner for ufe in building.

The Kind of Timber neceffary.—It is ftated that, in order to to make good walls, it is not fufficient that the earths be well beaten, but they muft be well united together. In houfes of brick or ftone, to confolidate their parts, they make ufe of angles and binders of free-ftone, and of iron braces, and cramp irons, which are very expenfive; but here the binders coft very little; they confift only of thin pieces of wood, a few cramps and nails, and thefe are fufficient to give the greateft ftability to buildings of pifé. It is added, that the firft courfe A, *figs.* 15 and 16 in the plate, being laid on the front and inner walls of a houfe, then begin the fecond; and if, for the inferior courfe, the mould has been directed from A to E, it muft, for this fecond, be directed from A to F, as has been explained above. But before this fecond courfe is begun, lay at the bottom of the mould a board about five or fix feet long, refting on the angle A, and extending lengthwife towards B. This board muft be rough as the fawyers have left it, fomething lefs than an inch thick, and in breadth about eight, nine, or ten inches, fo that there may remain on each fide four or five inches of earth, if the wall is eighteen thick; by this means the board will be entirely concealed in the body of the wall. When thus placed, neither the air nor damp can reach it, and of courfe there is no danger of its rotting. This has often been proved by experience, as in taking down old houfes of pifé fuch boards have always been found perfectly found, and many that had not even loft the colour of new wood. It is eafy to conceive how much this board, from the preffure of the work raifed above it, will contribute to bind together the two lengths A and B, and to ftrengthen the angle A; but this is not all, it is ufeful (particularly when the earth is not of a very good quality) to put ends of planks into the pifé after it has been rammed about half the height of the mould. Thefe ends of planks fhould be only ten or eleven inches long, to leave as before a few inches of earth on each fide of the wall, if it is eighteen inches thick; they fhould be laid crofswife (as the plank before-mentioned is laid lengthwife) over the whole courfe, at the diftance of about two feet from one another, and will ferve to equalize the preffure of the upper parts of the works on the lower courfe of the pifé, or rammed earth. But thefe boards need only be placed at the angles of the exterior wall, and in thofe parts where the courfes of the partition-walls join to thofe of the exterior wall; the fame directions that have here been given for the fecond courfe, muft be obferved at each fucceeding courfe, up to the roof. By thefe means, it is feen, an innumerable quantity of holders or bindings will be formed, which fometimes draw to the right, fometimes to the left of the angles, and which powerfully unite the front walls with thofe of the partitions; the feveral parts deriving mutual fupport from one another, and the whole being rendered compact and folid. Hence thefe houfes, made of earth alone, are able to refift the violence of the higheft winds, ftorms, and tempefts. The height that is intended to be given to each ftory being known, boards of three or four feet in length fhould be placed before-hand in the pifé, in thofe places where the beams are to be fixed, and as foon as the mould no longer occupies that place, the beams may be laid on, though the pifé be frefh made; little flips of wood, or boards, may be introduced under them, in order to fix them level. The beams thus fixed for each ftory, the pifé may be continued as high as the place on which you intend to erect the roof of the building.

And befide the ufe of this fort of material in the building of houfes, it may be applied to the raifing of walls for different forts of inclofures, as parks, gardens, yards, &c. in which the mould muft be fixed in an angle, or againft a building, if the wall is to reach fo far, and the workmen muft proceed from thence to the other extremity of the wall; and when they have finifhed the firft courfe, they muft raife the mould to make the fecond, returning to the place where they began the firft. But when a very great inclofure is to be made, as for inftance a park wall, then, for the fake of fpeed, it is neceffary to fet feveral moulds and men at work. In fuch a cafe, a mould fhould be placed at each end, and the number of men be doubled; they will work at the fame time, and meet in the middle of the wall, where they will clofe the firft courfe; after which each fet of men raife their mould to make the fecond; and both fetting out from the middle continue working, in oppofite directions, towards the ends where they firft began.

In this way houfes may be built, which are ftrong, healthy, and very cheap; and which will laft a great length of time, as the author fays, he had pulled down fome of them, which, from the title deeds in the poffeffion of the proprietors, appeared to be 165 years old, though they had been ill kept in repair. The rich traders of Lyons have, he obferves, no other way of building their country-houfes. An outfide covering of painting in frefco, which is attended with very little expence, conceals from the eye of the fpectator the nature of the building, and is a handfome ornament to the houfe. That method of painting has more frefhnefs and brilliancy than any other, becaufe water does not impair the colours. No fize, oil, or expence is required, manual labour is almoft all it cofts, either to the rich or poor. Any perfon may make his houfe look as fplendid as he pleafes for a few pence laid out in red or yellow ochre, or in other mineral colours. And he adds that ftrangers, who have failed upon the Rhone, probably never fufpected that thofe beautiful houfes which they faw rifing on the hills around them, were built of nothing but earth; nay, many perfons have dwelt for a confiderable time in fuch houfes, without ever being aware of their fingular conftruction. Farmers in that country generally have them fimply white-wafhed, but others, who have a greater tafte for ornament, add pilafters, window-cafes, pannels, and decorations of various kinds.

Befides, it is fuggefted that there is every reafon for introducing this method into all parts of the kingdom; whether we confider the honour of the nation as concerned in the neatnefs of its villages, the great faving of wood which it will occafion, and the confequent fecurity from fire, or the health of the inhabitants, to which it will greatly contribute, as fuch houfes are never liable to the extremes of heat or cold. It is attended with many other circumftances that are advantageous to the ftate, as well as to individuals. It faves both time and labour in building, and the houfes may be inhabited almoft immediately after they are finifhed; for which latter purpofe the holes made for the joifts fhould not be clofed up directly, for the air, if fuffered to circulate through them, will dry the walls more fpeedily. And the durability of this fort of building is fully fhewn by the ftatement of the Rev. Mr. Jancour, who refided at Montbrifon in France, where, he fays, the church was the moft remarkable in this ftyle of building; it is about eighty feet long, forty feet broad, and fifty feet high; the walls built in *pifé* eighteen inches thick, and *crépé*, or rough-caft on the outfide with lime and fand. Soon after his arrival, the church, by fome accident, was deftroyed by fire, and remained unroofed for about a twelvemonth, expofed to rains and froft. As it was fufpected that the walls had fuftained much damage, either by fire or the inclemency of the feafon, and might fall down, it was determined to throw them down partially, and leave only the lower parts ftanding; but

but even this was not done, he adds, without much difficulty, fuch was the firmnefs and hardnefs thefe walls had acquired, the church having ftood above eighty years; and all the repairs required, were only to give it, on the outfide, every twelve or fifteen years, a new coating of rough-caft. And it is further remarked, that befides the advantages of ftrength and cheapnefs, this method of building poffeffes that of fpeed in the execution. It is found that a mafon ufed to work, can, with the help of his labourer, when the earth lies near, build, in one day, fix feet fquare of the pifé. If two men can build, in one day, fix feet fquare, it is evident that fix men, which is the neceffary number to work the mould, (*viz.* three in the mould, and three to dig and prepare the earth,) will build, in the courfe of fixteen days, or three weeks at moft, fuch a houfe as is feen in the plate, at *figs.* 15 and 16, containing 228 fquare feet of wall; a very fhort time therefore is fufficient for a man to build himfelf a folid and lafting habitation. Thefe facts, which have been proved by numberlefs inftances, afford a proportion by which every one may determine the time that his houfe or wall will take in building, having firft afcertained the number of feet it will contain. Thus, if he wifhes to have a wall 540 feet long, and fix feet high, it will be finifhed in one month, with one fingle mould, and fix men; but if he doubles both mould and men, it will be done in fifteen days. Thefe are fimple but neceffary inftructions, for they will prevent the inconvenience to which many are expofed from having the completion of their building protracted beyond the time that they originally expected. All perfons who wifh to build, may now contract with the builder that the work fhall be finifhed on fuch a day; or that he fhall indemnify them for all the loffes which they may incur from his failure to make good his engagement in that refpect.

And in regard to the outfide covering of plafter, which is proper for rammed earth or pifé walls, it is quite different from that which is made ufe of on any other walls: it is neceffary, too, to take a proper time for laying it on. When a houfe of this fort has been begun in February, and completed in April, the covering may be laid on in the autumn, that is to fay, five or fix months after it is finifhed; or if it is finifhed in the beginning of November (at which time the mafons generally give over working) it may be laid on in the fpring. In this interval the walls will be fufficiently dried; but it muft not be imagined that it is the drought or cold that extracts the moifture from an earthen wall; it is only the air, which is of itfelf fufficient either in fummer or winter, to dry a pifé or rammed-earth wall thoroughly. If the plafter be laid over them before the dampnefs is entirely gone, it muft be expected that the fweat of the walls will caft it off.

But in order to prepare the walls for plaftering, they fhould be indented with the point of a hammer, or hatchet, without being afraid of fpoiling the furface left by the mould; all thofe little dents muft be made as clofe as poffible to each other, and cut in, from top to bottom, fo that every hole may have a little reft in the inferior part, which will ferve to retain and fupport the plafter. And to do it the mafons muft make a fmall fcaffold in the holes which the joifts of the mould have left at *figs.* 2 and 3 in the plate. This fcaffold may be made in a few minutes, and when, with the affiftance of it, they have indented the upper parts of the houfe, they muft run a ftiff brufh over the indented furface, to remove all duft or loofe earth. The walls, when thus prepared, may receive the plaftering; but it fhould be obferved that there are two kinds of plafter that may be ufed in the pifé; rough-caft, and ftuccoing. Rough-caft confifts of a fmall quantity of mortar, diluted with water in a tub, to which a trowel of pure lime is added, fo as to make it about the thicknefs of cream. Stucco is nothing more than poor mortar, which the labourers make up in a clean place near the lime-pit, and carry it to the mafons on the fcaffold.

Befides, for the purpofe of rough-cafting one workman and his labourer are fufficient; the workman only fprinkles with a brufh the wall he has indented, fwept, and prepared; after that he dips another brufh, made of bits of reed, box, &c. into the tub which contains the rough-caft, and throws with this brufh the rough-caft againft the wall; when he has covered, with as much equality as poffible, fo much of the wall as is within his reach, he lowers his fcaffold, and ftops up the holes of the joifts with ftones, or old plafter, &c. does as before, and continues lowering his fcaffold in the fame manner till he comes to the bottom of the houfe. This rough-caft, which is attended with fo little trouble and expence, is notwithftanding the beft cover that can be made for pifé or rammed-earth walls, and for all other conftructions; it contributes to preferve the buildings, and though not beautiful, has the recommendation of being attainable by people in moderate circumftances. It is the peculiar advantage of thefe buildings that all the materials they require are cheap, and all the workmanfhip fimple and eafy to be performed.

But in regard to the procefs of ftuccoing it is very different; two workmen and two labourers are requifite, the two workmen being on the fcaffold, and one of the labourers making up the mortar, while the other carries it with water, and ferves the workmen. One of the workmen holds in his right hand a trowel, and in the other a brufh, with which he fprinkles the wall, having beforehand indented and fwept it; after that, he lays on a few trowels full of ftucco, which he fpreads as much as poffible with the fame trowel, and then he lays on more, and thus continues his work. The fecond workman has alfo in his left-hand a brufh, and in his right-hand a fmall wood float; he fprinkles water over the mortar that his partner has fpread, and rubs over that part he has wetted with his wood float. Thus the firft workman lays on the plafter, and advances gradually, the fecond follows and polifhes; one labourer makes up the ftucco, the other carries it, and ferves the workmen. By this procefs the fmootheft, fineft, and cheapeft plaftering is made. And at the fame time that the plafter is laid on, it may alfo be whitened by the ufe of lime alone, which is alfo an object of economy, fince it faves white lead, &c. For this purpofe dilute lime in a tub of very clear water, and let a labourer take fome of it in a pot, and carry it to the workmen, who muft lay it on with a brufh; this, as well as all other colours, adheres to the plafter, and never falls, although it is ufed with water only, without fize or oil. This is to be attributed to the precaution of laying on the colour whilft the plafter is ftill wet; as it grows dry, it incorporates the mineral colours with its own fubftance, and makes them laft as long as itfelf. This is on the principles of frefco colouring or painting, which is very neat.

And it is added, that the lime is of very general utility; it is ufed in building, in plaftering, and in white-wafhing; and it will appear that for painting alfo it may be employed with advantage. Thofe who intend to build, therefore, ought always to have a ftore of it by them, and it fhould be flaked a long time before it is ufed, to prevent crevices and bliflers, which, without this precaution, will arife in the plafter, and give it fo difagreeable an appearance, that it will be neceffary to do the work over again. The reafon of it is this, there will always remain in the lime fome particles that have not been flaked in the pit; all the ftones are not

entirely

entirely reduced to lime in the kiln, and thofe ftones will refift the action of the water for a time, and will burft from the plafter after it has been laid, leaving the crevices above-mentioned. This inconvenience will not happen if the lime, after being flaked, is left to ftand fome time before it is ufed. Indeed it will not be amifs to let it lie by a whole year, or longer, when it can be done with convenience. Befides this, it is obferved on the painting in frefco of the outfide covering, that that kind of painting which is known by this name, is the moft beautiful and cheapeft of any, and it is that which the author recommends for the decoration of pifé or rammed-earth buildings. The moft celebrated painters were very partial to it, and Rome furnifhes many excellent models, which fhould engage us to reftore it from that neglect and difufe into which it has, without reafon, been fuffered to fall. And that, whoever wifhes to have his houfe painted in frefco, muft have a painter ready, and place him on the fcaffold with the workmen. The latter lay on the mortar, as before directed, and are attentive to fpread it very even, to receive the paint. When they have finifhed one part, they fufpend their work, to give the painter time to do his; for if they continued working on, the painter, who cannot go on fo faft as they, would find the mortar too dry, and the colours would not incorporate with it. It is abfolutely neceffary that the plafterer's work fhould be fubordinate to that of the painter; it is fometimes fo arranged, that the latter work while the former are gone to their meals; and when in his turn he retires from work, he traces out the part that the plafterers are to cover during his abfence, forefeeing how much he fhall be able to paint in the courfe of the day. All thefe precautions are taken to prevent the too fpeedy drying of the mortar, and to feize the proper time to lay on the colours while it is frefh.

And in order to make the colour meant to be given to a country-houfe, dilute in a large tub a fufficient quantity of lime which has been flaked a long time; and alfo dilute in another tub or pot fome ochre, either yellow, red, or any other mineral colour, but always in very clear water; after which, pour a little of the colour into the large tub, and ftir it about with a ftick, fo as to mix it well with the lime; take fome of the colour on a brufh, and try it on a board or wall; if it is too deep or too light, add frefh lime or colour from the tub, and by repeated trials bring it to the tint that is wifhed to be given to the houfe. The colour being made for the body of the houfe, the frames of the doors and the windows are next to be confidered, and a new colour chofen, to diftinguifh them from the reft of the front. If the body of the houfe is painted yellow, or of a pale red, the angles and frames may be white or blue; if it is grey, they may be yellow or deep red, and in all cafes it will be a very eafy matter to find the moft fuitable colours. It is added, that the plafterers are equal to painting the fronts of houfes in a common way; but when builders or proprietors wifh to have them decorated in a fuperior manner, they muft call in a painter, whofe bufinefs it is to do it. The writer afferts that thefe paintings in frefco are more lively and more brilliant than any other; becaufe the colours are not deadened by fize or oil, which do not enter into their compofition; their effect is furprifing, and may be had at a little expence. And in concluding, it is remarked that the plafter proper to ferve as a ground for frefco painting or colouring, is made of one part lime and three parts clean, fharp, wafhed fand; alfo that this fort of painting has lately been executed with great fuccefs at Woburn Abbey, and fome other places in this country. It is not very ufual, it is obferved, to flake the lime in this country fo long before it is wanted; but it is an excellent practice, efpecially if it be wood-burnt.

In fhort, this method of building feems, from its cheapnefs and durability, and the readinefs with which it is executed, to deferve the attention of the proprietors of lands in this kingdom, as the means of raifing comfortable houfes for their labourers and cottagers, which, from the increafed prices of the ufual forts of building materials, are now become ferioufly expenfive in providing.

Some different kinds of buildings of thefe earthy materials may be feen at Woburn Abbey, the feat of the duke of Bedford, and in fome other places.

There are other neat buildings of the cottage kind, formed and raifed in this way, which may be feen in *Plate* XXII. in the fecond volume of the Farmer's Dictionary, under the head *Pifé Cottages*, with different elevations, ground plans, &c.

Others likewife built with the common forts of materials, but which may be raifed equally well and conveniently in pifé work, are reprefented at *figs.* 1, 4, and 7, in *Plate* VII. on *Agriculture*, under the title of *Ornamental Cottages*, in which *figs.* 2, 5, and 8, fhew the ground plans, and *figs.* 3, 6, and 9, thofe of the upper rooms. Thefe kinds of cottages would have an extremely neat and ornamental appearance when erected in the latter of thefe methods, about the entrances of parks and other kinds of pleafure grounds, as well as near any large country refidences, and at the fame time be built at an eafy expence.

PISEK, in *Geography*, a town of Bohemia, in the circle of Prachotitz, on the Watawa; 20 miles N. of Prachotitz. N. lat. 49° 22′. E. long. 14° 36′.

PISISTRATI Insulæ, three iflands on the coaft of Ionia, near Ephefus, called by Pliny Anthinæ, Myonnefos, and Diarrheufa.

PISISTRATUS, in *Biography*, an eminent Athenian citizen, was of noble defcent, which he derived from Codrus, the laft king of Athens, and inherited a large property from his father Hippocrates. He poffeffed the natural advantages of a commanding perfon, a ready elocution, and an uncommon capacity, which he improved with the utmoft diligence. Entering into public life, he promoted, by his eloquence, the endeavours of Solon to roufing the Athenians to the recovery of Salamis, and he accompanied that legiflator in the fuccefsful expedition for the purpofe. Naturally ambitious, he ingratiated himfelf with the lower claffes of citizens by the moft winning affability, and boundlefs

lefs liberality. He relieved their neceffities, fet open his gardens, and in all his difcourfes he was the advocate of political equality, and the democratic conftitution. Solon and others faw through the artifice of his conduct. Pififtratus one day haftily appeared in the market-place, bleeding from fome flight wounds which he had inflicted on himfelf, and loudly implored the protection of his fellow-citizens from pretended enemies, who were, he faid, purfuing his life, on account of his attachment to the democracy. From this time he obtained a guard to attend his perfon for his fecurity. This guard he foon employed to feize the citadel. He difarmed the multitude, and was now the undoubted mafter of Athens, while Solon, who had refifted his tyranny in vain, departed from his enflaved country. This event occurred B.C. 560. Though Pififtratus juftly incurred the charge of tyranny by the mode which he adopted to acquire his power, he by no means ufed that power in an offenfive way. On the contrary, it is thought, that very few lawful fovereigns ever conducted themfelves with greater moderation, or with more regard to the beft interefts of his countrymen. He did not in the leaft attempt to abrogate the wife laws of Solon, but invefted them with additional authority, and he always expreffed great veneration for the legiflator, whom he intreated, but in vain, to return to Athens. His fupremacy, however, was not as yet well fecured, and attempts were made by Megacles to overthrow his power. He fucceeded, and Pififtratus was obliged, in his turn, to become an exile, while his property was put up to public fale. Afterwards Megacles permitted him to return, on condition that he would marry his daughter, to which Pififtratus readily acceded, though he refufed to live with her, which fo far exafperated the father-in-law, that to avoid his vengeance he retired to Eretria. He there occupied himfelf in preparations for the recovery of his authority by force, which he effected in the eleventh year of his fecond exile. From this time he continued to govern with the fame lenity; but in order to weaken the popular party, he obliged many of the idle inhabitants to leave the city and engage in the cultivation of the furrounding diftrict: and by exacting the tenth of every man's income and produce, he augmented the public revenues, which he expended on magnificent buildings. He alfo ftudied to foften the minds of the Athenians by the encouragement of literature. He founded a public library, and made a collection of the poems of Homer, which were at that time fcattered in detached parts throughout Greece, and digefted them into the order which they have fince preferved. Senfible of the odium attaching to a tyranny, he was careful to mafk his power under the demeanour of a citizen, and in this way he exercifed the fovereignty during the remainder of his life, regarded rather as the father than the oppreffor of his country, which fcarcely ever enjoyed a longer period of quiet and profperity. He died in the year 527 B.C., leaving his fons, Hippias and Hipparchus, the heirs of his power. Univer. Hift.

PISKOI, in *Geography*, a town of Ruffia, in the government of Archangel, on the river Mezen; 188 miles E. of Archangel.

PISMIRE, in *Zoology*. See ANT.

PISO, L. CALPURNIUS, in *Biography*, furnamed *Frugi*, a Roman of a diftinguifhed patrician family, called the Calpurnian, according to Cicero; though in another paffage he reprefents him as the fon of a tribune. The epithet Frugi is faid to have been given him on the following occafion. When conful in the year 183 B.C., he went into Sicily in order to fupprefs a mutiny among the flaves, and after the bufinefs was effected, beftowing commendations from the tribunal on thofe who had chiefly contributed to the fuccefs, he awarded to his own fon the prize of a golden crown of three pounds weight, faying, at the fame time, that he meant to leave him the gold as a legacy, fo that he fhould receive the honour from his generals, and the reward from his father. For this inftance of frugality of the public money, the appellation of Frugi was beftowed upon him. In proof of the exactnefs of the principles of juftice by which he was governed, we have the following anecdote. He had always oppofed the law for the gratuitous diftribution of corn, but when it had been carried by C. Gracchus he came to demand his portion. Gracchus perceiving him ftanding in the crowd, afked him how he could be fo inconfiftent as to receive corn by virtue of the law which he had oppofed. To this he replied, "It was againft my will that you fhould have the diftribution of my property, but if it muft be fo, I will claim my fhare of it." Pifo was afterwards cenfor with Metellus Balearicus. He pleaded caufes, and was a promoter or oppofer of feveral laws. He left behind him various orations, and was the author of "Hiftorical Annals," which, though written in the meagre fimplicity of the times, were reckoned of good authority.

PISO, in *Commerce*, a weight ufed on the coaft of Guinea. A feron is $1\frac{1}{2}$ pifo, and a pifo is fubdivided into $1\frac{1}{3}$ quintos, 2 agiragues, or 4 media-tablas.

PISOGNE, in *Geography*, a town of Italy, in the department of the Benaco; 20 miles N.N.W. of Brefcia.

PISOLITE, in *Mineralogy*, a flaty artificial calcareous ftone of a grey colour, arifing from calx of iron. See LIME-*Stone*.

PISONIA, in *Botany*, received that appellation from Father Plumier, in memory of William Pifo, a phyfician of Leyden, the companion of Marcgraf, but whether his mafter or fervant remains in difpute. (See MARCGRAVIA.) Pifo furvived Marcgraf, but of the time of his death, or of his age, we find no account.—Plum. Gen. 7. t. 11. Linn. Gen. 551. Schreb. 739. Willd. Sp. Pl. v. 2. 283. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 333. Brown Prodr. Nov. Holl. v. 1. 422. Juff. 91. Lamarck Illuftr. t. 861. Gærtn. t. 76.—Clafs and order, *Polygamia Dioecia*, Linn. rather *Heptandria Monogynia*. Nat. Ord. *Aggregatæ*, Linn. *Nyctagines*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-fhaped; its limb in five acute, equal, fpreading, folded fegments, permanent. *Cor.* none. *Stam.* Filaments more numerous than the fegments of the calyx, ufually from fix to ten, prominent, awl-fhaped; anthers roundifh, two-lobed. *Pift.* Germen fuperior, oblong; ftyle fimple, cylindrical, longer than the calyx; ftigma cloven. *Peric.* Capfule oval, of one cell, without valves, clothed with the permanent pentagonal tube of the calyx. *Seed* folitary, fmooth, oblong.

Eff. Ch. Calyx bell-fhaped, five-cleft, plaited. Corolla none. Capfule of one cell, without valves, clothed by the angular calyx. Seed folitary.

Obf. The ftamens on one plant, and the piftils on another, are more or lefs imperfect, fo that the genus is, in effect, dioecious, or at leaft polygamous; but it is one of thofe which, having no other difference of ftructure in their flowers, but, on the contrary, the rudiments at leaft of both organs prefent in every flower, are beft claffed by the number of their ftamens. In this latter refpect however *Pifonia* is uncertain, like its relations *Mirabilis*, *Valeriana*, and *Boerhavia*.

1. P. *aculeata*. Prickly Pifonia, or Fingrigo. Linn. Sp. Pl. 1511. Ait. n. 1. Plum. Ic. t. 227. f. 1. (Paliuro

liuro affinis arbor ſpinoſa, &c.; Sloane Jam. v. 2. 25. t. 167.)—Spines axillary, horizontal. Leaves ovate, acute at each end, ſmooth. Calyx of the fruit prickly.—Native of the Weſt Indies. A tree whoſe *trunk* is as thick as a man's thigh, eight or nine feet high, with weak drooping ſpinous branches. *Leaves* nearly oppoſite, ſtalked, ſimple, entire, ſmooth, pointed, two or three inches long and one broad, deciduous. *Flowers* appearing before the leaves in denſe downy *panicles*, about the ends of the branches, yellowiſh-green, bracteated, ſmall, ſmelling like elder. *Fruit* club-ſhaped, its angles beſet with numerous, regular, obtuſe, prickles, the *panicle* being enlarged and divaricated.

2. P. *ſubcordata*. Heart-ſhaped Fingrigo, or Loblolly-tree. Swartz Ind. Occ. v. 2. 641. Willd. n. 2.—Spines none. Leaves roundiſh-heart-ſhaped. Calyx of the fruit dry, its angles prickly in the upper part.—Native of Antigua, St. Kitt's, &c. A tree, with unarmed, ſmooth, brittle *branches*. The wood is of little uſe, whence, according to Swartz, it is called *loblolly*, an appellation given in the Weſt Indies, to a number of trees whoſe wood is good for nothing. *Leaves* ſtalked, oppoſite, ſmooth, turning black in drying. *Cymes* axillary, ſtalked. *Flowers* minute, greeniſh, polygamous. *Stamens* ſeven.

3. P. *nigricans*. Black-berried Fingrigo. Swartz Ind. Occ. v. 2. 643. Willd. n. 3. Ait. n. 2. (P. inermis; Jacq. Amer. 275.)—Spines none. Leaves ovate, pointed, ſmooth. Flowers cymoſe, erect. Calyx of the fruit pulpy, ſmooth.—Native of mountainous woods in Jamaica and Hiſpaniola. *Swartz*. Jacquin ſays it is frequent about Carthagena. A ſmall *tree*, or *ſhrub*, ten or twelve feet high, with ſmooth *branches*, deſtitute of thorns. *Leaves* ſtalked, oppoſite, ſmooth on both ſides. *Cymes* ſtalked, terminal and axillary, of many ſmall yellowiſh-green upright *flowers*, with two or three minute acute *bracteas* at the baſe of each. *Fruit* oval, ſmooth, black, the tube of the *calyx* which clothes it becoming pulpy as the *ſeed* ripens, but there are no prickles upon it.

4. P. *coccinea*. Scarlet-berried Fingrigo. Swartz Ind. Occ. v. 2. 645. Willd. n. 4.—Spines none. Leaves elliptic-lanceolate, ſmooth. Panicles terminal, looſe. Flowers drooping. Calyx of the fruit pulpy, ſmooth.—Native of buſhy places in Hiſpaniola, flowering in May. *Sw.* A *ſhrub*, or ſmall *tree*, with ſmooth, round, unarmed *branches*. *Leaves* ſcattered or oppoſite, on longiſh ſlender ſtalks, and tapering at each end; paler beneath. *Flowers* whitiſh-brown, ſmall, drooping, with three linear *bracteas* at their baſe. *Stamens* ſeven, rarely eight or ten. *Fruit* oblong, ſmooth, pulpy, ſcarlet. We have an authentic ſpecimen of this from Dr. Swartz. If we are right in a ſpecimen in the herbarium of the younger Linnæus, which we preſume to be the *nigricans*, that ſpecies differs from *coccinea* in having much ſhorter and broader *footſtalks*, as well as far more numerous and ſtraight tranſverſe veins to the *leaves*, which latter are obovate, rather than ovate. The *fruit* is ſmooth, oblong, in a long-ſtalked ſpreading *panicle*. Probably the ſtalk is elongated after flowering, as Swartz deſcribes it ſhorter, in that ſtate, than the leaves.

5. P. *mitis*. Small-thorned Piſonia. Linn. Sp. Pl. 1511. Willd. n. 5. (P. inermis; Swartz Obſ. 393. Katukava walli; Rheede Hort. Mal. v. 7. 13. t. 17, on the authority of Linnæus.)—Spines axillary, curved. Leaves ovate, downy. Calyx of the fruit downy, without prickles. Native of the Eaſt Indies. *Koenig*. This has the habit of the firſt ſpecies, but the *ſpines* are fewer, ſmaller, and curved. *Leaves* oppoſite or aggregate, alternate on the young ſhoots, ovate, or elliptic-lanceolate, with a blunt point, obſcurely veined, clothed, more or leſs denſely, with ſhort ruſty down. *Footſtalks* downy, a quarter the length of the leaves. *Flower-ſtalks* axillary, often two together, longer than the leaves, downy, with oppoſite branches all towards their ends, bearing denſe tufts of ſmall downy *flowers*, with ovate downy *bracteas*. *Stamens* ſeven. *Panicle* of the fruit more lax and ſpreading. *Fruit* obovate, clothed with the downy tube of the *calyx*, deſtitute of prickles. As we unfortunately have not acceſs at preſent to the ſeven latter volumes of the Hortus Malabaricus, we cannot examine into Rheede's ſynonym, but our ſpecimens having *ſpines*, one part of the difficulty, which has ſo much embarraſſed authors, is removed. The Linnæan herbarium has no marked ſpecimen; but the ſpecies ſeems to us perfectly clear in its characters and hiſtory. Poiret, in Lamarck, has confounded it, under the faulty name of *inermis*, with the *nigricans* of Swartz.

6. P. *grandis*. Superb Piſonia. Brown Prodr. Nov. Holl. v. 1. 422. Ait. n. 3.—"Stem arboreous. Leaves oblong, pointed, ſmooth. Cymes compound. Flowers polygamous. Stamens from ſeven to nine. Calyx of the fruit prickly."—Found by Mr. Brown in the tropical part of New Holland, and brought in 1805 to Kew, where it is kept in the green-houſe, but has not yet bloſſomed. We have ſeen no ſpecimen.

7. P. *villoſa*. Broad-leaved Piſonia. Poiret in Lamarck Dict. v. 5. 347?—Leaves ovate, obtuſe, ſomewhat downy. Panicles denſe, repeatedly branched, downy. Calyx very ſlightly divided.—Native of the iſland of Mauritius. Our ſpecimen came from Thouin's herbarium. The bark of the *branch* is ſmooth, without thorns. *Leaves* two or three inches long, and half as broad, ſtalked, ovate, obtuſe, wavy, thinly covered with fine ſhort pubeſcence, which perhaps diſappears at a more advanced period. *Flowers* very numerous, in denſe, round, ſtalked, downy panicles, whoſe copious ſubdiviſions are alternate. *Calyx* abrupt, club-ſhaped, downy. *Anthers* large, reddiſh. We have ſeen no *fruit*. Our only doubt is whether Poiret's plant may not be our *mitis*. We have therefore deſcribed our own ſpecimen, without borrowing any thing from him, and to this, in either caſe, the name of *villoſa* may remain. Our's has all the appearance of being one of Sonnerat's ſpecimens. As it is the young extremity of a *branch*, the *ſpines* may well be wanting.

The P. *ſubovata*, Poiret n. 4, is an accidental error for *ſubcordata* of Swartz.

The beautiful BUGINVILLÆA of Commerſon, ſee that article, is very nearly allied to *Piſonia*. Its curiouſly twiſted limb of the *calyx*, in the ripening *fruit*, is not repreſented by Lamarck, though it may have ſome weight in the generic character.

PISONIA, in *Gardening*, contains plants of the exotic tree kind for the ſtove, of which the ſpecies cultivated is the prickly piſonia (P. aculeata.)

Method of Culture.—It is increaſed by ſeeds, which ſhould be ſown in pots filled with light rich earth, and plunged into a hot-bed of tanners' bark; and when the plants come up, they ſhould be tranſplanted into ſeparate pots, and plunged into the hot-bed again, where they may remain till autumn, when they ſhould be removed into the ſtove, and plunged into the bark-bed, and treated in the ſame manner as has been directed for ſeveral tender plants of the ſame country; in hot weather giving them plenty of water, but in winter more ſparingly.

They are too tender to thrive in the open air of this country at any ſeaſon of the year, they ſhould, therefore, be conſtantly kept in the ſtove. They retain their leaves moſt part of the year in this climate.

The

The plants afford variety in ftove collections of exotic plants.

PISONOS, in *Ancient Geography*, a town of Afia, in Leffer Armenia, on the route from Sebafte to Cocufon, between Ad Prætorium and Melitene, according to the Itinerary of Antonine.

PISRAH, in *Geography*, a town of Hindooftan, in Bahar; 58 miles S.S.W. of Patna.

PISSA, a town of Pruffian Lithuania; four miles S. of Stalluponen.—Alfo, a river of Pruffia, which runs into the Pregel, near Infter.

PISSANIZENA, a town of Pruffia, in Natangen; 10 miles S. of Marggrahowa.

PISSASPHALTUM, or Pissasphaltus, πισσασφαλτος, compounded of πισσα, *pitch*, and ασφαλτος, *bitumen*, in *Natural Hiftory*, denotes a native, folid bitumen, found in the Ceraunian mountains of Apollonia: of an intermediate nature between pitch and afphaltum. Its characters are thefe: the piffafphalta are fluid mineral bodies, of a fomewhat thick confiftence, dufky, and opaque; of a ftrong fmell, and readily inflammable, but leaving a refiduum of greyifh afhes after burning.

There are three known fpecies of this genus. 1. A thinner blackifh kind, called *oleum terræ*, and *petrol*. 2. A thicker black one, called *piffelæum Indicum*, or *Barbadoes tar*. And, 3. A black and vifcous one, called fimply *piffafphaltum* in the fhops. See Bitumen.

Piffafphaltum is as tough and vifcous as bird-lime, and of the fame confiftence when old. It very much refembles the common black pitch, when foftened a little by heat; and has been generally thought to have fomething of the fmell of that fubftance; but this feems to have arifen from its being too frequently adulterated by mixing pitch with it, and the true genuine fubftance has no other fmell than the rank one of all the bitumens, which fomewhat refembles that of oil of amber. It is produced in feveral parts of the world, and there are large quantities of it in Germany, in Perfia, and in France. It yields a limpid oil by diftillation, which very much refembles the native petroleum, and is too often fold with us under this name, being annually imported in large quantities from thofe parts of Germany where it is manufactured, and having itfelf no particular name in the fhops of our druggifts.

Piffafphaltum was much recommended by the ancients for external ufe, as an emollient, maturant, and digeftive: with this intention it was ufed in cataplafms, for ripening all forts of tumours, and againft the fciatica and other pains of the limbs. They alfo had recourfe to it for ftrengthening the limbs, after the reduction of diflocations. It is little ufed at prefent, the petroleum being thought very proper to fupply its place.

Pissasphaltum is alfo a name given to a factitious fubftance, compounded of pitch and afphaltus, or the true bitumen Judaicum.

The coarfenefs of this, the black colour, and the fetidnefs of the fmell, diftinguifh it from the true afphaltum.

Pissasphaltum is alfo ufed, by fome writers, to denote the Jewifh pitch, or fimple afphaltum.

PISSELÆUM, πισσελαιον, *oleum Picinum*, or oil of pitch, an obfolete medicament compounded of oil and pitch.

Pisselæum *Indicum*, among *Modern Writers*, denotes a bituminous fubftance brought from the Weft Indies, popularly called *Barbadoes tar*.

It is a heavy, thick, and dufky-looking mineral fluid, of the colour and confiftence of common treacle, and of a very opaque hue; it is of a difagreeable fmell, faintly approaching to that of oil of amber, and is very inflammable. It is found trickling down the fides of the mountains at the back of feveral of our plantations in America, and is in great efteem there for coughs and diforders of the lungs. We meet with very little in England that is genuine, feveral different fophiftications of it being in common ufe, even upon the fpot. (See Bitumen.) It has a ftrong fmell not unlike the common tar, and is not very pleafant to fight or tafte. It is accounted a good balfamic, and where the ftomach can difpenfe with it, will do great fervice in many diforders of the breaft, which has alfo been experienced of common tar.

PISSER, in *Geography*, a mountain of the county of Tyrol; four miles S.E. of Landeck.

PISSEROS, the name of an ointment greatly recommended by Hippocrates in many cafes, as in burns, frefh wounds, &c. It was made of oil of rofes, bees-wax, and pitch, proportioned fo as to give the whole a foft confiftence. It was of the nature of our modern black bafilicon, and found a good ointment in many cafes.

PISSINUM. Pliny fays it was cuftomary for the ancients to hold fleeces of wool over the fteam of boiling tar, and fqueeze the moifture from them, which watery fubftance was called *piffinum*.

Ray will have this to be the fame with the piffelæum of the ancients; but Hardouin, in his notes on Pliny, thinks the piffelæum to have been produced from the cones of cedars. What ufe they made of thefe liquors anciently, is not known; but it may be prefumed they were ufed in medicine, though at prefent it does not appear they are ufed at all.

PISSITES, a name given by the ancients to a wine impregnated with the virtues of liquid pitch or tar. To prepare it, the tar was ordered to be wafhed in fea-water or brine, and afterwards in frefh water many times; and after a tedious preparation of this kind, two ounces of it were ordered to be put to eight gallons of muft, which is to be fuffered to work together, and the clear liquor to be bottled off.

This was accounted a warm wine, very affiftant to concoction, and of an abfterfive faculty, and a good pectoral: on thefe accounts it was given in diforders of the breaft, and in obftructions of the liver, fpleen, and uterus, if not attended with a fever; and was a common medicine in coughs and afthmas of all kinds.

PISSOCEROS, a name given by the old naturalifts to a fubftance found very frequently in the hives of bees, and confifting of a mixture of propolis and wax. The ancients were well acquainted with the ufe of this fubftance, which was ufed for ftopping up the cracks and chinks in the hives: they mention, indeed, three forts of matter ufed by the bees for this purpofe; the metys, the piffoceros, and the propolis; but later authors call them all by the general term propolis, the piffoceros and metys being only the fame fubftance, mixed with wax in different proportions. This propolis is a refinous fubftance, of a foft and vifcous confiftence, collected from the beds of the poplar and other trees.

PISSOS, in *Geography*, a town of France, in the department of the Landes, and chief place of a canton, in the diftrict of Mont-de-Marfan; 27 miles N.W. of Tartas. The place contains 1338, and the canton 4572 inhabitants, on a territory of 482½ kiliometres, in feven communes.

PISSOSIS, a word ufed by the old writers on medicine for the depraved appetite of young women about the firft eruption of the menfes, and of fome women with child.

PISS-POT Bay, in *Geography*, a bay in the ftraits of Magellan. S. lat. 53° 14′. W. long. 75° 12′.

PISTACHIA-Nut, in *Botany*, *Gardening*, &c., a well known fort of nut. See Pistacia.

Pistachia, or *Piftach-nut*, a fruit brought from feveral

 parts

parts of Asia, chiefly from Aleppo and Persia. When wrapt in all its coats, it is of the size of a green almond; but when stript of all but its shell, it resembles a small nut. The kernel is red without, and green within; its taste is very agreeable.

The word is formed from the Latin *pistacium*, of the Greek πιστακιον, whence, according to Menage, the city Psittacium took its name.

The tree that produces it is a kind of turpentine-tree. See Pistacia.

The nuts are to be chosen new, heavy, and full; as to those that are broken, such as have kept their colours best are to be preferred; for nothing depends upon the size.

Pistachias have been reckoned aperitive, and proper to give vigour; and used in emulsions, &c. in phthisical and nephritical cases. They also enter several ragouts, and are comfited, made into conserves, &c. There is likewise a kind of false pistachia, brought from the Caribbee islands, which some confound with the real ones, though very different, both with regard to the plants that produce them, and their quality. The spurious pistachia plant does not rise above a foot high; nor does the fruit grow on the branches, but is found in pods. The pod sometimes only contains a single nut, which resembles an olive; but usually several; and in that case they are irregular. The substance is white, compact, and heavy.

This fruit is rarely eat raw, because of the ill effects it produces; it is usually roasted or comfited; it is used in ragouts, and to make ratifias.

Pistachia-*Tree, Black Virginian*, a species of the *hamamelis*; which see.

PISTACIA, in *Botany*, πιστακια of Dioscorides, a word of doubtful origin. Athenæus attributes it to the Syrians. Forskall gives *fostuk* as the Arabic name of the *Lentiscus*, and Olaus Celsius of the *Pistacia*; hence De Theis supposes πιστακια a corruption of that word; but surely it is hazarding enough to presume them of one common origin. Rauwolf's *fistuc* indeed comes much nearer.—Linn. Gen. 518. Schreb. 683. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 5. 381. Lamarck Illustr. t. 811. (Terebinthus; Tourn. t. 345. Juss. 371.)—Class and order, *Dioecia Pentandria*. Nat. Ord. *Amentaceæ*, Linn. *Terebintaceæ*, Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf, in five deep equal segments. *Cor.* none. *Stam.* Filaments five, capillary, very short, spreading; anthers large, oblong, quadrangular, obtuse, of two cells bursting lengthwise, spreading.

Female, on a separate plant, *Cal.* Perianth of one leaf, inferior, in three deep equal segments, deciduous. *Cor.* none. *Pist.* Germen superior, roundish, somewhat triangular; styles three, erect; stigmas spreading, obovate, thickish, hispid, undivided. *Peric.* Drupa dry, coriaceous, ovate. *Seed.* Nut ovate, smooth.

Eff. Ch. Male, Calyx five-cleft. Corolla none. Female, Calyx three-cleft. Corolla none. Styles three. Drupa dry. Nut single-seeded.

Obs. Linnæus considers the male flowers as constituting a catkin. Jussieu discretely terms it *racemus amentaceus*. The inflorescence is actually a panicle, with a bractea under each of its subdivisions, in both sexes; which is proved by the presence of a true perianth to each flower in each.

1. P. *officinarum*. Pistachia-nut Tree. Ait. n. 1. (Pistacia; Matth. Valgr. v. 1. 248. Bauh. Hist. v. 1. par. 1. 275. Ger. em. 1436. Pistachi, fistuc of the Arabians; Rauw. It. 72. t. 9. Terebinthus indica Theophrasti, Pistacia Dioscoridis; Tourn. Inst. 580. Duham. Arb. v. 2. 306. t. 88.)—Leaves simple, ternate, or pinnate; leaflets oval. Fruit ovate, pointed.—Native of Syria, and other countries in the Levant. Matthiolus says the Venetians usually imported the nuts from Syria. The tree has often been raised in this country, and as often lost. It is marked as hardy in Hort. Kew. flowering in April and May. We have had no opportunity of seeing more than a dried specimen, without flowers. The young *leaves* are ternate, the more advanced ones pinnate; the leaflets elliptical or ovate, pointed, slightly wavy, entire, smooth, except a fine, chiefly marginal, pubescence when young. Their midrib sends off several parallel transverse veins, connected by fine reticulations. *Fruit* panicled, about an inch long, ovate, with an oblique point, reddish, well known, for the sake of its nut, at our tables. The green internal hue of the kernel is remarkable. Linnæus's history of this plant is so extremely confused, that we have judged it best to follow Mr. Aiton in its name, rejecting the synonym of Boccone, Mus. v. 2. 139. t. 93, which is certainly a female, not a male, plant, though called so by the author, after the old Bauhinian fashion; and it appears to us rather to belong to the next species. The figures we have cited mostly represent three pair of leaflets, with an odd one; the Hort. Kew. describes two pair at the utmost; yet these figures must be authentic. Our plant must be what Linnæus meant by his *P. vera*, but he was imposed upon by a full-grown specimen of *P. Terebinthus*, whence his specific character of *vera* is taken. He was still more deceived by Koehler, with a branch of *Fraxinus Ornus* for *P. narbonensis*. The latter species therefore is best omitted, whatever its synonyms may belong to. We have not materials to arrange all these with any certainty.

2. P. *reticulata*. Net-leaved Pistachia Tree. Willd. Sp. Pl. v. 4. 751. Ait. n. 2. (P. trifolia; Linn. Sp. Pl. 1454. Pistacium mas ficulum, folio nigricante; Bocc. Mus. v. 2. 139. t. 93? Terebinthus indica major, fructu rotundo; Bauh. Hist. v. 1. par. 1. 278.)—Leaves ternate and pinnate; leaflets roundish, abrupt, somewhat pointed; tapering at the base; strongly reticulated with prominent veins. Fruit roundish-oval, obtuse.—Native of the Levant. Cultivated by Miller, as well as in the French gardens. It is generally taken for the *trifolia* of Linnæus, and perhaps ought to retain that name, but as the *leaves* are often pinnate, which Linnæus himself remarks, and as they mostly are so in our specimen, we submit to the above change. There seems never to be more than two pair of leaflets, and an odd one; they are all large, coriaceous, broad, rounded, and obtuse; their veins remarkably and strongly reticulated; their base more or less contracted, elongated, or wedge-shaped. When young they are downy at the margin, and elsewhere, like the foregoing. Bauhin represents the *fruit* as more rounded and obtuse than the common Pistachia, but equally good. His *leaves* however are much too pointed for our plant, and agree far better with the former; while, on the other hand, the *leaves* in Rauwolf's cut, cited for *P. officinarum*, to which his *fruit* belongs, come nearer to the *reticulata*. After all, these plants may possibly be but varieties, and we are much inclined to come to that conclusion. The following are more intelligible, and better defined by authors.

3. P. *Terebinthus*. Common Turpentine Tree. Linn. Sp. Pl. 1455. Ait. n. 3. Woodv. Med. Bot. t. 153. (Terebinthus; Matth. Valgr. v. 1. 101. Ger. Em. 1433. Bauh. Hist. v. 1. par. 1. 279. T. vulgaris; Tourn. Inst. 579. Duham. Arb. v. 2. 306. t. 87.)—Leaves pinnate; leaflets numerous, ovato-lanceolate, acute, recurved. Flowers panicled. Segments of the calyx awl-shaped, longer than the stamens.—Native of the south of Europe and north of Africa. Long known in our gardens. There is a fine female tree at Chelsea garden, near the gate, which, for

for want of the male bloſſoms, can never perfect its fruit. The habit of this ſpecies is like the two foregoing, the *trunk* and *branches* rugged, and bent in all directions. *Leaves* of three to five pair of ovate-oblong entire ſmooth leaflets, with an odd one, all ſomewhat curved backwards. They are, in our climate at leaſt, deciduous, and appear by Dr. Sibthorp's drawings to be ſo in Greece. Their red hue, when young, is beautiful. *Flowers* in large, very compound, *panicles*. *Anthers* dull yellow. *Stigmas* crimſon. *Fruit* ſcarcely bigger than a large pea, globular, a little compreſſed, reticulated. Galls of the ſame ſhape are found on the leaves, and very large oblong ones, like legumes, are often produced from the young branches, as the old figures repreſent. The reſin of this tree is the Chian or Cyprus Turpentine, generally preferred, for medical uſe, to what is obtained from the Fir tribe; but it is ſcarcely to be had without adulteration.

4. P. *Lentiſcus*. Maſtick Tree. Linn. Sp. Pl. 1455. Ait. n. 4. Woodv. Med. Bot. t. 152. (Lentiſcus; Matth. Valgr. 1. 99. Ger. Em. 1432. Bauh. Hiſt. v. 1. par. 1. 283. L. vulgaris; Tourn. Inſt. 580. Duham. Arb. v. 1. 354. t. 136.)—Leaves abruptly pinnate; leaflets ovato-lanceolate. Flowers racemoſe. Segments of the calyx ovate, ſhorter than the ſtamens.—Native of the ſouth of Europe. Leſs hardy than the laſt, and requiring the ſhelter of a greenhouſe in our climate, being evergreen. In Italy it is very common, flowering about April; as well as in the Levant, where its reſin, called maſtick, is a well-known article of luxury, and different varieties of this ſhrub are conſequently cultivated with care. It differs from every other known *Piſtacia*, in having no odd leaflet, whence Tournefort made it a diſtinct genus; as well as in its ſimply racemoſe infloreſcence, and the ſhortneſs of the *calyx*; but there is nothing like a reaſonable generic diſtinction, either in fructification or habit. The wood, called *lignum lentiſchinum*, has been ſuppoſed to poſſeſs ſome medical virtues, but its chief fame at preſent is in Portugal, where it ſerves for toothpicks. Theſe are rather more neat than if made of deal.

P. *oleoſa*. Lour. Cochinch. 615, is enveloped in too much uncertainty to be received without examination of ſpecimens.

Pistacia, in *Gardening*, contains plants of the exotic, deciduous, tree and ſhrubby evergreen kinds, of which the ſpecies cultivated are the true piſtacia tree (P. vera); the common turpentine tree (P. terebinthus); and the maſtic tree (P. lentiſcus.)

With reſpect to the ſecond ſort, it may be remarked, that the Cyprus or Chian turpentine, which it furniſhes, is procured by wounding the bark of the trunk in ſeveral places, during the month of July, leaving a ſpace of about three inches between the wounds; from theſe the turpentine is received on ſtones, upon which it becomes ſo much condenſed by the coldneſs of the night, as to admit of being ſcraped off with a knife, which is always done before ſun-riſe; in order to free it from all extraneous admixture, it is again liquefied by the ſun's heat, and paſſed through a ſtrainer: it is then fit for uſe.

Of the third ſort, there is a variety which riſes to the ſame height as the preceding; but differs from it in having a pair or two of leaflets more to each leaf, much narrower, and of a paler colour. It is a native of the country about Marſeilles, &c.

Method of Culture.—The firſt is capable of being increaſed by the ſeeds or nuts procured from abroad, and planted in the ſpring, in pots filled with light kitchen-garden earth, plunging them in a moderate hot-bed; when the plants appear, a large ſhare of air ſhould be admitted to them, to prevent their drawing up weak; and by degrees they ſhould be hardened to bear the open air, to which they may be expoſed from the beginning of June till autumn, when they ſhould be placed under a hot-bed frame to ſcreen them from the froſt in winter; as while young, they are too tender to live through the winter in this climate without protection, but ſhould always be expoſed to the air in mild weather; they ſhed their leaves in autumn, and therefore ſhould not have much wet in winter. In the ſpring, before the plants begin to ſhoot, they muſt be removed each into a ſeparate ſmall pot; and be plunged into a very moderate hot-bed, to forward their putting out new roots. As ſoon as they begin to ſhoot, they muſt be gradually hardened, and placed abroad again.

Theſe plants may be kept in pots three or four years, till they have got ſtrength, during which time they ſhould be ſheltered in winter; and afterwards be turned out of the pots, and planted in the full ground, ſome againſt high walls to a warm aſpect, and others in a ſheltered ſituation, where they bear the cold of our ordinary winters very well, but in ſevere froſts are often liable to be deſtroyed. The trees flower and produce fruit, but the ſummers are ſeldom warm enough to ripen the nuts.

The third ſort is alſo capable of being increaſed by laying down the young branches, which, if properly managed, put out roots in one year, and may be cut off from the old plants, and be planted out into ſeparate ſmall pots. Theſe muſt be ſheltered in winter, and in ſummer placed abroad in a ſheltered ſituation, and treated in the ſame way as other hardy kinds of green-houſe plants.

When raiſed from ſeeds they ſhould be taken from trees growing in the neighbourhood of the male plants, as otherwiſe they will not grow. When theſe plants have obtained ſtrength, ſome of them may be turned out of the pots, and planted againſt warm walls; where, if their branches are trained againſt them, they endure ordinary winters very well, and with a little ſhelter in ſevere winters may be preſerved with ſafety.

They are curious and ornamental in different ſituations.

PISTAKETI, in *Geography*, a town of the principality of Georgia, in the province of Carduel; 40 miles S.S.W. of Teflis.

PISTANA, in *Botany*, a name by which ſome authors have called the *ſagittaria aquatica*, or water arrow-head.

PISTATIO, among *Pharmaceutic Writers*, a word uſed to expreſs that preparation of ſimples which conſiſts in covering them with, or including them in, a paſte, and ſending them to a baker's oven till tender throughout. Squills are ſometimes prepared thus.

PISTAZITE, in *Mineralogy*, named alſo by ſome writers Acanticone, Arandalite, and Thallite, is a ſpecies of the flint genus: of a piſtachio-green, which paſſes into olive-green and blackiſh-green. It is found in a maſſive and cryſtallized ſtate, under different forms: 1. In ſix-ſided priſms, in which the lateral edges are ſometimes truncated and ſometimes bevelled; and the terminal edges and angles are truncated. 2. In very oblique four-ſided priſms, which have a reed-like aſpect; ſometimes they are acuminated by four planes, and ſometimes bevelled on the extremities, and the bevelling planes are ſet on the obtuſe lateral edges. 3. In acicular cryſtals; internally it is ſhining; the fracture is foliated, ſometimes narrow and parallel. The fragments are ſometimes indeterminately angular, ſometimes wedge-ſhaped and ſplintery. It occurs in coarſe granular diſtinct concretions. It is tranſlucent, which, in the cryſtallized varieties, paſſes into tranſparent. It is hard, eaſily frangible, and not particularly heavy. It is found in beds in primitive mountains in Norway, Saxony, France, and Bavaria.

PISTE,

PISTE, in the *Manege*, the track or tread which a horfe makes upon the ground he goes over.

The word is French, and literally fignifies a *track*.

The pifte of a horfe may be either *fingle* or *double*.

If the rider make him go but an ordinary gallop, in a circle, or rather fquare, he will make but a fingle pifte: if he either make him gallop with his haunches in, or go terra a terra, he will make two piftes, one with the fore-part, another with the hind. And the fame if the rider make him paffage, or go fideways, either in a ftraight line, or upon a circle.

PISTEREEN, or PIASTRINE, in *Commerce*, the name given in the Weft Indies to the Spanifh pecetas. Piftereens are alfo called two-bit pieces; they pafs at Jamaica for 1*s*. 3*d*. currency, and are worth 10½*d*. fterling. Englifh fhillings and fixpences occafionally pafs here as piftereens and bits.

PISTIA, in *Botany*, fo named by Linnæus, from πιςης, *a channel* or *watering place*, becaufe it inhabits pools and rivers.—Linn. Gen. 467. Schreb. 455. Willd. Sp. Pl. v. 3. 690. Mart. Mill. Dict. v. 3. Juff. 69. Lamarck Illuftr. t. 733. (Kodda-pail; Plum. Gen. 30. t. 39.)—Clafs and order, *Gynandria Hexandria*, Linn. *Monadelphia Octandria*, Schreb. Willd. Nat. Ord. *Inundatæ*, Linn. *Hydrocharides*, Juff.

Gen. Ch. corrected by Schreber, *Cal.* none. *Cor.* of one petal, unequal, erect, permanent; tube fhort, clofely embracing the germen; limb roundifh, fomewhat heart-fhaped, dilated, pointed, undivided, contracted at each fide, in the middle, by a lateral plait directed inwards. *Stam.* Filament round, thick, obtufe, fpringing almoft perpendicularly from the centre of the limb of the corolla, and ftanding over the piftil, furrounded at the bafe by a membranous difk, and augmented at each fide below, with a dependent fringe, the breadth of the anthers; anthers fix to eight, globofe, ftanding in a row round the margin of the filament at its fummit. *Pift.* Germen fuperior, nearly ovate, twice as long as the tube of the corolla, attached to the back of the petal by a thickened longitudinal line, reaching to the origin of the filament; ftyle thick, erect, fhorter than the filament; ftigma obtufe, fomewhat peltate. *Peric.* Capfule ovate, compreffed, of one cell. *Seeds* numerous, oblong, depreffed, and marked with an umbilicated point at the fummit, horizontally inferted into the back of the capfule, where it is attached to the corolla.

1. P. *Stratiotes*. Linn. Sp. Pl. 1365. Jacq. Amer. 234. t. 148. (Kodda-pail; Rheede Malab. v. 11. 63. t. 32. Plantago aquatica; Rumph. Amboin. v. 6. 177. t. 74. Stratiotes; Alp. Ægypt. 106. t. 108, 109. Vefling. Ægypt. 44. t. 45.)—Native of Afia, Africa, and South America, in ftagnant waters. Rumphius fays it is found only in fuch as have a muddy bottom, though the plant floats entirely like a *Lemna*, fending down its long, ftraight, fimple, pubefcent *roots* deep into the water, but not fo far as the ground. The whole herb confifts of a number of broad wedge-fhaped obtufe *leaves*, fpreading in the form of a large rofe, without any ftem, of a coriaceous or rather fpongy texture, ribbed, glaucous, with a velvet-like furface; the innermoft more erect, convoluted, and downy. *Flowers* white, axillary. The plant is propagated by long lateral runners, each terminating in a bud.

PISTICCIO, in *Geography*, a town of Naples, in Bafilicata; 12 miles from Turfi.

PISTILLUM, in *Botany* and *Vegetable Phyfiology*, the piftil of a flower, is one of thofe effential parts of the fructification, neceffary to the production of feeds. It is either one or feveral, fituated in the centre of the flower, within the ftamens, if the latter be, as ufual, in the fame flower. When in a feparate one, the piftils are not always central. The idea of Linnæus, of their originating from the pith, and the ftamens from the wood, is refuted by anatomical obfervation, as well as by more correct phyfiological enquiries. Each piftil confifts properly of three parts; the *germen*, or rudiment of the young fruit or feed, which of courfe is effential; the *ftyle*, various in length and thicknefs, not always prefent, as it merely ferves to elevate the third part, the *ftigma*, which, though indifpenfably neceffary, is, in feveral cafes, feated immediately upon the germen. See FECUNDATION *of Plants*, GERMEN, and, hereafter, STIGMA and STYLUS, or STYLE.

Piftils are fometimes obliterated, though more generally transformed to petals, in double flowers, as well as the ftamens. In the double-bloffomed cherry the piftil is actually changed to a leaf. The ftyle in that cafe becomes dilated, ferrated, and affumes a deep green colour, turning to a perfect leaf, and the ftigma, without much vifible change, becomes the gland terminating the leaf, like what is found on the original and proper foliage. Some plants, which increafe plentifully by root, are fubject to have the piftils weakened and abortive, as in Mint, and *Lilium bulbiferum*; but they do not, in fuch cafes, undergo any transformation. Many whole genera have rudiments only of piftils in fome flowers, and of ftamens in others, as the *Rhodiola*; fuch plants being in effect either dioecious, or monoecious. Still more have, intermixed with perfect flowers, whofe male as well as female organs are complete, a greater or lefs number whofe ftamens only are perfect and effective, their piftils being imperfect, or entirely obliterated. Such is the nature of a great majority of tropical trees, which are therefore, in Linnæan language, polygamous, and ftrictly belong to the clafs *Polygamia*; but fo much difficulty attends a clofe adherence in practice to this principle, in confequence of accidental variations, that it is found beft to confider no plants as polygamous that have not a difference of ftructure in their feveral flowers. See POLYGAMIA.

PISTILS FIORD, in *Geography*, a bay on the N. coaft of Iceland.

PISTIS, in the *Materia Medica of the Ancients*, a name given to the gum bdellium, particularly to that kind of it which was brought from Arabia, and was of a fine yellowifh-white, and in fmall round drops, or lumps of a roundifh fhape, and firm confiftence.

PISTOCCHI, FRANCESE-ANTONIO, of Bologna, in *Biography*, one of the greateft ftage fingers of the feventeenth century, began to flourifh, both as a performer and compofer, about the year 1679. He was retained fome time at the court of the margrave of Brandenburg as maeftro di capella; but late in life, after eftablifhing a fchool of finging at Bologna, which was afterwards continued by his difciple Bernacchi, he retired to a monaftery, where he ended his days.

An oratorio of his compofition, which we were fo fortunate as to find in Italy, called "Maria Virgine Adolorata," has more merit of expreffion, and elegance of melody, than any vocal mufic of the fame century. There is no date to this compofition; but by the fimplicity of the ftyle it feems to have been produced about the end of the 17th century, at which time recitative, freed from formal clofes, and in poffeffion of all its true forms, was occafionally extremely pathetic and dramatic; and Piftocchi feems a more correct contrapuntift than the generality of opera fingers whom the demon of compofition feizes at a period of their lives, when it is too late to begin, and impoffible to purfue fuch ftudies effectually, without injuring the cheft, and neglecting the cultivation of the voice. This oratorio has neither overture nor chorus. The interlocutors are an angel, the Virgin Mary,

Mary, Mary Magdalen, and St. John. At the termination of this oratorio, which is truly pathetic and folemn, all the degrees of the diminution of found are ufed: as *piano, più piano, pianiffimo*, equivalent to the *diminuendo, calando*, and *fmorzando*, of the prefent times.

Piftocchi publifhed fix cantatas, with two duets, and two airs, one to French, and one to Italian words, about the year 1699; but we have never been able to find them.

PISTOIA, anciently *Piftoria*, in *Geography*, a city of Etruria, which is an epifcopal fee, remarkably well built, and from the unufual widenefs of the ftreets and folidity of its edifices, appearing both airy and magnificent. Of thefe buildings, the principal are the cathedral, the church called "Del Umilla," and the feminary. The dome of the firft, the front, or rather the veftibule of the fecond, and the general difpofition of the third, are much admired. Thofe eftablifhments called feminaries in Italy and France, are not merely academies or fchools, but colleges, where the young clergy are inftructed in the peculiar duties of their profeffion, under the infpection of the bifhop, during three years previous to the time of their receiving holy orders. Hence each diocefe has its feminary, which is always in the epifcopal city, and generally contiguous to the bifhop's palace. In Piftoia there are two public libraries. The river Ambrone flows clofe to the town. The furrounding country is not only fertile and well cultivated, but unufually picturefque.

PISTOL, a little fire-arm, borne at the faddle-bow, at the girdle, or in the pocket.

The piftol is faid to have taken its name from Piftoia, a city in Italy; where, as Fauchet tells us, it was firft made. Borel derives the word from *fiftula, pipe;* the barrel of this piece bearing fome refemblance to a flute.

It is faid that from harquebuffes (fee HARQUEBUSS) came piftole, or piftolets, with wheel-locks, the barrels of which were only one foot long, being the harquebufs in miniature. The Germans are faid to have ufed them in France before the French; and the horfemen who received them in the time of Henry II. were called "Piftoliers." They are mentioned as early as the year 1544, under the reign of Francis I. Piftols with a fimple fpring, inftead of the wheel formerly ufed, fufils and mufketoons, are of modern invention; but the inventors are not known. In the year 1658, the ufe of wheel-locked piftols was not abolifhed. The wheel-lock was a little folid wheel of fteel, fixed againft the plate of the lock of the harquebufs or piftol; it had an axis that pierced it in its centre; at the interior end of this axis which went into the lock, a chain was faftened, which twifted round it on the wheel being turned, and bent the fpring by which it was held; to bend this fpring, a key was made ufe of, into which the exterior end of the axis was inferted. By turning this key from left to right, the wheel was made to revolve, and by this movement a little flider of copper, which covered the pan with the priming, retired from being over it; and by the fame movement the cock, armed with a flint like the cock of a fufil, was in a ftate to be difcharged, on pulling the trigger with the finger, as in ordinary piftols; the cock then falling on the wheel, produced fire, and communicated it to the priming.

PISTOL *Bay*, in *Geography*, a bay on the northern extremity of Newfoundland. A late writer (1768) on the probability of a North-weft paffage, mentions this bay as the only remaining part of Hudfon's Bay where this weftern communication may exift. But this has been examined; and upon the authority of captain Chriftopher, who failed from fort Churchill in the year 1761, for the purpofe of examining Chefterfield's inlet, through which it was fuppofed there might be a paffage to the Weftern ocean, the reader may be affured that there is no inlet of any confequence in all that part of the coaft. Nay, he has, in an open boat, failed round the bottom of what is called Piftol bay, and inftead of a paffage to a weftern fea, found it does not run above three or four miles inland. See NORTH-WEST *Paffage*.

PISTOLE, DOUBLOON, or *Doblon*, in *Commerce*, a gold coin ftruck in Spain.

The piftole of exchange, as a money of account in foreign exchange (*i. e.* dobloon de plata), was valued at 32 reals of old plate, or 60 reals 8 maravedis vellon; but in commercial tranfactions within the country, it was reckoned only at 60 reals. After the year 1772, when a new coinage took place, the gold coins current in Spain have been as follow: the dobloon of 8 efcudos, or quadruple piftole, which paffes for 320 reals vellon; the dobloon of 4 efcudos, or double piftole for 160; the dobloon de oro, or piftole for 80; the efcudo for 40; and the coronilla, or veinten de oro, for 20.

In 1786, the ftandard of the gold was reduced to 21 carats for the different dobloons and their divifions, and to $20\frac{3}{5}$ carats for the coronilla, or veinten de oro. The quadruple piftole, or dobloon of 8 efcudos, coined fince 1786, contains $366\frac{1}{6}$ troy grains of fine gold, and is therefore worth 3*l.* 4*s.* $9\frac{1}{2}$*d.* valued in Englifh gold coin; and the fubdivifions of the quadruple are in proportion: the allowance for remedy may be valued at 6*d.* in the quadruple. By the affay of the London mint, the weight of the quadruple is 17 dwt. 8 gr., and its finenefs $4\frac{1}{2}$ gr. worfe than Englifh ftandard: hence its value in Englifh gold coin is 3*l.* 4*s.* $0\frac{1}{2}$*d.* The value of gold in the Spanifh coins is to that of filver as 16 to 1.

The affay, weight, &c. of the different Spanifh gold coins, are as follow.

	Affay.	Weight.	Contents in pure Gold.	Value in Sterling.
	car. gr.	oz. dwt. gr.	grs.	L. s. d.
Quadruple piftole, or dobloon, coined before 1772	W. 0 $1\frac{1}{2}$	0 17 $8\frac{1}{2}$	375.4	3 6 $5\frac{1}{4}$

The

The impreſſions on the gold coins of Spain are as follow: on the doubloon or piſtole is the head of the reigning king, with name and title; thus, CAROL. III. D. G. HISP. ET IND. REX, that is, Charles III., by the grace of God, king of Spain and the Indies: reverſe, arms of Spain, with the collar of the golden fleece; legend, in 1740, INITIUM SAPIENTIÆ TIMOR DOMINI, the fear of the Lord is the beginning of wiſdom; in 1762, NOMINA MAGNA SEQUOR, I follow great names; in 1763, IN UTROQUE FELIX AUSPICE DEO, happy in both under the divine auſpices: there is alſo at the bottom a letter to mark the place where the piece was coined; thus M, with a crown over it, ſignifies "Madrid;" M with an O over it, "Mexico:" there are alſo one or two other letters, which vary, being the initials of the moneyer's name. The double, quadruple, and half piſtoles bear the ſame impreſſions: but in modern coins, the half piſtole is marked "1 S," 1 ſcudo, or gold crown; the ſingle piſtole "2 S," and the others in proportion. The pieces coined between 1700 and 1723 bear no head, but have the arms, and the king's name with DEI GRA.; on the reverſe, a croſs ſurrounded with different ornaments; legend, HISPANIARUM REX. Thoſe coined before that period are not round, but of an irregular ſhape, and their impreſſions are very imperfect.

The doubloon of 1809, coined by Joſeph Bonaparte, bears on the front his head, with the legend, JOSEPH NAP. D. GR. HISP. ET IND. R. *i. e.* Joſeph Napoleon, by the grace of God, king of Spain and the Indies: reverſe, arms of Spain with a crown; legend, IN UTROQUE FELIX DEO AUSPICE, as before. The diviſions of the doubloon bear the ſame impreſſions.

The coronilla, or golden dollar, bears the ſame impreſſions as the doubloon, except with regard to the legends. Thoſe of an ancient date have on one ſide the king's name, with D. G., and on the reverſe HISPANIARUM REX; whilſt thoſe coined in 1786, &c. bear the name and title on the ſame ſide; and there is no inſcription on the reverſe except initials, as in the doubloon.

In Germany, under the name of piſtoles are included the Saxon Auguſt. d'ors, Pruſſian Frederick d'ors, Brunſwick Carl d'ors, Hanoverian George d'ors, Daniſh Holſtein Chriſtian d'ors, and the piſtoles of Heſſe, the Palatinate, Hildeſheim, and Mecklenburg; all reckoned at five rixdollars current; 35 pieces of each of theſe ſorts of money are to weigh a Cologne mark, and the gold to be $21\frac{3}{4}$ carats fine; ſo that $38\frac{6}{17}$ pieces contain a Cologne mark of fine ſilver. An allowance is, however, generally made for a deficiency in weight and fineneſs, and they are current, in moſt places, as long as $35\frac{1}{2}$ pieces weigh a Cologne mark of gold, $21\frac{1}{2}$ carats fine: they are then called "paſſier piſtoles." The aſſay of the George d'or of Hanover is W. 0 car. $1\frac{1}{4}$ gr.; weight, 0 oz. 4 dwt. $6\frac{1}{2}$ gr.; the contents in pure gold 92.6 gr.; and value in ſterling, 16*s.* $4\frac{1}{2}$*d.* The aſſay of Heſſe-Caſſel piſtole is W. 0 car. $2\frac{1}{2}$ gr.; weight, 0 oz. 4 dwt. $7\frac{1}{4}$ gr.; contents in pure gold, 92; value in ſterling, 16*s.* $3\frac{1}{2}$*d.* Aſſay of Manheim piſtole W. 0 car. $1\frac{1}{2}$ gr.; weight, 0 oz. 4 dwt. $6\frac{1}{2}$ gr.; contents in pure gold, 92.5; value in ſterling, 16*s* $4\frac{1}{2}$*d.*. The George d'or of Hanover bears on the front the king's arms; legend, GEORG. II. D. G. M. B. F. ET H. REX. F. D.; reverſe, V THALER (5 rix-dollars of account), and under this the date; legend, BRUNS. ET LUN. DUX S.R. I.A. T.H. ET ELECT. The piſtole of Heſſe-Caſſel bears the head of the reigning prince, with his name and titles, thus: WILHELMUS IX. D. G. HESS. LANDG. HAN. COM., William IX. by the grace of God, landgrave of Heſſe, count of Hanau; reverſe, a ſtar, and within it, the legend, VIRTUTE ET FIDELITATE, by courage and fidelity; in the centre, a lion. Other piſtoles, coined in 1794, &c. bear on the reverſe a lion at reſt with ſtandards and military trophies, and over this 5 THALER.

The piſtole of Manheim bears the head of the reigning prince, with name and title, thus: CAR. THE. C. P. S. R. I. A. T. ET EL. that is, Charles Theodore, count palatine, high ſteward and elector of the holy Roman empire; reverſe a crown, formed by four crowns, and four cyphers of the letters C. T.; legend, DOMINUS REGIT ME, God directs me.

In various parts of Italy, the piſtole is known under the name of doppia.

In Geneva the gold coins are the old piſtole of 11 livres 10 ſols; and the new piſtole coined ſince 1752, worth 10 livres current, or 35 florins, with double and triple piſtoles in proportion. The aſſay of the old piſtole of Geneva is W. 0 car. 2 gr.; weight, 0 oz. 4 dwt. $7\frac{3}{4}$ gr.; contents in pure gold, 92.5 gr.; value in ſterling, 16*s.* $4\frac{1}{2}$*d.* The aſſay of the new piſtole is W. 0 car. $0\frac{1}{2}$ gr.; weight, 0 oz. 3 dwt. $15\frac{3}{4}$ gr.; contents in pure gold, 80; value in ſterling, 14*s.* 2*d.*

The aſſay of the piſtole of the Helvetic republic of 1800 is W. 0 car. $1\frac{1}{2}$ gr.; weight, 0 oz. 4 dwt. $21\frac{1}{2}$ gr.; contents in pure gold, 106 gr.; value in ſterling, 18*s.* 9*d.* The aſſay of the piſtole of Lucerne is W. 0 car. $1\frac{1}{2}$ gr.; weight, 0 oz. 4 dwt. $21\frac{1}{2}$ gr.; contents in pure gold, 106 gr.; value in ſterling, 18*s.* 9*d.* The aſſay of the piſtole of Soleure is W. 0 car. $1\frac{3}{4}$ gr.; weight, 0 oz. 4 dwt. 22 gr.; contents in pure gold, 106.8 gr.; value in ſterling, 18*s.* $10\frac{3}{4}$*d.* The impreſſions on the piſtole of the Helvetic republic are a ſoldier carrying a ſtandard; legend, HELVETISCHE REPUBLICK, Helvetic republic; reverſe, a crown of oak, containing 16 FRANKEN: the double piſtole is marked 32 FRANKEN. The piſtole of Lucerne bears the arms of the city, with the legend, RESPUBLICA LUCERNENSIS; reverſe, a wreath of laurel, containing 12 M 2. GL., and under this the date. The double piſtole is marked 24. The piſtole of Soleure bears a warrior carrying a ſtandard; legend, S. URSUS MARTYR; reverſe, arms of the city; legend, RESPUBLICA SOLODORENSIS, republic of Soleure. The double and half piſtoles bear the ſame impreſſions.

The aſſay of the piſtole, or doppia, of Piedmont, of 1741 to 1785, is W. 0 car. $1\frac{3}{4}$ gr.; weight, 0 oz. 6 dwt. $4\frac{1}{2}$ gr.; contents in pure gold, 134.2 gr.; value in ſterling, 1*l.* 3*s.* 9*d.* The aſſay of the piſtole coined ſince 1785 (half, &c. in proportion) W. 0 car. $1\frac{3}{4}$ gr.; weight, 0 oz. 5 dwt. 20 gr.; contents in pure gold, 127.8 gr.: value in ſterling, 1*l.* 2*s.* $7\frac{1}{2}$*d.*; The aſſay of the doppia or piſtole of Genoa, (the pieces of of 2, 4, and 5 piſtoles in proportion) is W. 0 car. $1\frac{1}{2}$ gr.; weight, 0 oz. 4 dwt. $7\frac{1}{2}$ gr.; contents in pure gold, 93.4 gr.: value in ſterling, 16*s.* $6\frac{1}{4}$*d.* For other particulars relating to the piſtole, both as a money of account and as a coin, we refer to Kelly's Univerſal Cambiſt.

N.B. W. every where denotes worſe than the Engliſh ſtandard.

PISTOLOCHIA, in *Botany*, a name uſed by ſome authors for the plant of which the Virginian ſnake-root of the ſhops is the root.

PISTON, a part or member in ſeveral machines, particularly pumps, air-pumps, ſyringes, &c. called alſo the *embolus*, and popularly the *ſucker*.

The piſton of a pump is a ſhort cylinder of metal, fixed exactly to the cavity of the barrel, or body; and which, being worked up and down alternately therein, raiſes the water; and when raiſed, preſſes it again, ſo as to make it force up a valve with which it is furniſhed, and ſo eſcape through the noſe of the pump.

There are two ſorts of piſtons uſed in pumps; the one with

with a valve, which is called a bucket; and the other without a valve, which is called a forcer. See PUMP.

The pistons of air-pumps, syringes, &c. see described under AIR-PUMP and SYRINGE.

PISTORIA, in *Ancient Geography*. See PISTOIA.

PISTRINA, in *Geography*, a town of Servia; 48 miles S.W. of Nissa, and 100 miles E. of Ragusa.

PISTRITZER, a river of Saxony, which runs into the Elbe, near Wittemberg.

PISTYRUS, or PISSIRUS, in *Ancient Geography*, a town in the western part of Thrace, near Mestras, in the territory of which, according to Herodotus, was a lake thirty stadia in circuit.

PISUERGA, in *Geography*, a river of Spain, which springs in the N. part of Old Castile, and runs into the Duero; 10 miles S.W. of Valladolid.

PISUM, in *Botany*, the Pea, an ancient name, whose origin is lost in its antiquity. Some of the learned are content to deduce it from the Greek πισον, which means the same thing, and which others derive from πτισσω, *to stamp*, or *bruise*, because it was customary to take off the skin by such means. De Theis thinks the Celtic *pis*, which is *pisen* in the plural, (he by mistake says singular,) is the common root of this word in all languages. Hence the Anglo-Saxon *pisa*; the English *pea*, *pease*, and still in obsolete Norfolk *peasen*; the French *pois*, and for a pea-field, in old language, *pesiere*; the Italian *piso*; the Welsh *pus*; all synonimous. Linn. Gen. Pl. 374. Schreb. 496. Willd. Sp. Pl. v. 3. 1070. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 760. Ait. Hort. Kew. v. 4. 302. Juss. 360. Tourn. t. 215. Lamarck Illustr. t. 633. Gærtn. t. 152. (Ochrus; Tourn. t. 219, 220.)—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, five-cleft, acute, permanent; the two upper segments broadest. *Cor.* papilionaceous. Standard very broad, inversely heart-shaped, reflexed, emarginate with a little point. Wings two, roundish, converging, shorter than the standard. Keel compressed, half crescent-shaped, shorter than the wings. *Stam.* Filaments in two distinct sets; one simple, uppermost; and nine awl-shaped, united more than half-way into a cylinder, split along its upper side; anthers roundish. *Pist.* Germen oblong, compressed; style ascending, triangular, membranous, keeled, its sides bent outwards; stigma united with the upper angle, oblong, villous. *Peric.* Legume large, long, roundish, or compressed towards the base, terminating in a point directed upwards, of one cell and two valves. *Seeds* several, globose.

Obs. *Ochrus* of Tournefort has an oblong scar to the seed; *Pisum* of the same author has a roundish scar.

Ess. Ch. Style triangular, keeled and downy at the upper side. Two upper segments of the calyx broadest. Stamens in distinct sets.

1. P. *sativum.* Common Pea. Linn. Sp. Pl. 1026. Willd. n. 1. Ait. n. 1. (Pisum; Riv. Tetrap. Irr. t. 36. Camer. Epit. 213. P. majus; Matth. Valgr. v. 1. 389. Ger. Em. 1219.)—Footstalks cylindrical. Stipulas rounded and crenate at the base. Stalks bearing several flowers.—Native of the south of Europe. Dr. Sibthorp found it, apparently wild, in various parts of Greece. The *root* is annual. *Stem* branched, leafy, smooth, climbing by means of tendrils, and various in height. *Leaves* alternate, pinnate, of about six, elliptical, nearly opposite, mostly entire leaflets, on a common *footstalk*, ending in a compound *tendril*. *Stipulas* in pairs at the insertion of the footstalk, much larger than the leaflets; rounded, lying over each other, and copiously crenate, at the base. *Stalks* axillary, solitary, bearing two or more large, pearly-white, inodorous *flowers*. Upper segments of the *calyx* broader, hardly shorter, than the rest; all of them ovate, acute. *Legume* about a finger's length, smooth.

Of this valuable plant botanists have distinguished several varieties, and gardeners several more. Among the latter are the Marrowfat, the Rounceval, the Hotspur, &c. Among the former are the Sickle Pea of Miller, Pisum siliqua curva; Rivin. Tetrap. Irr. t. 37; the Dwarf Pea, P. nanum of the same author, t. 38. f. 2; the Sugar Pea, P. cortice eduli; Tourn. Inst. 394; and the Rose, Crown, or Topknot Pea, P. umbellatum; Mill. Dict. ed. 8. n. 3. Ger. Em. 1220. P. comosum; Riv. Tetrap. Irr. t. 38. f. 1. These two last, (the Sugar and the Crown Peas,) agree in the remarkable property of having no hard rigid lining to the legume, so that their pods may be boiled and eaten entire, having moreover a very sweet and agreeable flavour. The *flowers* of the Crown Pea, at least, have elegant rose-coloured wings, and their stalks grow many together about the top of the stem, rendering the plant very ornamental, and the crop abundant. We have often been tempted to consider this as a distinct species. The notches of the *stipulas* are, as Miller remarks, about four, being much fewer than in the Common Pea; but we can find no sufficiently clear and permanent specific mark.

2. P. *arvense.* Field, or Grey Pea. Linn. Sp. Pl. 1027. Willd. n. 2. Ait. n. 2. Sm. Fl. Græc. Sibth. t. 687, unpublished. (Pisi pulchra species, folio angulofo; Bauh. Hist. v. 2. 297. Moris. v. 2. sect. 2. t. 1. f. 4.)—Leaflets four on a stalk. Stipulas strongly crenate. Stalks single-flowered.—Native of fields in several parts of Europe. Dr. Sibthorp found it near Constantinople; and it is often in some degree naturalized with us. This seems scarcely more than a variety, or perhaps the true original state, of the first species, differing in having rather fewer *leaflets*, which are more frequently serrated; solitary purplish *flowers*, whose wings are of a violet purple; and rather more strongly crenate, often angular, *stipulas*.

3. P. *fulvum.* Tawny-flowered Pea. Sm. Prodr. Fl. Græc. Sibth. v. 2. 62. Fl. Græc. t. 688, unpublished. —Footstalks cylindrical. Stipulas rounded at the base, sharply toothed. Stalks two-flowered. Legumes shortened. —Gathered by Dr. Sibthorp in Asia minor, probably near Smyrna. This is smaller than the preceding. *Leaflets* two or four, serrated. Base of the *stipulas*, rounded, dilated, very sharply and copiously toothed. *Flowers* elegant; their standard salmon-coloured, veined with crimson or scarlet; wings of an orange hue; keel of a tawny yellow. *Legume* scarcely more than an inch long, half-elliptical. *Seeds* from three to five.

4. P. *maritimum.* Sea Pea. Linn. Sp. Pl. 1027. Willd. n. 3. Ait. n. 3. Sm. Spicil. 8. t. 9. Engl. Bot. t. 1046. Fl. Dan. t. 338.—Footstalks slightly flattened above. Stem angular. Stipulas arrow-shaped. Stalks many-flowered. —Native of the stony sea beach in the north of Europe, and according to Linnæus and Pursh, of North America also. It was first noticed in England between Aldburgh and Orford, Suffolk, when a year of scarcity caused it to attract the observation of the distressed peasantry, who derived great relief from these wild peas, as Caius, Gerarde, and others relate; see Ger. Em. 1250. The long deep perennial *roots* were also found to be sweet and eatable. The *stems* are short, procumbent, thickly clothed with greyish glaucous *leaves*, each composed of six or eight oval, entire, generally alternate leaflets, and ending in a divided *tendril*. *Flowers* handsome, variegated with purple and blue, many together

together on longish axillary stalks. *Legumes* linear-oblong; their young *seeds* about as good as the Grey Pea.

5. P. *Ochrus*. Wing Pea. Linn. Sp. Pl. 1027. Willd. n. 4. Ait. n. 4. Sm. Fl. Græc. Sibth. t. 689. (Ochrus sive Ervilia; Ger. Em. 1249. Aracus niger; Matth. Valgr. v. 1. 384.) Leaflets two, on winged decurrent footstalks. Flower-stalks single-flowered.—Native of Italy, Spain and the Levant. It was cultivated in the English gardens in Gerarde's time, being a hardy annual, flowering in June and July. The very large broad wings of the *footstalks* mark it sufficiently. Each lobe of these bears, at the summit, an oval glaucous *leaflet*, sometimes more, and the middle part ends in a many-branched tendril, winged at the base. *Flower-stalks* axillary, solitary, much shorter than the footstalks, single-flowered. *Corolla* pale buff. *Legume* an inch and an half long, channelled and winged at the back. Of the quality of the peas we have no information.

Pisum, in *Gardening*, comprises plants of the hardy herbaceous kinds, of which the species cultivated are; the common pea (P. sativum); the sea pea (P. maritimum); and the yellow-flowered pea (P. ochrus).

Of the first sort there are two principal varieties, the white and grey; and several sub-varieties, the principal of which are:

Early Kinds.—The early golden hotspur; early Charlton hotspur; Nichols's early golden hotspur; the early Charlton; the Reading hotspur; Masters's hotspur; Ormrod's hotspur; early dwarf hotspur; Leadman's dwarf; fan Spanish dwarf; early dwarf frame pea; pearl pea; cluster pea; royal green pea; Essex hotspur; the dwarf pea; the sugar pea.

Late Kinds.—Spanish morotto; nonpareil; sugar dwarf; sickle pea; marrowfat; dwarf marrowfat; rose or crown pea; rounceval pea; grey pea; large grey pea; crooked grey pea; long-bearing pea; green field pea; white field pea; pig pea.

Many of the first sub-varieties are very early, and being low growers, require sticks of three or four feet only in height, and often not so much. New varieties of these are raised almost every year, which, because they differ in some slight particular, are sold at an advanced price, and have frequently the names of the persons who raised them, or the place where they first grew. These varieties are not permanent, and without the greatest care will soon degenerate.

Method of Culture in the open Ground.—All the sorts of the first kind are raised from seed sown annually; and as those of one sowing continue but a short time in bearing, several sowings are requisite each season, to continue successions for the table all summer; each sowing to remain where sown, choosing a warm dry border, &c. for the earliest crops; and for the succeeding ones, any of the common quarters, in a free exposure, distant from the shade of trees, &c., but open to the sun.

For the late crops the more moist parts are the best.

The general season for sowing is any time in open weather, from the lattter end of October, or in November, until May or June.

But in order to have green peas as early as possible, recourse must be had to the assistance of hot-beds, by the aid of which they are obtained in March and April, and continued till the coming in of the natural ground crops, in the latter end of May or beginning of the following month.

The early and first general Crops.—Towards the latter end of October, in November or December, as the weather may be convenient, the earliest crops should be put into the ground. In warm soils and situations it is always advisable to sow a few in the two former months; but in general, and especially in open exposed grounds, November and December is time enough to begin the principal sowings. For this purpose the earliest Charlton or golden hotspurs are the most proper.

And in order for their reception a warm south border, or some other dry, sheltered, sunny situation should be dug over and prepared; when, in a dry day, drills should be drawn by a line, ranging south and north, to enjoy the greater advantage of the sun's influence, making them an inch and a half deep, and two feet and a half at least asunder; but if designed for sticks, three feet and a half will be a more proper distance. Then the seed should be scattered in evenly along the middle of each drill, rather thickish, as they are liable to accidents from vermin and the season, covering them in regularly with the earth either with a rake or hoe, being careful that they are all equally covered the depth of the drills; and then with a rake lightly trim the surface smooth; which finishes the work.

The peas begin to germinate in a fortnight, if mild weather, and come up in three weeks or a month, but seldom in less time at this season; when the plants are to be managed as directed below.

Another sowing should be performed in three weeks or a month after this; or when the first was sowed in October or early in the following month, it is better to repeat the sowing in a fortnight or three weeks, for fear the first should fail; and after this continue sowing once in three weeks or a month all winter in mild weather. But towards spring a principal crop of the Reading and other large hotspurs should be sown; and as the season advances, the sowings be made in more open exposures, and more in quantity than the early ones; and as the spring draws on, the sowings should also be repeated oftener; as from the close of the year till the beginning of April, they should be once in three weeks; and from that time till May once a fortnight, especially as the warm weather increases.

The winter and early spring sowings differ materially in the time they require to germinate: those sown any time in winter are sometimes three weeks or near a month before they appear, while those sown towards spring come up much sooner, in the later spring sowings, often in a very short time.

In the later of the above sowings, some of the dwarf sorts may be introduced; as Leadman's dwarf, both for middle and late crops.

As the plants of each sowing come up, and are advanced two or three inches in height, it is proper to begin the first culture by drawing a little earth with a hoe, or small rake, lightly up to their stems on each side of the different rows to strengthen and forward their growth, repeating the earthing once or twice at proper intervals, as occasion may require, and at the same time cutting up and clearing away all weeds; and when the crops are six or eight inches in height, those designed for support should be sticked.

As the earliest crops are often in danger from the severity of frosts, it is proper, when they are about an inch and a half high, to draw a little fine earth lightly up to their stems in a dry day; it will also be of much advantage to give occasional protection to such crops in severe weather, by covering them lightly with long, light, dry litter, of the strawy kind, or by mats; which, where there is but a moderate quantity in warm borders, may be more easily effected; but this need only be practised in very severe frosts. They must however be carefully uncovered every fine day in temperate weather; and the moment the frost disappears the covering be entirely removed; as they must by no means be kept too close, which would draw them up weak and tender.

When

When in bloſſom, if the weather ſhould prove dry and warm, a few good waterings in the mornings will be beneficial; and when the bloſſoming plants are advanced a conſiderable height, if they are then topped, it will promote their podding and coming to perfection.

As to the ſucceeding crops of the different kinds, all they require is hoeing up the earth to their ſtems occaſionally, and cutting up all weeds when they appear; thoſe deſigned for ſupport being always ſticked as ſoon as they are half a foot high, or a little more, before they begin to fall down on their ſides, providing ſticks about four or five feet long, and placing one range to each row principally on the ſouth or moſt ſunny ſide of the rows, as the plants naturally incline towards the ſun, and of courſe more readily attach themſelves to the ſticks.

In the culture of the larger kinds, for ſucceſſional general crops, ſuch as the marrowfats, Spaniſh morottos, &c. they may be begun ſowing in January, the dwarf marrowfats firſt; but the three following months are the moſt proper for the general crops of all the large kinds; a free expoſure in the moſt open quarters being made uſe of, drawing drills by line, about an inch and a half or two inches deep, and not leſs than a yard aſunder, and when ſticked, four feet, and for the largeſt ſorts four feet and a half or five feet, in ſingle or double rows.

In theſe caſes the ſeed ſhould be ſown thinly along the middle of each drill, drawing the earth evenly over them with the rake, hoe, or feet, covering them equally the depth of the drills, and raking the ſurface ſmooth; theſe ſowings being repeated once a fortnight or three weeks; and as the ſpring advances once a fortnight, eſpecially from the beginning of April until the end of the following month. Afterwards a few may be ſown every ten or twelve days. Late ſowings are, however, ſeldom very fruitful, being often attacked with the mildew; but it is proper to endeavour to have ſome as long in the ſeaſon as poſſible.

When theſe different crops are come up about three inches high, they ſhould have earth laid up to them on each ſide of the rows, cutting down all weeds, and repeating the hoeings occaſionally according as the growth of weeds may require; and when they are half a foot, or eight or ten inches high, they ſhould have the ſticks placed to them; which for theſe large ſorts require ſticks ſix or ſeven feet high at leaſt, placing them on the ſunny ſide of the rows, as directed above.

For late crops, any of the ſorts, either hotſpurs or larger kinds, may be continued ſowing all May and until the middle or latter end of June; likewiſe ſome of the dwarf ſorts at a later period for late production. It may be proper to ſow larger portions of Rouncivals for the lateſt crops, on account of their being rather the hardieſt to ſtruggle with the ſummer's heat and drought, and thereby moſt to be depended on for a late production.

For theſe crops ſome of the moiſteſt ground ſhould be choſen; and if the weather ſhould prove very dry and hot, it will be of importance to ſoak the ſeed in ſoft water ſix or eight hours previous to ſowing; or the drills may be well watered after it has been done; either of which will promote their riſing expeditiouſly and more regularly.

It may be obſerved, in reſpect to the times of ſowing, that it is a good rule, in the different ſorts, as ſoon as one crop appears fairly above ground, to ſow another to ſucceed it of the ſame kind, ſo as to have a regular ſucceſſion of crops following one another in bearing; and if a crop of marrowfats, &c., and another of hotſpurs, be ſown on the ſame day, the hotſpurs will come into bearing a fortnight the ſooneſt, and the marrowfats will arrive to a bearing ſtate about the time the others are going out, juſt in due time to ſucceed them; which ſhould be attended to in order to have theſe ſorts form a regular ſucceſſion to each other.

In gathering the crops, both hands ought always to be employed; one to hold the peduncle or footſtalk of the fruit, while the other pulls the pods; otherwiſe the ſtem or main ſtalk of the plant, being ſlender, fragile, and weak, is liable to be broken and deſtroyed; and the gatherings ſhould always be regularly performed according as the pods fill, never letting them ſtand to grow old, as they are in the greateſt perfection for eating while green, and the plants continue longer in bearing. Crops of peas continue only about a fortnight in full bearing, during which time they furniſh a plentiful gathering of pods in their perfection; though in moiſt ſhowery weather they ſometimes continue ſhooting and flowering three or four weeks; but the produce after the firſt fortnight is generally inferior both in quantity and quality.

As ſoon as the crops are paſt bearing, all the ſticks ſhould be taken up and tied in bundles, being ſet upright in any dry corner for future uſe.

Method of Culture in Hot-Beds.—In order to have green peaſe as early in the year as poſſible, recourſe muſt be had to the aſſiſtance of hot-beds; and the proper ſorts for this purpoſe are the early dwarf kinds, which by this means may be brought into bearing in March, or the following month.

In this intention, it is rather the beſt mode to raiſe the plants firſt in the natural ground, by ſowing in October, or the following month, giving occaſional protection from froſt; and when one or two inches high, to tranſplant them into the hot-bed, in January, or the beginning of the following month: as by this practice the luxuriant growth of the plants is ſo checked by the removal, that they ſhoot more moderately, and thereby bloſſom and bear ſooner, and more abundantly.

The ſowings ſhould be performed in a warm, dry, ſouth border, or in ſome ſimilar dry ſheltered part of light good earth, in a bed of proper dimenſions, to have the protection of a frame, &c. in ſevere weather; ſowing them in drills about a foot aſunder, in the manner as for the common crops. When they are come up, and advanced a little in growth, in a dry day, ſome fine earth ſhould be drawn up to their ſtems, giving ſuitable protection in bad weather.

But they may be ſown on a moderate hot-bed in December, or January, under frames, &c.; and when the plants are up, plenty of free air ſhould be admitted every temperate day, and be defended in the nights from froſt, ſnow, and cutting cold; or, ſome may be ſown in large pots, and be placed in a hot-houſe, &c. to bring up the plants quickly, for tranſplanting into the intended hot-bed in January. And they may be ſown at once in a hot-bed, at the above periods, to remain for bearing; but it is generally more eligible to have the plants previouſly raiſed an inch or two in height, either by early ſowing in the full ground, or forwarded under frames, or in a hot-bed, &c. as above, for tranſplanting into a freſh-made hot-bed for bearing.

In either of the above methods of raiſing the plants for tranſplanting, when advanced from one to two inches in growth, or little more, they are proper for planting out into the hot-bed to remain for fruiting.

In mild weather, towards the middle or latter end of January, or the beginning of the following month at furtheſt, a hot-bed for one or more of the largeſt three-light frames and glaſſes ſhould be prepared, which may be either of dung or or tan: the latter, where it can be obtained eafily at a moderate expence, is confiderably the beft for this purpofe. It fhould be made two feet and a half, or a yard thick, and covered with frames and lights; and when in a moderate temperature, the earth be put on for the reception of the plants. Any light, good, dry earth may be employed, which fhould be laid eight or ten inches thick all over the bed; then in a dry mild day, the plants may be taken up, raifing them with their roots as entire as poffible, with what earth will readily hang about the fibres; and after drawing fmall drills in the earth of the hot-bed, from the back to the front of the frame, a foot and a half afunder, and about an inch deep, the plants fhould be put in the drills, not more than an inch apart, covering in the earth clofe to their roots and ftems, and giving a very light watering, juft to fettle the earth; after which the lights fhould be put on, being careful to raife them occafionally at the upper end, to give vent to the fteam, &c. And at firft planting out, when in funny weather, if the plants fhould flag, a moderate fhade fhould be given in the middle of the day, till the plants have taken root, and eftablifhed themfelves.

After this, frefh air muft be admitted to the plants daily, in fine weather, to ftrengthen them, by tilting the upper end of the lights, according to the temperature of the bed and outward air; keeping them clofe in cold nights, and covering alfo with mats. Occafional moderate waterings fhould likewife be given in fine days; and, as the plants advance in growth, a little earth be drawn up to their ftems once or twice; repeating the moderate refrefhments of water frequently, as the warm feafon advances; which may be given more freely when the plants are in bloom. And according to the advanced growth of the plants, and increafed warmth of the weather, a larger fhare of frefh air in proportion fhould be given; and when they are in bloffom, if the fun at any time appears too violent for them through the glaffes, it is advifable to give a very flight fhade an hour or two in the heat of funny days: likewife, when in full bloffom, and fruiting, to admit plenty of free air; even fometimes, in fine days, fhoving the glaffes entirely off; alfo ftill continuing the waterings more abundantly during the time of fetting and growth of the pods, and indulging them with the benefit of warm fhowers of rain. In this way, the plants may be brought to bearing in March or April; and by a fucceffion of two crops, in hot-beds made at three or four weeks' interval, and managed as above, a fupply be continued till the natural ground crops come into bearing in May.

Where there is the convenience of fruit forcing-houfes, hot-walls, &c. a few of the earlieft kinds, either previoufly raifed in young plants an inch or two in growth, as in the hot-bed culture, or, in default of it, the feed fown; and which being in pots, are placed in thefe departments: or, where there are internal borders of earth, fome young plants may be placed therein. The internal moderate heat of the above departments, effected either by bark-beds, &c. or fire, or both occafionally, in a requifite degree for forcing the fruit-trees to early production, forwards them alfo, fo as to have fome for gathering in the moft early feafon, in a fmall proportion.

Method of Culture in the Field.—Where defigned to raife crops, in order to gather the produce green and young, for the fupply of markets, November, or rather December, is foon enough to begin the firft fowings, efpecially in open expofed grounds; a dry light foil being chofen for the more forward fowings. As to the forts, any of the hotfpurs may be ufed for the forward crops; and for a general crop, the Reading hotfpur is excellent; and after that fort, the Mafters's and Ormrod's, &c.; but of the large kinds, the marrowfats and Spanifh morattoes fhould be chofen for the main crops.

The ground for their reception muft be prepared by proper ploughing and harrowing; drills are then to be drawn with a hoe crofsways the lands, or with a drill-plough lengthways, two feet at leaft, or two and a half afunder for the early, and three for the larger forts. As no fticks are intended for thefe large field crops, having fown the feed, it fhould be covered in either with the hoe, rake, or harrow; but the hoe or rake will cover them more evenly, and almoft as expeditioufly. When they come up, they muft be kept clean from weeds, by broad-hoeing; but this is fometimes performed in fields by horfe-hoeing, for the fake of expedition; which, having hoes fixed in a fort of plough horizontally, is drawn by a horfe between the rows, a man holding the plough-fhafts to guide it. But as this can only cut down the weeds, a common drawing hand-hoe muft be ufed to earth up the plants: though this is often difregarded in the field-culture, it, however, proves very beneficial to the crops.

In thefe cafes, the rows fhould be laid down fo as to face the fun as much as poffible.

Method of faving Seed.—In order to fave feed, fome of each fort fhould be fuffered to ftand entirely for that purpofe, or fome fown of each purpofely in different parts; and the whole produce fuffered to remain and ripen for feed.

In the latter mode, they fhould be fown in February, in fome open ground, in rows two or three feet afunder, no fticks being required; and, when the plants come up, be kept clean from weeds by hoeing, the earth being laid up to their ftems once or twice. When they are in bloom, they fhould be examined row by row, to fee if there be any degenerate fort, which, when prefent, muft be pulled out; or if any improved variety be difcovered, to mark it; which is the only method to preferve both the purity of the known forts, and to procure new varieties. For example: if amongft the hotfpurs any large forts appear, they fhould be removed directly; alfo any hotfpurs, &c. from amongft the large kinds; and different forts of any of thefe from each other. And if any new fort difcovers itfelf, either by flowering earlier than all the reft, or poffeffing fome other fingularity, or noticeable merit for culture, it fhould be carefully marked; the feed being faved feparate, to fow feparately for furnifhing a proper increafe.

According as the feeds of the different forts ripen in July and Auguft, which is difcoverable by the pods changing brown, and the feed becoming a little hard, the haum fhould be cut or pulled up in dry weather, and expofed in heaps to the fun, turning them every day; and when the feed is become perfectly dry and hard, it may either be threfhed out directly, or ftacked up in a dry fituation, till another opportunity: but when threfhed, each fort muft be kept feparate, and, when properly cleaned, be put up in facks, with the name of each upon them.

PIT *and Gallows*, in our *Ancient Cuftoms*. See FURCA and FOSSA.

PITS, *Brine*, the name given by the people of Worcefterfhire and Chefhire, to the wells or pits affording the falt water, out of which they extract the falt.

Thefe waters, though they all contain falt, yet have other things alfo in them, and thefe not in fmall quantity. They all contain a very large proportion of ftony matter: this is common to the whole fet, but particular fubftances befide this

this are found in the particular pits. At Northwich, in Chefhire, there are four pits, the water of which ftinks very ftrongly of fulphur, and contains fo much vitriol, that it will turn black like ink, with a decoction of galls: yet this is boiled into a very fine and pure kind of falt, common at our tables under the name of bafket-falt, and having no fuch properties.

There is a vaft quantity of ftony matter precipitated from thefe pans of brine, in the boiling of them to falt: this is partly faved in fmall pans fet at the fide of the boiler, and partly precipitates to the bottom of the pan, where it forms a cruft like that at the bottom and fides of our tea-kettles, which the workmen find it neceffary to remove every week; but there is no vitriol or fulphur feparated. Phil. Tranf. N° 150.

In the country near where thefe brine-pits are, the inftruments ufed in boring often bring up fine and hard falt; fo that they give proofs of there being rocks of falt in many places.

All along the river Weever, on each fide, the earth affords brine wherever it is opened; but all thefe are not fit for boiling, many of the pits affording a brine too weak to be worked to any advantage. The very ftrongeft pits fometimes alfo become at once too weak: this is owing to the irruption of frefh fprings into them, and fometimes the river itfelf makes its way into them, and overflows them with fuch a quantity of frefh water, that they are utterly fpoiled. The brine-pits at Wefton, near Stafford, afford a brine that ftinks like rotten eggs: this turns inftantly to ink with galls, and purges and vomits violently, if taken even in a fmall quantity. This, in boiling, depofits a white flaky fand, or ftony matter, without fmell or tafte, and the falt is pure and fine.

The pit at Droitwich, in Worcefterfhire, affords no fand in the boiling, nor any the leaft fediment of the ftony matter at the bottom of the pan, and the falt is the pureft of all the others; and by the people of the country it is efteemed the moft wholefome, becaufe of its being without the fand.

This and the other pits hereabout, all have the fmell of rotten eggs, efpecially after a little reft, as on the Monday morning after the Sunday's reft. If meat be put to pickle in the brine of thefe pits, inftead of being preferved, it will ftink in twenty-four hours, fometimes in twelve, yet they yield the beft falt of any inland pits in the world.

The fulphur fpaws of Yorkfhire, which are very numerous in different parts of the county, all ftink violently of rotten eggs; but if well drawn and worked, they would prove as inoffenfive as the reft, and only fo many weaker or ftronger brine pits; and the fmell is no other than that of the Chefhire and Staffordfhire brine, when it has been left fome time at reft. It is remarkable, that though the ftony matter is depofited in fuch vaft plenty by the waters of all our falt fprings, it is not found in any abundance in thofe places where falt is made out of fea-fand, as in Lancafhire, and fome other places; fo that it is much more than the natural quantity of fpar contained in water that is thus depofited; and indeed it appears from trial, that the brine of our falt fprings, in general, contains more than twenty times the quantity of fpar that common water does.

This ftony matter feparates itfelf from the water before the falt does, and thus it appears in many other waters impregnated with mineral particles. The vitriolic waters all contain ochre and falt, and in all thefe the ochre feparates itfelf firft in the boiling, and then the vitriol; and the ftony matter precipitated from common falt fprings affords, on an analyfis, the falt called *nitrum calcareum*, in confiderable abundance. Phil. Tranf. N° 156. See SALT.

PITS, *Forcing*, in *Gardening*, fuch as are formed and conftructed on fomewhat fimilar principles to thofe in hot-houfes, ftoves, &c., and which are found of very great ufe and advantage in raifing crops of culinary exotics, as cucumbers, and many other forts;—in forcing common vegetables, as afparagus;—in raifing young exotics, as pines and other plants;—or in producing grapes. For thefe general purpofes, pits have been conftructed with one fingle fire, which are capable of producing four different temperatures of heat at the fame time. They are, confequently, able to force all kinds of common vegetables, and capable of growing vines, pines, and melons, each in their proper climate, with one fire, and little trouble or expence. See HOT-HOUSE and STOVE.

PIT-*Coal*. See COAL.

Vegetables have been confidered as the materials for the formation of pit-coal; but M. Chaptal obferves, that a few forefts, being buried in the earth, are not fufficient to form the mountains of coal which exift in its bowels. He thinks fome provifion, greater and more proportioned to the effect, is requifite, and this he finds only in the prodigious quantity of vegetables which grows in the feas, and which is ftill increafed by the immenfe mafs of thofe that are carried down by rivers. Thofe vegetables carried away by the currents, are agitated, heaped together, and broken by the waves; and afterwards become covered with ftrata of argillaceous or calcareous earth, and are decompofed. It is eafier to conceive how thefe maffes of vegetables may form ftrata of coal, than that the remains of fhells fhould form the greater part of the globe. In confirmation of this theory, Chaptal alleges, the prefence of vegetables in coal mines; the impreffions of fhells and of fifh that are found in the ftrata of coal, and not unfrequently fhells themfelves; and alfo the evidence afforded by the nature of the mountains which furnifh coal, from which it appears that their formation is fub-marine; for they all confift either of fchiftus, or grit, or limeftone. The fecondary fchiftus is a kind of coal, in which the earthy principle predominates over the bituminous. As the origin of the fchiftus, on which the texture of the vegetable, and the impreffion of fifh are well preferved, is fub-marine, the fame muft likewife be the origin of the coal diftributed in ftrata through its thicknefs. The grit-ftone confifts of fand heaped together, carried into the fea by rivers, and thrown up againft the fhores by the waves. The ftrata of bitumen which are found in thefe cannot but come from the fea. Calcareous earth rarely contains ftrata of coal, but is merely impregnated with it; the bitumen forming a cement with the calcareous earth.

Pit-coal is ufually found in ftrata in the earth, almoft always in mountains of fchiftus or grit. The fecondary fchiftus is the bafis of all pit-coal, and the quality of the coal moftly depends upon the properties of this bafis. When the fchiftus predominates, the coal is heavy, and leaves a very abundant earthy refidence after its combuftion. As the formation of the pyrites, as well as that of coal, arifes from the decompofition of vegetable and animal fubftances, all pit-coal is more or lefs pyritous; fo that we may confider pit-coal as a mixture of pyrites, fchiftus, and bitumen. The different qualities of coal, therefore, arife from the difference in the proportion of thefe principles. When the pyrites is very abundant, the coal exhibits yellow veins of the mineral, which are decompofed as foon as they come in contact with the air; and form an efflorefcence of fulphat of magnefia, of iron, of alumine, &c. When pyritous coal

is

is set on fire, it emits an insupportable smell of sulphur; but when the combustion is insensible, inflammation is frequently produced by the decomposition of the pyrites; and it is this which occasions the inflammation of several veins of coal. When the schistus, or slaty principle, predominates in coals, they are then of a bad quality, because their earthy residue is more considerable. The best coal is that in which the bituminous principle is the most abundant, and exempt from all impurity. This coal swells up when it burns, and the fragments adhere together; it is more particularly upon this quality that the operation called desulphurating or purifying of coal depends. This operation is analogous to that in which wood is converted into charcoal. In the desulphuration, pyramids are made, which are set on fire at the centre: when the heat has strongly penetrated the mass, and the flame issues out of the sides, it is then covered with moist earth; the combustion is suffocated, the bitumen is dissipated in smoke, and there remains only a light spongy coal, which attracts the air and humidity, and exhibits the same phenomena in its combustion as the coal of wood. When it is well made, it gives neither flame nor smoke; but it produces a stronger heat than that of an equal mass of native coal.

It was long supposed that the smell of pit-coal is unwholesome; but the contrary is now proved. M. Venel has made many experiments on this subject, and is convinced that neither men nor animals are incommoded by this vapour. Mr. Hoffman relates, that disorders of the lungs are unknown in the villages of Germany, where this material of combustion is only used. Coal of a good quality, it is supposed, does not emit any dangerous vapour: but when it is pyritous its smell must be hurtful. The use of coal is generally applicable to the arts in a variety of ways. In Scotland lord Dundonald has erected furnaces in which the bitumen is disengaged from coal, and the vapours are received and condensed in chambers, by means of water, and these condensed vapours afford an ample supply of tar. M. Faujas has carried into execution a similar process at Paris, by setting fire to coal, and extinguishing it at the proper time, so that the vapour may pass into chambers containing water for the purpose of condensing them. This tar is said to be superior to that of wood. (See TAR.) Pit-coal likewise affords ammoniac by distillation, which is dissolved in water, while the oil floats above. When coal is deprived by combustion of all its oil and other volatile principles, the earthy residue contains the sulphats of alumine, iron, magnesia, lime, &c. These salts are all formed when the combustion is slow; but when it is rapid, the sulphur is dissipated, and there remain only the aluminous, magnesian, calcareous, and other earths. The alumine most commonly predominates. Chaptal's Elem. of Chemistry, vol. iii.

PIT, *Cock*. See COCK-*Pit*.

PIT, *Saw*. See SAW.

PIT *of a Theatre*, all that space between the amphitheatre or galleries, and the theatre or stage; called by the ancients *orchestra;* and by the French, *parterre*.

This being the most commodious part, it was here the Roman senate was placed. It has its name *pit*, in Latin *cavea*, from its being sunk below the level of the stage.

PIT-*Fish*, or PIT-*Visch*, in *Ichthyology*, the Dutch name of an East Indian fish, approaching very much to the nature of the European turdus, but that it has no scales; its body is not flat but rounded, and is variegated with blue and yellow spots; its eyes stand very prominent, and the fish is able, at pleasure, to thrust them out or draw them in; its back fin is prickly: it loves muddy and foul places, yet it is a very well tasted fish. See GOBIUS *Boddaerti*.

PITAMA, or PITAMAHA, in *Mythology*, the name of the god Brahma among the Hindoos; the creative power in their divine triad. See TRIMURTI.

PITAMBER, a name among Hindoo mythologists, given to their pastoral god Krishna, and sometimes also to Vishnu, and Narayana; who are probably the same deity under different names, varied according to the sectarial bias of the devotee.

PITANCIARIUS, PIETANCIARIUS, or *Pictantiarius*, an office in the ancient monasteries, whose business it was to provide and distribute the pittances of herbs and meat amongst the monks. See PITTANCE.

PITANE, in *Ancient Geography*, a town of Asia Minor, in Mysia, watered by the river Evenus, and distant 30 stadia from the mouth of the Caycus.

PITANGUA GUACU, in *Ornithology*, the name of a Brasilian bird of the starling kind, called by the Portuguese there the *bemetre*. It is of the size of the common starling; its beak is long, thick, and of a pyramidal figure; its head broad and flattened; its neck short, which, as it sits, it contracts also, so as to make it appear much shorter; its legs and feet are of a dusky brown; it has a very loud and shrill voice; its head, neck, back, wings, and tail, are all of a brownish-black, with a faint admixture of green; the lower part of the throat, the breast, and the belly, are yellow, the upper part of the throat white; its beak is very sharp-pointed. See LANIUS *Pitangua*.

PITCAIRN, ARCHIBALD, in *Biography*, an eminent physician of the mechanical school, was born at Edinburgh on the 25th of December, 1652. Having received the early part of his education at a private school at Dalkeith, he was removed to the university of Edinburgh; where, having gone through a course of philosophy, he first studied divinity, and then civil law. In consequence of his intense application his health began to suffer, and symptoms of pulmonary consumption appeared, for the removal of which he was advised to travel to Montpellier in France. His health was speedily re-established, and he determined to pursue the study of the law in that university. He found, however, that there was no able professor of that subject in Montpellier; and as he associated with several of his countrymen, who were studying physic, he was induced to change his purpose again, and adopted their pursuit. On returning to Edinburgh, thus prepared with the first elements of all the three learned professions, but undetermined which to follow, he applied himself zealously to the mathematics, in which he made great progress without a master, and was thus led, by discovering, as he supposed, the applicability of mathematical reasoning to medicine, to adopt the latter as his profession.

After studying diligently for some time the collateral branches of medicine, botany, pharmacy, and the materia medica, at Edinburgh, he went again to Paris, where he completed his medical studies, and then settled in Edinburgh, a little before the revolution, where he quickly obtained a great share of practice and an extensive reputation. In 1688, he published a little tract, entitled "Solutio Problematis de Inventoribus," the object of which was to ascertain Harvey's right to the discovery of the circulation of the blood. His extending reputation obtained for him, in 1692, an invitation from the curators of the university of Leyden to the professorship of physic in their school. He accepted this honourable appointment, and made his inaugural speech from the chair, on the 26th of April in that year: the afterwards celebrated Boerhaave was one of his pupils. His new method of teaching the principles of phyfiology and pathology on mathematical principles, was, however, not very intelligible by the ftudents, and met with confiderable oppofition from the members of the faculty; infomuch that, after refiding about a year, during which fhort fpace he publifhed feveral differtations illuftrative of the advantages of applying mathematical principles to medicine, he quitted Leyden rather unceremonioufly, deferting a chair, in which he had found himfelf fomewhat neglected.

On his return to Scotland in 1693, he married the daughter of fir Archibald Stephenfon, an eminent phyfician in Edinburgh, and was induced again to fettle there, when he wrote a valedictory letter to the univerfity of Leyden. His lady did not furvive her marriage many years; but fhe brought him a daughter, who was afterwards married to the earl of Kelly. Dr. Pitcairn died at Edinburgh on the 13th of October, 1713.

In 1701, Dr. Pitcairn republifhed the Differtations which he had formerly printed, together with fome additional ones; they were dedicated to profeffor Bellini of Pifo, who had adopted the mathematical doctrines of phyfiology, and had paid a fimilar compliment to him in his Opufcula. This edition was publifhed in 4to. at Rotterdam, under the title of "Difputationes Medicæ," and contains eight effays. The laft edition, which appeared during his life, was publifhed at Edinburgh, a few months before his death, under the fame title; but they were reprinted in 1714 at Rotterdam, and in 1715 at Venice, under the title of "Opufcula Medica." After his death, his lectures to his pupils were publifhed, under the title of "Elementæ Medicinæ Phyfico-Mathematica," Lond. 1717; and in an Englifh tranflation in 1727. All his works have been collected and printed together at Venice, 1733, and Leyden, 1737, in 4to. Pitcairn ufed to amufe himfelf occafionally with writing Latin poetry, for which he had no mean talent; and a few of his compofitions in this way were printed, with the title of "Poemata Selecta," which are chiefly of the epigrammatic kind. Eloy Dict. Hift. de la Medecine. Hutchinfon, Biographia Medica.

Pitcairn's *Ifland*, in *Geography*, an ifland in the South Pacific ocean, fo called by captain Carteret in 1767, after a young gentleman, fon to major Pitcairn of the marines, who was loft in the Aurora, and who had difcovered it. Upon approaching it, it appeared like a great rock rifing out of the fea, not more than five miles in circumference, and feeming to be uninhabited. It was neverthelefs covered with trees, and a ftream of frefh water was obferved to run down one fide of it. A number of fea birds hovered round it, and the adjoining fea feemed to have fifh. It is feen at the diftance of more than fifteen leagues, and lies about a thoufand leagues W. of the continent of America, in S. lat. 25° 2′. W. long. 133° 21′.

PITCAIRNIA, in *Botany*, received that name from M. l'Heritier, in honour of the late William Pitcairn, M. D. F. R. S. Prefident of the College of Phyficians, and a truftee of the Britifh Mufeum; one of the moft amiable and benevolent of men, who employed the leifure of the extenfive medical practice, to which his long life was devoted, to the cultivation of a botanic garden at Iflington. There he entertained his friends, and communicated his fcientific riches, with the fame liberality with which he beftowed the moft valuable charity of his medical advice, on thofe who ftood in need of it. In conjunction with the no lefs diftinguifhed Fothergill, Dr. Pitcairn fent a perfon to collect on the Alps of Switzerland, many curious plants, previoufly unknown to Englifh cultivators, the great number of which acquifitions may be feen in the Hortus Kewenfis of the late Mr. Aiton and his fon. The name of *Hepetis*, appropriated by Swartz, from Solander's manufcripts, to this fame genus, has by common confent been given up, in favour of the claims of fo eminent a benefactor to botany as Dr. Pitcairn.—L'Herit. Sert. 7. Ait. Hort. Kew. ed. 1. v. 1. 401. ed. 2. v. 2. 201. Mart. Mill. Dict. v. 3. Swartz Ind. Occ. 578. Willd. Sp. Pl. v. 2. 10. Lamarck Illuftr. t. 224. (Hepetis; Swartz Prodr. 56. Schreb. 798.)—Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Bromeliæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, in three deep, lanceolate, equal fegments, converging into a tube, permanent, its bafe adhering to the lower half of the capfule. *Cor.* Petals three, oblong, twice the length of the calyx, cohering in the form of a tube, withering. Nectary a fcale at the bafe of each petal. *Stam.* Filaments fix, thread-fhaped, fhorter than the corolla, inferted into the bafe of the calyx; anthers erect, linear-arrow-fhaped. *Pift.* Germen fuperior, ovate, with three furrows; ftyle thread-fhaped, the length of the ftamens; ftigmas three, twifted together. *Peric.* Capfule ovate, pointed, three-lobed, with three longitudinal furrows, three cells, and three valves; the partitions from the inflexed valves, foon feparating at the upper part. *Seeds* numerous, minute, oblong, winged.

Eff. Ch. Calyx in three deep fegments, inferior, permanent. Petals three, with a fcale at the bafe of each. Stigmas three, twifted together. Capfule of three lobes, burfting at their inner edge. Seeds winged.

1. P. *bromeliæfolia*. Scarlet Pitcairnia. L'Herit. Sert. t. 11. Ait. n. 1. Willd. n. 1. Curt. Mag. t. 824. Schneevoght Ic. t. 11. Redout. Liliac. t. 75.—Leaves fringed with fpinous teeth. Flower-ftalks fmooth, equal to the calyx, longer than the bracteas.—Native of Jamaica, on the fides of fhady rocky precipices, where it flowers in the middle of fummer. *Swartz.* It was brought to England before 1781, and is readily increafed in the ftove by offsets. *Root* perennial, of numerous long ftout fibres. *Stem* none. *Leaves* numerous, radical, fheathing, fpreading, very long, linear, taper-pointed, channelled, keeled, fmooth, moft glaucous, beneath an inch wide; their edges a little recurved, fringed with numerous fpinous teeth, efpecially the outermoft; the inner ones are often deftitute of teeth, particularly upwards. *Stalk* central, radical, erect, two or three feet high, round, bearing a few toothed *bracteas*, or fmall leaves, occafionally at the bottom, the upper part racemofe, fomewhat pyramidal, fometimes branched, many-flowered. Partial *ftalks* alternate, horizontal, fimple, fingle-flowered, fmooth, an inch long. *Bracteas* folitary at the bafe of each partial ftalk, lanceolate, taper-pointed, coloured, fhorter than the ftalk, permanent. *Flowers*, as well as their common and partial *ftalks*, and *bracteas*, of a beautiful rofe-colour approaching to fcarlet. *Calyx* an inch long, quite fmooth. *Petals* more than twice as long, withering and fading quite in a different manner from the calyx. *Capfule* the length of the calyx, with long-pointed valves.

2. P. *anguftifolia*, Narrow-leaved Pitcairnia. Ait. n. 2. Willd. n. 2. Redout. Liliac. t. 76. Curt. Mag. t. 1547. —Leaves fringed with fpinous teeth. Flower-ftalks downy, longer than the downy bracteas. Calyx downy at the bafe, twice the length of the flower-ftalks.—Native of the ifland of Santa Cruz, where it was difcovered by Mr. Ryan, and fent by him to Kew in 1777. It flowers in the ftove in winter. This has narrower and more fpinous *leaves* than the former; much fhorter downy partial *ftalks* and *bracteas*. *Flowers* variable in colour, at leaft in our gardens, according to the greater or lefs portion

tion of sunshine, from rose-colour or scarlet to pale yellow. See the Botanical Magazine.

3. P. *latifolia*. Broadish smooth-leaved Pitcairnia. Ait. n. 3. Willd. n. 3. Andr. Repos. t. 322. Curt. Mag. t. 856, excluding the synonym of Redouté.—Leaves entire; slightly spinous at the base. Flower-stalks smooth, half the length of the smooth calyx.—Native of the West Indies. The *leaves* are really not broader than those of the *bromeliæfolia*, but are distinguished from that, as well as from *angustifolia*, by being quite smooth and entire at the edges, except a few short crowded teeth at the very bottom. The *flowers* are either scarlet, or pale rose-coloured. *Bracteas* smooth, variable in length, sometimes equal to the partial *stalks*, sometimes much shorter. *Calyx* twice or thrice as long as its partial *stalk*, and, like that, quite smooth. Mr. Anderson, the very ingenious and scientific gardener of James Vere, esq. of Kensington Gore, has remarked, that this plant may be made to blossom best, by leaving it on the shelf of the dry stove, till the bud appears; after which the pot should be plunged into the bark bed. The *flowers* are usually produced in July or August.—We have a specimen of this species with a few spinous teeth on one leaf, towards the top. Its *bracteas* are woolly on their inner, or upper, surface; quite smooth beneath.

4. P. *bracteata*. Great Spiked Pitcairnia. Ait. n. 4. (P. latifolia; Redout. Liliac. t. 73, 74. P. sulphurea; Andr. Repos. t. 249.)—Leaves entire; slightly spinous at the base. Flowers nearly sessile, crowded. Bracteas as long as the calyx.—Native of the West Indies. It seems to have flowered first in the choice collection of Mr. Evans, of Stepney. Mr. Woodford, late of Vauxhall, sent it to the French gardens. This is a very striking species, whose *leaves* most agree with the last, with which it has been confounded. It differs from that, and every other species, in its dense *spike* of very numerous, crowded, nearly sessile *flowers*, accompanied by large *bracteas*, reaching as far as the points of the *calyx*. The *corolla* is either scarlet, or pale yellow; the latter seems to be occasioned by its coming out in spring, rather than in summer or autumn.

PITCH, in the *Arts*, a resinous substance, which is the residuum of the distillation of tar. Resin differs from pitch in being the residuum of turpentine, which is obtained from the different species of pine without heat. Tar is obtained by cutting the wood into pieces, and exposing it to the heat by a furnace for the purpose. This accounts for the blackness of the latter, arising from the decomposition of the essential oil by heat. Hence the spirit of tar differs from the spirit of turpentine merely in colour, from the presence of carbonaceous matter. See TAR and TURPENTINE.

Pitch is properly a juice of the wild pine, or pitch-tree; and is conceived to be no other than the oil thereof inspissated, and turned black, farther than in the balsam. For the method of procuring it from the wood of this tree, see PINE. See also TURPENTINE.

The best is that brought from Sweden and Norway. Its goodness consists in its being of a glossy black colour, dry, and brittle.

This is less pungent and less bitter than the liquid tar, (see TAR,) and used only in some external application, as a warm, adhesive, resinous substance. Neumann observes, that when melted with oils, resins, and fats, into ointments and plaster, the pitch is very apt to separate and precipitate. The ancients had a peculiar kind of pitch called *brutia*, which was inspissated to a higher than ordinary degree for certain uses; such as the receiving a proper quantity of bees' wax, to render it the zopissa used in coating the bottoms of ships; which the common pitch could not do, being of too soft a consistence for this use. Pliny tells us that it was made in this manner: the wood was cleaved and formed into a pile, with proper trenches cut in the earth to receive what run from it in burning. When the pile was lighted, the first thing that flowed into these trenches was a thin fluid liquor like water. Lamp black is the soot of burned pitch: and it is likewise prepared by collecting the soot of pit-coal. See *Lamp* BLACK.

PITCH, *Burgundy*, is brought to us from Saxony, and is supposed to be a preparation of the same kind with the common resin of the shops, only less divested of the oil, made by boiling the common turpentine till it acquires a due consistence. Upon making an incision into the bark of the "Pinus abies," or Norway spruce fir-tree, a clear tenacious fluid issues, which concretes into a resinous substance, known by the name of "resina abietis." This, after being boiled in water, and strained through a linen cloth, is called in the Pharmacopeias "Pix Burgundica," or Burgundy pitch. But if the boiling of the native resin is continued till the water is wholly evaporated, and wine vinegar is at this time added, a substance of the name of "Colophonium" is formed. The greatest quantity of Burgundy pitch is collected in the neighbourhood of Neufchatel, whence it is brought into this country packed in casks. A fictitious sort is made in England, and found in the shops under the title of *common* Burgundy pitch. It may be distinguished by its friability, want of viscidity and unctuosity, and the odour which characterises the genuine sort. Burgundy pitch is of a solid consistence, yet somewhat soft, of a reddish-brown colour, and not disagreeable in smell. It is entirely confined to external use, and was formerly an ingredient in several ointments and plasters. In inveterate coughs, affections of the lungs, and other internal complaints, plasters of the resin, by acting as a topical stimulus, are frequently found of considerable service. See PLASTER.

PITCH, *Jews'*. (See BITUMEN.) Jews' pitch, or asphaltes, is black, brilliant, ponderous, and very brittle. It emits a smell by friction; and is found floating on the water of the lake Asphaltites, or the Dead sea. The asphaltes of commerce is extracted from the mine of Annemora, and more particularly in the principality of Neufchatel. M. Pallás found springs of asphaltes on the banks of the Sock, in Persia. Most naturalists, says Chaptal, consider it as amber, decomposed by fire. It liquefies on the fire, swells up and affords flame, with an acrid disagreeable smoke. By distillation it affords an oil resembling petroleum. The Indians and Arabs use it instead of tar; and it is a component part of the varnish of the Chinese.

PITCH, *Mineral*. (See BITUMEN.) This is a modification of pretroleum. It is found in France, in Auvergne, at a place called Puits de Lapege, near Allais, over an extent of several leagues. The calcareous stone is impregnated with a bitumen, which is softened by the heat of summer, when it flows from the rocks, and forms a very beautiful stalactites. It forms masses in the fields; and impedes the passage of carriages: the peasants use it to mark their sheep. This stone, when rubbed, emits a filthy smell. Some have asserted that mineral pitch was used to cement the walls of Babylon.

PITCH, *Naval*, *pix navalis*, is that drawn from old pines, ranged and burnt like charcoal. This, with a mixture of tow, or beaten cables, serves for paying over the seams of a ship's sides and decks, after they are caulked, to preserve the oakum from any wet; and likewise over all the surface of the bottom and wales: to pay the two latter it is softened with oil.

PITCH, *Naval*, is also a denomination given to that scraped from

from off the ſides of old veſſels; and which is ſuppoſed to have acquired an aſtringent virtue, by means of the ſalt water. It ſerves to make plaſters; though it is certain the apothecaries uſually ſubſtitute the common black pitch in its ſtead.

Pitch, *Greek*, or *Spaniſh pitch*, is that boiled in water till it has loſt its natural ſmell; upon which it becomes dry and friable.

The ancients called it *colophony*; from Colophon, a city in Greece, whence great quantities were brought. See Colophon, and *Burgundy* Pitch, ſupra.

Pitch, *Oil of*, *oleum picinum*, is an oil procured from pitch, by ſeparating the aqueous matter that ſwims a-top of the melted pitch. This, from the great virtues formerly attributed to it, was alſo called *balſam of pitch*.

Pitch, *Ointment of*, is made by melting tar with an equal weight of mutton ſuet, and ſtraining the mixture whilſt hot: this is uſed ſometimes as a digeſtive, and ſaid to be particularly ſerviceable againſt ſcorbutic and other cutaneous eruptions. See Tar.

Pitch, *Pills of*, are made of tar mixed with ſo much powdered liquorice, or other ſuch powdered matter as is ſufficient to render it of due conſiſtence for being formed into pills. See Tar.

Pitch *of Caſtro*, in the *Materia Medica*, the name given by Boccone and ſome other writers to a thick kind of bitumen, found iſſuing out of the cracks of ſome rocks near the village of Caſtro: from whence it has its name: it is famous in the eccleſiaſtical ſtate for its medicinal virtues.

Pitch, in *Building*, denotes the angle or gable end.

If the length of each rafter be three-fourths of the breadth of the building, the roof is ſaid to be *true* pitch. This is uſed when the covering is of plain tiles.

If the rafters be longer, it is ſaid to be a *high* or *ſharp-pitched* roof; if ſhorter, which ſeldom happens, it is ſaid to be a *low* or *flat-pitched* roof.

If the length of the principal rafters be equal to the breadth of the building, it is called *Gothic* pitch. This is uſed when the covering is of pantiles.

If to rule as a pediment, it is ſaid to be *pediment* pitch. The perpendicular height of this pitch, is equal to $\frac{2}{9}$ths of the breadth of the building. This pitch is uſed when the covering is lead.

Pitch, in *Muſic*, implies the elevation or depreſſion of the general ſcale. There is no term more common among muſicians,—who have the Roman pitch, the opera pitch, the organ pitch, the concert pitch. By the firſt is underſtood a *low* pitch; by the ſecond, the *true* and moſt general pitch; by the third, a *high* pitch; as almoſt all church organs are pitched very high by the builders, we believe, to ſave metal; of which more is neceſſary for a long than a ſhort pipe of the ſame diameter: and by the fourth, a varied pitch, according to the ſtate an inſtrument is found in by perſons who had never met before.

To Pitch *a Camp*, in *Military Language*, ſignifies to take a poſition, and encamp troops upon it according to the principles of *caſtrametation*; which ſee. See alſo Camp.

To Pitch *a Tent*, is to place a certain preſcribed quantity of canvas upon poles, ſo as to afford a temporary cover againſt the inclemency of the weather, for one or more officers or private ſoldiers. In order that the men may be expert in pitching or ſtriking tents, they ſhould be practiſed whilſt in camp in both operations.

Pitch, in *Rural Economy*, a fork full of hay, corn, or ſtraw, or as much as is raiſed to the load, ſtack, or mow, at one time.

Pitch-*Fork*, a ſort of fork with two prongs, which is in uſe for pitching different ſubſtances, as hay, corn, ſtraw, &c., to the cart, mow, ſtack, or other places; and which is uſually made larger and longer in the handle than the common hay fork.

Pitch-*Ore*, in *Mineralogy*, a ſpecies of the genus Uran, is of a velvet-black colour, or dark greyiſh-black, which inclines to iron-black. It occurs generally maſſive, and diſſeminated: internally it is ſhining, inclining to gliſtening, and its luſtre is reſinous. The fracture is imperfect and flat: the fragments indeterminately angular, and ſharp-edged. It occurs ſometimes in thick and curved lamellæ; ſometimes in coarſe and diſtinct concretions, reſembling red hematite. In the ſtreak, neither colour nor luſtre is changed. It is ſoft, brittle, and heavy. The ſpecific gravity is variouſly given: by Guyton it is ſaid to be 6.38; by Haüy, 6.53; and by Klaproth it is ſaid to be 7.5. It is infuſible, without addition, before the blowpipe. With ſoda or borax it forms a grey, muddy, ſlaggy-like globule; with phoſphoric ſalts it makes a tranſparent green bead. It diſſolves imperfectly in the ſulphuric or muriatic acids, and from this ſolution, which has a pale orange-yellow colour, the uran is precipitated browniſh-red by pruſſiat of potaſh, and yellow by the alkalies. According to Klaproth its conſtituent parts are,

Uran	86.5
Black oxyd of iron	2.5
Sulphurated lead	6.0
Silica	5.0
	100.0

By the analyſis of other chemiſts it is ſaid to contain only uran and iron, but neither ſulphurated lead nor ſilica; and in another ſpecimen were found ſulphur and a ſmall portion of copper. It is found in veins in primitive mountains with lead and ſilver ores. It is uſually accompanied with lead-glance, copper-pyrites, iron-ochre, calc-ſpar; ſometimes with cobalt-glance, red cobalt-ochre, ſilver-glance, uran-mica and uran-ochre. It is found in ſeveral parts of Saxony, Bohemia, and Norway, and is diſtinguiſhed from brown-blende by colour, ſpecific-gravity, fracture and ſtreak; from wolfram, by its ſtreak and fracture.

Pitch-*Tree*, in *Botany*. See Pine-*Tree* and Pinus.

PITCHED, in *Sea Language*. They ſay the maſt is pitched, when it is put or let down into the ſtep; alſo the maſt is pitched too far aft, when placed too near the ſtern. When a ſhip falls with her head too much into the ſea, or beats againſt it ſo as to endanger her top-maſts, they ſay, ſhe will *pitch her maſts by the board*.

This motion may proceed from two cauſes; the waves which agitate the veſſel, and the winds upon the ſails, which make her ſtoop to every blaſt thereof.

PITCHER, in *Agriculture*, the labourer or perſon who is employed in pitching.

PITCHET, in *Geography*, a town of Upper Siam; 40 miles S. of Porſeloue.

PITCHIN, a town of Perſia, in the province of Mekran; 100 miles W. of Kidge.

PITCHING. See Pavement.

Pitching, in *Seamanſhip*, the inclination or vibration of the ſhip lengthwiſe about her centre of gravity; or the motion by which ſhe plunges her head and after-part alternately into the hollow of the ſea. This is a very dangerous motion, and when conſiderable, not only retards the ſhip's way, but endangers the maſts and ſtrains the veſſel. This motion proceeds from two cauſes; *viz.* from the veſſel's improper conſtruction, or the ill arrangement of her cargo. See Shipbuilding.

Pitching-*Pence*, a duty, commonly of one penny, paid for pitching or fetting down every fack of corn, or pack of merchandize, in a fair or market.

PITCHSTONE, in *Mineralogy*, a fpecies of the clay genus, of which the colours are black, green, brown, red, and fometimes, but rarely, grey. Of the black, there are the greenifh, greyifh, and brownifh-black. From greenifh-black it paffes through blackifh-green into mountain-green, afparagus-green, leek-green, olive-green, and oil-green. From olive-green it paffes into liver-brown, yellowifh and reddifh-brown, and again into light-blood and brick-red. The varieties of the grey are fmoke and dark afh-grey, and fometimes a kind of grey which paffes into brown. It has fometimes a blueifh colour. Its colours are not lively, but always fomewhat deep and muddy, or rather mixed with grey and brown. It is generally uniform, and it feldom happens that feveral colours occur together. It is found almoft always maffive, in great beds and rocks. Internally its luftre is fhining, fometimes fplendent, fometimes gliftening, and intermediate between refinous and vitreous, yet more inclining to the firft. The fracture paffes from the large conchoidal into the coarfe fplintery and coarfe grained uneven. The fragments are indeterminately angular, more or lefs fharp-edged. It occurs fometimes in coarfe diftinct concretions, and the furface of the concretions is fomewhat bent; alfo in prifmatic generally wedge-fhaped diftinct concretions, of which the furface is fmooth. It is commonly tranflucent in a fmall degree; the black variety is only tranflucent on the edges. It is brittle; eafily frangible, and not very heavy. The fpecific gravity of the Saxon pitchftone is about 2.3. Before the blowpipe it is fufible without addition. The black variety, heated to 21° of Wedgewood's pyrometer, fwelled a little, its colour was flightly altered, the furface glazed, and internally it was porous; at 31° it was foftened; at 65°, the intumefcence was more confiderable; and at 100° it was ftill veficular, but more compact. The blackifh-green variety found at Arran becomes black, is much rent, and internally porous at 23°; at 55° it formed a porous enamel; at 70° it became perfectly white and ftill porous. The pitchftone of Meiffen, by analyfis, gave of

Silica	73.00
Alumine	14.50
Lime	1.00
Oxyd of iron	1.00
Oxyd of manganefe	0.10
Natron	1.75
Water	8.50
	99.85
Lofs	15
	100.00

It occurs in beds in the newer porphyry formations, and in beds and veins that belong to the neweft flotz trap formation. It is found in great quantity in the electorate of Saxony, particularly in the neighbourhood of Meiffen, alfo in Hungary, as at Tokay and Schemnitz; in fome of the iflands of the Archipelago, where it was firft obferved by Mr. Hawkins; and at Glamofcard in the ifland of Skye. It was firft difcovered about fixty years ago in the neighbourhood of Meiffen in the electorate of Saxony, and was named pitchftone from the ftriking refemblance which feveral of its varieties bear to pitch.

PITCHT, Shoulder. See Shoulder *Pitcht*.

PITCHY *Iron-Ore*, in *Mineralogy*, a metallic foffil, of a very deep reddifh-brown, which fometimes paffes into black. It occurs maffive with a rough furface, owing to a covering of iron-ochre. Internally it is gliftening, and its luftre is femi-metallic, paffing into refinous. The fracture is compact, and fometimes foliated. It is opaque, not eafily frangible, and brittle. Its fpecific gravity is nearly 4. It melts very eafily into a black enamel before the blowpipe; and its conftituent parts are, phofphoric acid, oxyd of iron, and oxyd of manganefe. It is found at Limoges in France.

PITEA, or Pithea, in *Geography*, a fea-port town of Sweden, in Eaft Bothnia, fituated on a fmall ifland at the mouth of a river of the fame name: joined to the continent by a wooden bridge. The ftreets are parallel, and the church is at a confiderable diftance from the town. It has a commodious harbour and a good fchool. It was firft built in 1621 by Guftavus Adolphus, three miles from its prefent fcite higher in the country; but in 1666 this town was deftroyed by fire, and the prefent town was built in its prefent fituation. N. lat. 65° 23′. E. long. 21° 22′.

PI-TEOU, a fmall ifland near the coaft of China. N. lat. 25° 20′. E. long. 119° 14′.

PITESZTI, a town of Walachia; 50 miles N.W. of Buchareft. N. lat. 44° 57′. E. long. 24° 49′.

PITH, in *Vegetable Phyfiology*. See Medulla.

PITHECALOPEX, the *Semivulpa*, or *Ape-fox*, in *Zoology*, a name given by Aldrovandus and fome others to that ftrange American animal which we call the opoffum.

The name is compounded of that of the fox and the ape; of the natures of both which animals it is fuppofed by fome to participate.

PITHECON Portus, in *Ancient Geography*, a port of Africa, in Libya, near Carthage.

PITHECUSSÆ, iflands of the Tyrrhenian fea, near the coafts of Campania.

PITHIAS, or Pithites, with fome writers, a fort of comet, or rather meteor, in form of a tub. Of thefe it is faid there are divers kinds, *viz.* fome of an oval figure, others like a tun or barrel fet perpendicular, and fome like one inclined or cut fhort off; others having a hairy train or bufh, &c.

PITHING, the name of an operation performed for killing animals fuddenly and without pain. This is effected with a narrow doubled-edged poniard paffed in between the fkull and firft vertebra of the neck: in this way the medulla oblongata is divided, and the animal inftantaneoufly deprived of fenfibility. This operation was performed by Mr. Cline junior, affifted by Mr. Brodie and Mr. Clift, on a camel that had been the fubject of Mr. Home's experiments. (See Phil. Tranf. vol. xcvi. p. 359.) In the common mode of pithing cattle, the medulla fpinalis only is cut through, and the head remains alive, which renders it the moft cruel mode of killing animals that could be invented. See Dr. Dugard's Experiments, publifhed in the Board of Agriculture's Report for Shropfhire, by Jofeph Plumley, M. A. p. 246.

PITHIVIERS, in *Geography*, a town of France, and principal place of a diftrict, in the department of the Loiret; 21 miles E.N.E. of Orleans. The place contains 3071, and the canton 15,275 inhabitants, on a territory of 302½ kiliometres, in 22 communes. N. lat. 48° 11′. E. long. 2° 24′.

PITHOU, Peter, in *Biography*, a magiftrate diftinguifhed for his integrity and erudition, was born in 1539 at Troyes, in Champagne. He received a good education, after which he ftudied the law as a profeffion. When called to the bar his natural diffidence fo completely embarraffed him, that he found it neceffary to renounce that branch of his profeffion. Being of the reformed religion he had nearly been facrificed

facrificed at the horrid maffacre of St. Bartholomew's day, which probably had fuch an effect upon his mind, naturally timid, that in the following year he conformed to the Catholic church, and foon after obtained the office of attorney-general in the chamber of juftice in Guienne. When Gregory XIII. had iffued a brief againft the ordinance of Henry III., concerning the council of Trent, Pithou publifhed a memoir, in which he developed the fecret purpofes of the brief, and vigoroufly defended the caufe of his king and country. After Henry IVth's converfion, as it has been called, he ufed his beft endeavours to reduce the city of Paris to allegiance. He was one of the writers of the "Catholicon d'Efpagne," a fatire which proved very effectual in throwing ridicule upon the Spanifh party. He alfo publifhed a little work, which he pretended was a tranflation from the Italian, entitled "Raifons pour lefquelles les Evêques de France ont pu de droit donner l'Abfolution à Henry de Bourbon," which was feveral times printed, and which made many converts to the royal caufe. He died in the year 1596, at the age of 57. He is reprefented by De Thou as one of the firft men of the age, as well for probity, candour, and real piety, as for the extent of his learning, the foundnefs of his judgment, and his political wifdom. He had a moft intimate acquaintance with every thing relative to French hiftory and antiquities, and his profound knowledge of the civil law, in which he was fcarcely inferior to Cujas himfelf, under whom, in his youth, he had ftudied. The works of this gentleman are, "Traité des Libertès de l'Eglife Gallicane," in four vols. folio, and which is thought to be the bafis of all that has been written on the fame fubject: "A commentary on the Cuftoms of Troyes," and other tracts on civil and canonical jurifprudence. He publifhed, in 1609, a large collection of "Opufcules," alfo editions of feveral monuments of antiquity, chiefly relating to the hiftory of France. He had collected a curious and very valuable library, rich in MSS., which by his will he directed to be fold only to a fingle purchafer acquainted with its value; this precaution, however, did not prevent its difperfion. By his deep and extenfive erudition he acquired the title of the French Varro, and his name was not lefs celebrated abroad than in his own country. Gen. Biog.

Pithou, Francis, brother of the preceding, born in 1544, was likewife brought up to the law, and exercifed the office of attorney-general to the chamber of juftice, eftablifhed by Henry IV. to check the frauds of the financiers. He affifted at the conferences of Fontainebleau, and was one of the commiffioners for regulating the boundaries between France and the Low Countries. After this he retired, paffing his life in ftudy, emulating his brother in the variety and depth of his learned refearches. He died in 1621. He took a part in moft of his brother's publications, and efpecially contributed to the elucidation of the "Body of Canon Law," printed at Paris, in two vols. fol. He was author likewife of feveral works, of which the chief are, "La Conference des Lois Romaines avec celles de Moyfe;" an edition of the "Salic Law," with notes; "Traité de la Grandeur et Droits du Roi et du Royaume de France." He publifhed an edition of the "Antiqui Rhetores Latini," 1599. He difcovered "Phædrus' Fables," which he publifhed in conjunction with his brother. The names of the two brothers are very celebrated among men of letters. A full and exact catalogue of their feveral publications is prefixed to their works in Latin, printed in 1715. Moreri.

PITHYUSA, in *Botany*, a name ufed by many authors for a fmall fpecies of fpurge.

PITI, in *Geography*, a town of Thibet; 204 miles S. of Latac.

PITIES, in *Commerce*, the only money of the natives of the ifle of Java, which is a fmall coin containing four parts of lead and one of tin; 25 of thefe pafs for two duyts, each duyt being a fourth part of the copper coin, called the ftiver.

PITIGLIANO, in *Geography*, a town and fortrefs of Etruria; 23 miles E.N.E. of Orbitello.

PITIHEMPO, a mountain of Afia, which bounds Thibet to the north-weft.

PITINUM, in *Ancient Geography*, a town of Italy, in the territory called by Pliny "Pitinas Ager," on the other fide of the Apennines, and watered by the river Novanus. Ptolemy affigns this town to the Umbrians who inhabited the territory N. of the Tufcans.

PITISCUS, Samuel, in *Biography*, a learned philologift, was born at Zutphen in 1637. He ftudied under J. Fr. Gronovius at Deventer, and afterwards went through a courfe of theology at Groningen. When he had completed his education, he was made mafter of the fchool at Zutphen, and, in 1685, he was promoted to be rector of the college of St. Jerom at Utrecht. He died at a very advanced age at Utrecht, in the year 1717. He was author of "A Latin and Dutch Dictionary;" but his principal work was "Lexicon Antiquitatum Romanarum," in two vols. fol. the labour of ten years of his life; a performance well known to the learned world. He alfo gave a new and improved edition of the "Roman Antiquities" of Rofin, and of Pomey's "Pantheon Myfticum."

PITIVILCO *la Baranca*, in *Geography*, a town of Peru, in the diocefe of Lima; 28 miles N.N.W. of Guaura.

PITKEATHLY or Pitcaithly, a village in the parifh of Dumbarny, and county of Perth, Scotland, is feated in a fequeftered corner of the rich vale of Stratherne, at the diftance of four or five miles from Perth. It has been long celebrated for its mineral fprings, and of late years has become a place of very fafhionable refort. In the efficacy of the waters for the cure of fcrofula, fcurvy, gravel, and complaints in the ftomach and bowels, Pitkethly wells are generally confidered equal, if not fuperior, to any in North Britain; and the village yields to none in beauty and agreeablenefs of fituation. There are here five diftinct fprings of different degrees of ftrength, but all partaking of the fame qualities. The chief mineralizers are muriate of foda (common falt) and muriate of lime, with a portion of chalk and Paris plafter held in folution. An account of thefe waters, and of their medicinal ufes, was publifhed in the 62d volume of the Philofophical Tranfactions. The period of their difcovery cannot be afcertained; as even tradition is filent upon the fubject.

The parifh of Dumbarny is about four miles in length and three in breadth. The foil is extremely fertile, and the furface finely diverfified with level and rifing grounds, wood, and water. The river Earn runs through the middle of the parifh; and on one fide it is bounded by the hill of Mordun or Moncrieff, the view from which is characterifed by Pennant as "the glory of Scotland." The bridge over the Earn here is of great antiquity, and is kept in repair by the magiftrates of Perth. Carlifle's Topographical Dictionary of Scotland, vol. i. 4to. Beauties of Scotland, vol. iv.

PITLAND, a town of Hindooftan, in Guzerat; 18 miles N.E. of Cambay.

PITLAR, a town of Ruffia, in the government of Tobolfk; 48 miles S. of Obdorfkoi.

PITLAWAD, a town of Hindooftan, in the circar of Banfwalch; 12 miles S. of Tandla.

PITOE, a town Thibet; 24 miles W.N.W. of Latac.

PITON Point, the S.W. point of the island of St. Lucia.

PITOT, Henry, in *Biography*, a mathematician and engineer in the 18th century, was descended of a noble family of Languedoc, and born in the year 1695. His genius inclining him to the mathematical sciences, he made himself a proficient in them without the aid of a tutor. At the age of twenty-three he went to Paris, and became intimately acquainted with Reaumur. In 1724 he was received into the Academy of Sciences, of which he was elected a pensioner not many years afterwards. He was author of a highly esteemed work, entitled "The Theory of working Ships," 1731, which was so highly esteemed, that on account of it, he was elected a member of the Royal Society of London. In 1740, the states-general of Languedoc gave him the appointment of principal engineer to the province, and also that of inspector-general of the famous canal, which forms a navigable junction between the Mediterranean sea and the bay of Biscay. "Many monuments of his genius," says his biographer, "which will transmit his name with honour to posterity, may be seen in different parts of Languedoc; and, in particular, a noble plan designed and executed by him for supplying Montpelier with water from sources at the distance of three leagues, which has deservedly excited the admiration of travellers. Out of respect to his merits, the Royal Academy of Sciences at Montpelier inscribed his name in the list of their members, and the king honoured him with the order of St. Michael." He died in 1771, at the age of 76, esteemed for his probity and disinterestedness, and highly respected for his science and ingenuity.

PITQUIN, in *Geography*, a town of New Mexico, and capital of the province of Sonora; 900 miles N.W. of Mexico. N. lat. 29° 56′. W. long. 112° 12′.

PITRIOWIN, a town of Austrian Poland, in Galicia; 32 miles S.W. of Lublin.

PITRIPETI, in *Mythology*, a name of the Hindoo deity Yama, who corresponds with the Pluto of western mythologists. See Yama.

PITRIS, a class of beings with the Hindoos, to whom reverence is paid in their sacrificial ceremonies. They sometimes seem to bear the character of patriarchs, or sages of former days, and at others the moon is assigned for their habitation. The word often occurs in Hindoo books, but apparently without any precise signification attached to it. In the institutes of Menu, they are thus described. "The Pitris, or great progenitors, are free from wrath; intent on purity; ever exempt from sexual passions; endued with exalted qualities: they are primeval deities, who have laid arms aside." "From the Rishis come the Pitris, or patriarchs," &c. ch. iii. v. 192. 200. See Rishis.

PITSCHEN, or Bitschen, in *Geography*, a town of Silesia, in the principality of Brieg; surrounded with walls, and containing two churches and a college; 30 miles N.E. of Brieg. N. lat. 51° 8′. E. long. 18 15′.

PITSHAN, a town of Little Bucharia; 30 miles E.N.E. of Tourfan.

PITSYLVANIA. See Pittsylvania.

PITT, Christopher, in *Biography* an English poet, son of a physician, was born at Blandford, in Dorsetshire, in the year 1699. He was educated in Winchester school, where he was distinguished for his assiduity in study, for his taste as a general scholar, and as a writer of English verse. On leaving Winchester, he was elected to New college, Oxford, and as an acknowledgement of the kindness of the electors, he presented them with two manuscript volumes of poems, of which one was miscellaneous, and the other contained a complete version of Lucan's Pharsalia. He was intended for the church, and after three years residence at college, he was presented, in 1722, to the rectory of Pimpern, in Dorsetshire, to which place he retired after a further continuance of two years at Oxford, when he had taken his degree of M.A. Here he passed the remainder of his life in an easy situation, maintaining a social and very friendly intercourse with many persons of rank and literary eminence. He died in 1748, in the 49th year of his age, generally respected and beloved. In 1727, he published a volume of Miscellaneous Poems; after which he produced a translation of Vida's Art of Poetry, which possesses much of the elegance and high polish of the original. His success in this department of literature encouraged him to undertake the task of translating Virgil's Eneid, which he completed in 1738, and published in two vols. 4to. in 1740. "This translation," says his biographer, "if Dryden's had not existed, would have been considered as a very valuable addition to the mass of English poetry; and even in competition with that work, it may sustain itself by its different merits." It is certainly much more exact to the original, not only in meaning, but in that polish and refinement, which is so often violated by the coarseness of Dryden. It is also by no means deficient in strength and vigour; but it cannot boast of those happinesses of expression, that glow and elevation, which in the best passages of Dryden give the stamp of original genius. Pitt's translation, however, has taken a firm hold on the public, and has been repeatedly reprinted in a complete edition of Virgil in English verse, of which the Eclogues and Georgics were contributed by Dr. Warton, with various critical dissertations by himself and others. Johnson's English Poets.

Pitt, William, earl of Chatham, one of the most illustrious statesmen that ever lived, was second son of Robert Pitt, and Harriet Villiers, sister to the earl of Grandison. He was born, by his own account, entered on the books of Oxford, in St. James' parish, on the 15th of November 1708. He received the early part of his education at Eton, as a scholar on the foundation, and at the age of eighteen he was entered of Trinity college, Oxford, as a gentleman-commoner. Of his academical reputation little is known, but a copy of Latin verses on the death of George I., published in the university tribute on that occasion, may be found in the Anecdotes of his Life, &c. in three vols. 8vo. to which we shall have frequent recourse in the present article. Before he left Eton, he was occasionally afflicted with an hereditary gout, which increased during his residence at Oxford, and which at length obliged him to quit the university without taking a degree. He afterwards made the tour of part of France and part of Italy, but his disorder was too deeply rooted in his constitution to be removed by foreign travel. He, however, constantly employed the leisure, which this painful and tedious malady afforded, in the cultivation and improvement of his mind.

He first came into parliament in the month of February 1735, for the borough of Old Sarum, and being a younger brother of a large family, his fortune was inconsiderable, and his friends obtained for him a cornet's commission in the Blues. The first time Mr. Pitt spoke in the house of commons, was to second the motion of his friend Mr. (afterwards lord) Lyttelton, for a congratulatory address to his majesty, on the marriage of Frederic, prince of Wales. His exertions on this occasion obtained for him the marked attention of the prince, who was then at the head

head of the oppofition party. With this party Mr. Pitt uniformly voted, by which he incurred the difpleafure of fir Robert Walpole, who revenged himfelf by taking away his commiffion : which fact was celebrated by the following lines of his friend Lyttelton, ironically complimenting the minifter for fnatching the fervile ftandard from his hand, and raifing him to patriotic eminence.

" Long had thy virtues marked thee out for fame
Far, far fuperior to a Cornet's name;
This *gen'rous Walpole* faw, and griev'd to find
So mean a poft difgrace that noble mind:
The fervile ftandard from the free-born hand
He took, and bad thee lead the patriot band."

Mr. Pitt very foon attained the firft place, for eloquence, in the ranks of oppofition, and the minifter foon repented his rafhnefs in making him his enemy. This illuftrious young man was diftinguifhed for a fine figure, an expreffive countenance, and a melodious voice. A keen eye, a graceful manner, and pleafing addrefs, gave luftre and effect to a copious elocution, not, at firft, highly correct, but animated with the fire of genius, and frequently marked with paffages of fingular force and energy that impreffed themfelves upon the memory, and were almoft irrefiftible in their effect. "The records of the Britifh fenate," it is faid, "fcarcely prefent another name fo diftinguifhed by that eloquence which bears away with it the paffions and convictions of the hearer, and ftrikes an antagonift with awe. To thefe powers he added true elevation of mind, honour, integrity, and pure conftitutional principles." Without attempting to trace all the fteps of this ftatefman's progrefs from an oppofitionift to a member of adminiftration; we may briefly obferve, that he continually rofe in the efteem of the nation, as an able and vigilant oppofer of all meafures that appeared to him to be unconftitutional. Seven of his fpeeches preferved in Chandler's Debates, and which were delivered during the remainder of fir Robert Walpole's adminiftration, exhibit the ardour of his mind, and the comprehenfivenefs of his views as a young but truly enlightened ftatefman; but his moft important fpeech in this period of his life, was in fupport of a motion for inquiry into fir Robert Walpole's (then earl of Orford) conduct. The motion was at firft loft, but when introduced a fecond time, limiting the retrofpect to the laft ten years, it was carried; but by a minifterial manœuvre the inquiry was defeated. To popular applaufe was added a more fubftantial teftimony of approbation of his conduct, by Sarah, duchefs of Marlborough, who, in a codicil to her will, dated in 1744, bequeathed him the fum of ten thoufand pounds on the grounds of his public fervices. In 1745 Mr. Pitt was mentioned to the king, George II., by the duke of Newcaftle, as a proper perfon to fill the office of fecretary at war; but fo obnoxious was his name to his majefty, probably on account of his conftant oppofition to Hanoverian politics, that he was decidedly, and at once, rejected, and a general refignation of the Pelham party followed. In the following year they were reinftated, and Mr. Pitt was appointed to the office of vice-treafurer of Ireland. He foon after fucceeded to the lucrative place of pay-mafter of the forces, which gave him an opportunity of fhewing how difinterefted he was with regard to pecuniary concerns. His predeceffors had always held very large fums of the public money in their hands, of which they made advantage by means of the funds, but Mr. Pitt never once availed himfelf of his fituation for his own private emolument. He even refufed the ufual perquifite upon a fubfidy voted to the king of Sardinia, nor would he accept of any prefent in lieu of it. In 1754 Mr. Pitt married Hefter, daughter of Richard Grenville, a lady of great merit, of a highly cultivated mind, and of general and very extenfive knowledge, with whom he paffed the remainder of his life in uninterrupted harmony.

In 1755, when the king returned from Hanover, bringing fubfidiary treaties with Heffe-Caffel, and Ruffia for its defence, he did not fcruple to join Mr. Legge in oppofing their ratification by parliament. On this account they were both difmiffed, together with Meffrs. George and Richard Grenville. It fhould be noticed, as exhibiting a prominent feature in Mr. Pitt's character, that when turned out of his fituation, the balances belonging to his office were all lodged in the bank. Thofe who encouraged the many attempts to throw a fhade upon his moral character, were the difcoverers of the fact, to their own utter mortification and confufion. Mr. Pitt was now an eager oppofitionift, and fpoke with honeft indignation againft the favourite meafures of introducing foreign troops for the defence of the kingdom, and protecting Hanover by fubfidies; the natural force of the nation, he faid, was fufficient to repel any attack of the enemy. That ftate alone is worthy of being denominated a fovereign ftate, *qui fuis ftat viribus, non alieno pendet arbitrio:* which depends on its own ftrength, and not on foreign affiftance. The difafters with which the new war began, occafioned great diffatisfaction with the conduct of public affairs, and the nation eagerly expected a change of men and meafures; and in the autumn of 1756 a new adminiftration was formed, in which Mr. Pitt took the place of fecretary of ftate. The afpect of affairs was inftantly changed; and the vigour infufed into the public councils became immediately apparent by the formation of a national militia, to which the internal defence of the country was entrufted, while the foreign mercenaries were fent away:—by the levying of a body of Highlanders to ferve in North America:—by the difpatching of fquadrons of men of war to the Eaft and Weft Indies, and by a fuccefsful expedition to Goree on the African coaft. Mr. Pitt was ftill inimical to the war in Germany, at leaft under the conduct of the duke of Cumberland; on which account he and his friends were difmiffed from office. The public difcontent at this meafure was manifefted in the moft marked and decifive manner, and his majefty invited him very foon after to take the efficient poft in the miniftry on any terms that were agreeable to him. He refumed his poft of fecretary, and arranged a miniftry according to his own views of the neceffity of the cafe, and it was that adminiftration which raifed the Britifh nation from a ftate of depreffion and difgrace to the higheft pitch of glory and fuccefs. Of this miniftry he was the foul, and he infufed his own fpirit through every department of the ftate. The principle upon which he acted was, to difregard all party diftinctions; all family interefts; and to employ men of real talents wherever he found them. Inftead of inactive and incapable commanders, whom he found in the fervice, he filled the army and navy with men raifed to notice by their abilities and exertions. By a perpetual feries of enterprizes he kept all the national powers on the alert, and affaulted the enemy in every quarter of the globe. He gave all his own time to bufinefs and none to parade, not holding a fingle levee during his fecretaryfhip. He firft accurately informed himfelf of the practicability of his plans, and then was moft peremptory in his orders; and he provided, with the moft wonderful forefight, againft every emergency. The hiftory of Mr. Pitt's adminiftration is fo interwoven with the annals of the country, and the public events that occurred in it are fo well known, that it will be fufficient if we give a mere fummary of the moft important; and previoufly to this we may fhew the extent of his minifterial influence

fluence on his second promotion to the administration in 1757, of which we are now speaking. Mr. Pitt's first proposition, says the author of the Anecdotes, was the exclusion of lord Anson from the cabinet. The duke of Newcastle pleaded earnestly to have lord Hardwicke in the cabinet: he said it was the king's request. Mr. Pitt consented, on condition that sir Robert Henley had the great seal; this stipulation was desired by Leicester-house. Lord Temple was to be privy seal: himself secretary of state. The duke of Newcastle offered lord Temple the treasury: Mr. Pitt interposed, and said it could not be, his grace must go there himself; but if, at any time hereafter, he should think proper to retire, lord Temple should succeed him. Lord Anson was proposed for the admiralty; Mr. Pitt declared that lord Anson should never have the correspondence. The duke replied that such an alteration could not be made without his majesty's consent. Here the conference broke off. Mr. Pitt soon after had an audience with the king, when he laid before him the difference that had occurred between the duke of Newcastle and himself, concerning the admiralty. The king immediately consented that the correspondence with the naval officers, usually in the board of admiralty, should be given to Mr. Pitt, and that the board should sign the dispatches without being privy to their contents. It was at this audience Mr. Pitt said, "Sire, give me your confidence, and I will deserve it;" to which the king instantly replied "Deserve my confidence, and you shall have it;" and it is understood to have been a fact that Mr. Pitt at length so won upon the king, that he was able to turn his partialities in favour of Germany to the benefit of his country.

At the period we are speaking of, the duke of Cumberland had utterly failed in the attempt to rescue Hanover from the French, and had been obliged to make a disgraceful convention: this, for the moment, seemed to be a termination of the English interference in German affairs, but the king's predilections were not to be so defeated. He refused to ratify the convention, and was intent upon some opportunity for renewing military operations in that country, and to this, upon the victory of the king of Prussia over the French, the minister acceded, though on account of it he incurred much obloquy, and his popularity underwent a severe trial. The allied army was now to be commanded by Ferdinand, duke of Brunswick, a general of the highest reputation; the king of Prussia was to be enabled by a large subsidy to co-operate with all the effect to be expected from his extraordinary talents; and thus a diversion might be given to the French force, which would render the British arms superior in all other quarters. The event proved the justice of such expectations, and the minister seemed warranted in his emphatic sentence that America was conquered in Germany. The years 1758, 9, 60, and 61, were marked by a series of successes, interrupted almost solely by the failure of some expeditions to the coast of France; but these served to keep that country in a state of alarm, and retaliate upon it the fear of invasion which had so disgracefully depressed England at the beginning of the war. At the end of that period the navy of France was nearly annihilated, and it had scarcely a colony or settlement left in any part of the world. In the mean time, however, a change in the crown had taken place, the old king had died, and his present majesty, George III., had succeeded to the throne. The confidential, but secret advisers of the new sovereign, looked to new measures; they regarded with jealousy the vast ascendancy of the minister, then emphatically styled the *great commoner*, and his warlike spirit was considered as adverse to the re-establishment of peace, which now began to be a national wish. A negociation with France was commenced, which was rendered abortive by the intermixture of the concerns of Spain with those of this country. This intermixture was resented in strong language by Mr. Pitt, who being, at that time, furnished with intelligence of the treaty of alliance between all the branches of the house of Bourbon, called the *family compact*, warmly urged in the cabinet an immediate commencement of hostilities against Spain. He was over-ruled, and he determined that he would be no longer responsible for measures which he could not guide. He resigned his post in October 1761, and was accompanied in his retreat by lord Temple. His past services were rewarded with a peerage conferred on his wife by the style and title of baroness of Chatham, and an annuity of 3000*l.* for his own life and her's. Mr. Pitt now returned to the condition of a private member of parliament with his fortune so little improved by the posts which he had held, that his principal support was his annuity. He took no leading part in the subsequent debates, but when the preliminaries of peace, in 1762, came to be discussed in parliament, he spoke in strong terms against many of the provisions of them. When the question of general warrants was moved, in 1764, Mr. Pitt spoke against their legality; and during all the contests between the prerogative of the crown and liberty of the subject, which agitated the early part of the present reign, he uniformly supported the popular cause. On account of his high character for patriotism, a considerable accession to his fortune was produced in 1765, on the death of sir William Pynsent, who bequeathed him an estate of 3000*l.* a-year. In 1766 the formation of a new ministry was committed to him, and on this occasion he took the office of privy-seal, and was himself raised to the peerage, with the title of the earl of Chatham. He was, in this instance, deserted by his early and intimate associate lord Temple, and the marquis of Rockingham; while other men of rank and talents refused to join him; disgusted, it was believed, by the tone of superiority and haughtiness which he was too much in the habit of assuming. His administration was therefore fluctuating and unsteady; his own influence gradually declined, and upon his resignation in 1768, he was so far fallen in public estimation, that he was scarcely missed by the public. The fire of his genius was not, however, extinct, and he was roused to exertions worthy of his former reputation. He took a leading part in all the great popular questions at that time discussed in and out of parliament. He began with a spirited attack in the house of lords upon the proceedings of the house of commons in the case of the Middlesex election. The doctrine of libels, as laid down by lord Mansfield, was another subject on which the earl of Chatham vigorously maintained the principles of liberty. But it was the quarrel with the American colonies, commencing 1773 or 4, that called forth the remaining powers of this venerable patriot. He opposed with all the powers of eloquence of which he was the master, though unfortunately in vain, every harsh and coercive measure which hastened the fatal catastrophe; he made motion after motion for closing the breach after it had been effected, and he foretold, with almost prophetic accuracy, the final result. Such was his anxiety on this subject, that it drove him from his bed in the midst of pain and great debility of body, and urged him to a vehemence beyond that of his best years, and at length was the immediate cause of his death. On the 7th of April 1778, the duke of Richmond having moved an address to his majesty, on the subject of the state of the nation, in which the *necessity of admitting the independence of America was insinuated*, lord Chatham deprecated in the warmest terms such a termination as the

the ruin of Britifh greatnefs. "I rejoice," faid his lordfhip, "that the grave has not clofed upon me; that I am ftill alive to lift my voice againft the difmemberment of this ancient and moft noble monarchy. Preffed down, as I am, by the hand of infirmity, I am little able to affift my country in this moft perilous conjuncture; but, my lords, while I have fenfe and memory I will never confent to deprive the royal offspring of the houfe of Brunfwick of their faireft inheritance.—Shall this kingdom, that has furvived, whole and entire, the Danifh depredations, the Scottifh inroads, and the Norman conqueft; that has ftood the threatened invafion of the Spanifh armada, now fall proftrate before the houfe of Bourbon? Surely, my lords, this nation is no longer what it was! Shall a people that feventeen years ago was the terror of the world, now ftoop fo low as to tell its ancient and inveterate enemy, take all we have, only give us peace? It is impoffible." Lord Chatham's plan, at this moment, for conciliation with America was, no doubt, inefficient; the colonifts had paffed the Rubicon, and in 1778 nothing fhort of independence would have fatisfied them; but the dying earl thought otherwife, and he propofed to make a great impreffion upon France, to prevent her fending that affiftance to the Americans, which he knew the French court had promifed; he recommended alfo a treaty of union with the Americans; and that America fhould make peace and declare war in concert with Great Britain; that fhe fhould hoift the Britifh flag, and ufe the king's name in her courts of juftice; and he imagined that when America faw the impoffibility of deriving any affiftance from France, the congrefs would accept of thefe terms. He hoped thus at once to conquer and conciliate America by making a vigorous impreffion upon France. He faw that a war with France was unavoidable, and therefore with his ufual penetration and ardour he wifhed inftantly to ftrike the firft blow; detefting that procraftination which gave the enemy power, not only of choofing the period of his conveniency, but the firft fcenes of operation. The duke of Richmond having replied to his fpeech, lord Chatham attempted to rife to anfwer his grace, but after two or three unfuccefsful efforts to ftand, he fainted, and fell back in his feat. He was caught in the arms of fome of the lords who ftood clofe to him, and was conveyed to an adjoining room, and the houfe immediately adjourned. From this ftate of exhauftion he never recovered; he was indeed conveyed to his feat at Hayes in Kent, where he languifhed till the 11th of May 1778, when he died, in the 70th year of his age, to the fincere regret of every Britifh fubject, who had a juft fenfe of human dignity and virtue. His death, rendered peculiarly impreffive by the circumftances juft referred to, excited general fympathy. Intelligence of his deceafe being fent to London, colonel Barré, the moment he heard of the fact, haftened to the houfe of commons, who were then fitting, and communicated the melancholy information. Although the event had been, in fome meafure, expected for feveral days, yet the houfe were affected with the deepeft fenfibility. Even the adherents of the court joined in the general forrow, which was apparent in every countenance. The old members indulged a fond remembrance of the energy and melody of his voice; his commanding eye, his graceful action. The new members lamented that they fhould no more hear the precepts of his experience, nor feel the powers of his eloquence. A deep grief prevailed. The public lofs was acknowledged on all fides. Every one bore teftimony to the abilities and virtues of the deceafed, and on this occafion all appearance of party was extinguifhed. His remains were honoured with a public funeral; his debts were paid by the nation, and an annuity of 4000*l.* out of the civil lift was annexed to the earldom of Chatham. The fenfe of the extraordinary merits of this great man was not confined to his own country; it pervaded the whole of Europe, and was attefted by fome of the higheft characters in it. But of all the numerous portraits which have been drawn of him, and of which many are preferved in the "Anecdotes" already referred to, that of lord Chefterfield is the moft ftriking, and probably, upon the whole, the moft accurate. "His private life," fays the noble writer, "was ftained by no vice, nor fullied by any meannefs. All his fentiments were liberal and elevated. His ruling paffion was an unbounded ambition, which, when fupported by great abilities, and crowned with great fuccefs, make, what the world calls, a great man. He was haughty, imperious, impatient of contradiction, and overbearing—qualities which too often accompany, but always clog, great ones. He had manners and addrefs; but one might difcern through them too great a confcioufnefs of his own fuperior talents. He was a moft agreeable and lively companion in focial life, and had fuch a verfatility of wit, that he would adapt it to all forts of converfation. He had a moft happy turn to poetry, but feldom indulged, and feldom avowed it. His eloquence was of every kind, and he excelled in the argumentative as well as in the declamatory way. But his invectives were terrible, and uttered with fuch energy of diction, and fuch dignity of action and countenance, that he intimidated thofe who were the moft willing, and the beft able to encounter him. Their arms fell out of their hands, and they ftruck under the afcendant which his genius gained over theirs." Demofthenes was his great model in fpeaking, and it has been faid he tranflated fome of his orations feveral times over. But though he was delighted with the manner of this orator, who united a wonderful power of expreffion to the moft forcible method of reafoning, yet he was equally mafter of the pleafing, diffufe and paffionate ftyle of the Roman orator.

Of lord Chatham's literary productions, the chief is a volume of "Letters," written to his nephew, afterwards lord Camelford, father of the lord Camelford who was fhot a few years fince in a duel.

His lordfhip had five children, *viz.* three fons and two daughters: 1. John, the prefent earl of Chatham, born in 1756. 2. William, born in 1759, who will be the fubject of the following article. 3. James Charles, born in 1761, and who is now dead. 4. Lady Hefter, born in 1755, who married the prefent earl Stanhope, and died in the year 1780: this lady left three daughters, of whom the youngeft, lady Lucy Rachel, married Thomas Taylor, efq. and who, to the great grief of all that knew her, died March 1, 1814, having exhibited through, alas! much too fhort a life, in almoft the higheft degree, every virtue that could adorn the child, the wife, the mother, and the friend. 5. Lady Harriet, born in 1758, who married the eldeft fon of lord Eliot, and died in 1786.

Pitt, William, fecond fon of the preceding, and his fucceffor in political talent and celebrity, was born May 28th, 1759. He was educated at home, under the eye of his father, who at a very early period difcovered that in his fon were talents that would repay all the attention that could be beftowed on them, and which were likely to raife him to diftinction in the country. For the claffical education of his fon he had a domeftic tutor, but he relied entirely upon his own inftructions, communicated in converfation, for opening his mind, and giving him a turn to large and accurate enquiry. For the purpofe of accuftoming him to that facility of fpeaking, which he felt had been of great importance to his own rife in the world, he frequently made him declaim on given topics. At an age when, with the generality of young people, much remains to be learnt at fchool, Mr. Pitt

Pitt was found fully qualified for the univerfity : and accordingly, as foon as he had completed his fourteenth year, he was entered at Pembroke-hall, Cambridge, and placed under the private tuition of Dr. Prettyman, the prefent bifhop of Lincoln. At college he was diftinguifhed alike for the clofenefs of his application, and for the fuccefs of his efforts, in attaining thofe branches of knowledge to which his ftudies were particularly directed. Although no proofs are recorded of extraordinary brilliancy in his academical career, yet few young men of any rank have paffed through the probation of an univerfity with a more refpectable character for morals, abilities, induftry, and regularity. He was intended by his father for the bar and the fenate, and his education was regulated fo as to embrace both thefe objects. Soon after he quitted the univerfity, he went to the continent, and paffed a fhort time at Rheims, the capital of Champagne. The death of his illuftrious father, while he was in his 19th year, could not fail to caft a cloud over his profpects, but the foundation was laid of thofe qualities which would enable him to clear the path to eminence by his own exertions. He had already entered himfelf a ftudent of Lincoln's Inn, and as foon as he was of age, in the year 1780, he was called to the bar, went the weftern circuit once, and appeared in a few caufes as a junior counfel. His fuccefs during this fhort experiment was thought to be fuch as was amply fufficient to encourage him to purfue his legal career, and to render him almoft certain of obtaining all the wealth and honours which await the able and induftrious labourers in the vineyard of the law. He was, however, deftined to purfue a very different path, to fignalize himfelf as a ftatefman rather than as a barrifter, and to take, for a long feries of years, an active part in the regulation of the deftinies of his country and the civilized world. At the general election in 1780, he was perfuaded to offer himfelf as a candidate to reprefent the univerfity of Cambridge, but, upon enquiry, he found his intereft would not be equal to carry the election ; he therefore wifely declined the conteft. Before, however, he had completed his twenty-fecond year, he was, through the influence of fir James Lowther, returned member of parliament for the borough of Appleby. This was in the month of January 1781, a period in which an oppofition, compofed of fome of the greateft characters in the nation, was in warm contention againft the miniftry, which, under the guidance of lord North, was carrying on a difaftrous war with the American colonies. By this party the power of the crown was regarded as too great for the balance of the conftitution, and its reduction by means of certain reforms was the favourite topic of the times. For this purpofe Mr. Burke, at the commencement of the feffion, brought forward his well-known bill for an economical reform in the civil lift. It was on this occafion that Mr. Pitt, on the 26th of February, 1781, made his firft fpeech in the Britifh fenate. The attention of the houfe was naturally fixed on the fon of the illuftrious Chatham, whofe memory was ftill dear to the nation, but in a few moments the regards of the whole audience were directed to the youthful orator on his own account. Unembarraffed by the novelty of the fituation in which he had been fo lately placed, he delivered himfelf with an eafe, a grace, a richnefs of expreffion, a foundnefs of judgment, a clofenefs of argument, and a claffical accuracy of language, which not only anfwered, but exceeded, all the expectations which had been formed of him. During the fame and the fubfequent feffion, he occafionally rofe to give his fentiments on the mal-adminiftration of public affairs, and to prove that he inherited his father's abhorrence of the American war, as well as his liberal ideas on other public topics. What feemed particularly to intereft his patriotic feeling, which he unqueftionably poffeffed, at this time, was a reform of parliament. The neceffity of fome improvement of this kind had ftrongly impreffed a large proportion of the nation, and meetings of numerous bodies of men had been held in different parts, who had appointed delegates to confider of the beft plans for bringing it to effect. In one of thefe conventions, holden at the Thatched-Houfe tavern, Weftminfter, Mr. Pitt himfelf fat as a delegate. It is true that when examined on his oath, in the year 1794, on the trial of Mr. Tooke, he did not feem to remember that he fat as a delegate, though he admitted he had been engaged in attempts to obtain a parliamentary reform, for which, and which only, the prifoner, at the inftance chiefly of Mr. Pitt, was then under trial for high treafon ; but Mr. Sheridan, who was engaged with Mr. Pitt on the fame bufinefs, exprefsly declared that the meeting at which they attended was a convention to which delegates were appointed from counties, towns, and different parts, to promote the object of parliamentary reform, and to act, not for themfelves individually, but for thofe who deputed them.

As a public fpeaker, we have already obferved Mr. Pitt had opened his courfe with great fplendour, and it was foon evident to all who acted with him, or who were witneffes to the exercife of his talents, that he was apparently deftined to act a high part on the political ftage. When, however, lord North's adminiftration broke up, and a new one was formed under the aufpices of the marquis of Rockingham, Mr. Pitt was not invited to take a fhare in it. He ftill purfued the great object of parliamentary reform, and in May 1782, moved for a committee, "to enquire into the ftate of the reprefentation in parliament, and to report to the houfe their obfervations thereon" The motion was loft by a majority of twenty. Mr. Pitt did not on this occafion endeavour to difcufs the queftion as to the beft fpecies of reform ; he only afked for an enquiry, in order that a report might be made to the houfe as to the beft means of carrying into execution a moderate and fubftantial reform in the reprefentation of the people. On this and two other occafions, *viz.* in May 1783, and April 1785, he fupported the neceffity of a parliamentary reform with great eloquence, and the moft powerful reafoning, after which he abandoned the caufe for ever. It has fince been ably advocated by alderman Sawbridge, Mr. Flood, Mr. Grey, fir Francis Burdett, and the Hon. Thomas Brand. (See a fketch of various propofals for a conftitutional reform in the reprefentation of the people from 1770 to 1812, fuppofed to be drawn up by Mr. Meadley, author of the lives of Dr. Paley and Algernon Sydney.) The death of the marquis of Rockingham foon put a period to the adminiftration of which that nobleman was the bond of union, and in July 1782, lord Shelburne having, with a part of the former members, placed himfelf at the head of a new arrrangement as firft lord of the treafury, affociated Mr. Pitt, who had juft completed his 23d year, as chancellor of the exchequer : he refufed, it was faid, to occupy an inferior poft. A general peace foon followed, which was made a ground of cenfure by a very powerful oppofition ; and in April 1783, the famous coalition miniftry took the places of thofe whom they had expelled. Mr. Pitt, during his continuance in office, had found little opportunity to diftinguifh himfelf, otherwife than as an able defender of the meafures of adminiftration, and a keen animadverter upon the principles and conduct of his antagonifts. He retired with a character unimpeached, and immediately, as we have feen, refumed his efforts for promoting the reform of the reprefentation.

A circumftance foon after occurred, which was the eventual caufe not only of Mr. Pitt's return to office, but of his poffeffion of a degree of authority with the king, and of popularity with the nation, which has rarely been the lot

of

of a minifter, and which he preferved, with fhort interruptions, to the end of his life. A bill for the regulation of the territorial government in India was brought into parliament, in November 1783: the leading provifion of which was to veft the whole management of the affairs of the Eaft India Company in feven commiffioners named in the act, and of courfe to be appointed by the exifting miniftry. It was moft violently oppofed by Mr. Pitt, on account of its being a violation of the chartered rights of the Company. It neverthelefs paffed the houfe of commons by a large majority, and was of courfe carried from thence to the upper houfe. In the mean time, an alarm was raifed refpecting the inordinate power which fuch a regulation would confer upon the miniftry, and which would render them almoft, or perhaps altogether, independent of the crown. It was afterwards afcertained, that, in a private audience granted to lord Temple by his majefty, this danger was reprefented in fuch a light, that directions were fent to all the noblemen dependent upon, or in confidence with, the court, to vote againft the bill; and it was accordingly rejected. The immediate refult of this was a change of miniftry; and in the new arrangement, in December 1783, Mr. Pitt united in his own perfon the offices of firft lord of the treafury and chancellor of the exchequer; and thus in his 24th year affumed the ftation of prime minifter. Though called to this high ftation by the voice of the fovereign, he had a moft formidable oppofition to encounter in the houfe of commons; and his firft India bill was rejected, on the motion for its commitment, by a majority of eight, there being for the motion 214, and againft it 222. A fpectacle was now prefented, which in this country was regarded as very extraordinary, *viz.* that of a minifter ftanding unmoved, though oppofed to the majority of the national reprefentatives; and it was obvious he had but one of two meafures to adopt, either to retire from office, or diffolve the parliament. He chofe the latter, which took place in the month of March 1784, and of courfe a general election fucceeded. On this occafion, independently of that fort of influence, which, though namelefs, is not lefs efficacious in obtaining a majority, it evidently appeared that the voice of the nation was decidedly in favour of the minifter; and he had the fingular good fortune of being fupported as well by the friends of the royal prerogative, as by thofe of parliamentary independence, and the new parliament opened with a large majority on the minifterial fide. Mr. Pitt, on this occafion, was returned member for the univerfity of Cambridge; and his firft meafure of great importance in parliament was the paffing of his India bill with fome alterations: the effence of which was the conftituting of a board of controul appointed by the king, out of the privy council, for fuperintending the civil and military government, the revenue, and concerns of the Company; while their commercial and internal affairs were left to the management of their own directors. The king was to nominate a commander-in-chief, and to poffefs a negative upon all appointments of the Company; and a new court of judicature was inftituted for the trial of offences committed in India. Another important plan, in which he occupied himfelf, was for the prevention of fmuggling; and for this purpofe, he, by what was denominated the Commutation Act, took off the principal duties from tea, and fupplied the deficiency by a large addition to the window-tax. Through the whole of his career, Mr. Pitt obtained the moft general applaufe as a minifter of finance; and the plans which he introduced for the gradual extinction of the national debt, are ftill operating with great benefit, and have enabled this country to carry on a twenty years' war of unexampled expence. Adopting the principle of fome able writers on political arithmetic, of the vaft accumulating powers of compound intereft, he introduced, in 1786, a bill, for fetting apart a million annually for the purchafe of ftock, which fum was to be augmented by the intereft of the ftock fo purchafed. Perfeverance in this plan, with occafional improvements, has already, amidft all the preffure of public burdens, extinguifhed between two and three hundred millions of debt, and produced a very confiderable revenue to be applied to the fame purpofe. For this plan the financier was indebted to the late excellent Dr. Richard Price, who, on an application from Mr. Pitt, gave him three plans, of which he felected the leaft efficient; and for this he did not think it worth his while to make the fmalleft public acknowledgment. (See FUND and PRICE.) Mr. Pitt likewife made various alterations in the mode of collecting taxes, fo as to obviate and prevent frauds and defalcations, render them more productive, and come in aid of the great fyftem. A commercial treaty with France, in 1787, founded, as it was underftood to be, on reciprocal advantages, and fupported upon the liberal principle that neighbouring ftates, inftead of being foes and rivals, might become mutual affiftants in the progrefs to profperity, exhibited, in a faint degree, the minifter's attention to the trading intereft. It was foon difcovered, that the fuperior information of the Englifh negociators threw the benefits of the treaty fo much into their own fcale, that, upon experience of its effects, it occafioned general diffatisfaction among the merchants in France.

On the queftion of the impeachment of Mr. Haftings, Mr. Pitt, who feemed ever defirous of following public opinion, voted with the majority in favour of that meafure, though moft of his colleagues in office inclined to the other fide. A fimilar attention to the prevailing fentiments, perhaps, induced him to act as the champion of the eftablifhed church, in feveral applications from the diffenters for the repeal of the Teft and Corporation Acts (fee TEST); a meafure to which it was fuppofed that a fon of the illuftrious earl of Chatham would have naturally been inclined. Mr. Pitt entered eagerly into continental politics, and the aggrandifement of Ruffia, under the emprefs Catharine, was confidered by him as an object for the interference of the Englifh court. He formed leagues to counterbalance her power in the north; and in order to prevent her from retaining poffeffion of the fortrefs of Otchakof, he had nearly involved the two countries in a war. The unpopularity of this meafure was foon manifeft; his refolution was fhaken, and he abandoned the object altogether. He next difplayed a readinefs to recur to arms, in a difpute with Spain refpecting the fur-trade at Nootka found, which was violently oppofed in and out of parliament, and which was at length adjufted by a convention. His interference to preferve the power of the ftadtholder in Holland, and defeat the machinations of the French in that country, was a very popular meafure.

In the autumn of 1788, the people of England were thrown into a ftate of alarm, by a calamity which threatened to deprive them of their fovereign. In the beginning of October, his health appeared to be fenfibly impaired; and though he was fufficiently recovered to hold a levee on the 24th of that month, before its conclufion the diforder affumed a marked character, and moft ferious afpect. Early in the enfuing month, it became generally known that it had fettled in the brain, and had rendered his majefty incapable of exercifing the royal functions. Parliament having been prorogued to the 20th of November, it became neceffary that it fhould meet that day, as the fovereign, by whom only it could be further prorogued, was not in a fituation to aſſert his prerogative. In the mean time, the leaders of the different parties, who were materially intereſted in the event, aſſembled in the capital; and an expreſs was diſpatched to Mr. Fox, then abſent on the continent, to accelerate his return. This occurrence gave occaſion to a diſplay of the firmneſs and deciſion of Mr. Pitt's character. In this article we cannot enter into many particulars; but we may obſerve, that the firſt material queſtion brought up by this event was, in whom the office of regent was veſted? The prince of Wales being connected with the party in oppoſition, it was contended by them that the regency of courſe devolved upon him; while, on the other hand, Mr. Pitt ſupported the doctrine, that it lay in the two remaining branches of the legiſlature to fill up the office, as they ſhould judge proper; admitting, at the ſame time, that no other perſon than the prince could be thought of for the poſt. By adopting this principle, he carried with him the concurrence as well of thoſe who were attached to the popular part of the conſtitution, as of the king's friends, whoſe great object was to ſecure his return to power, on the ceſſation of his malady; and he was enabled to paſs a bill, greatly reſtricting the power of the regent, which his majeſty's timely recovery in the beginning of the year 1789 rendered abortive. Mr. Pitt was now left to purſue his plans of internal economy, without thoſe interruptions to which he had lately been ſubjected. He had received, during the diſcuſſions on the regency, very deciſive tokens of eſteem from many of the moſt reſpectable public bodies in the kingdom; and he had the ſatisfaction of knowing, that the firm and ſteady conduct which he obſerved, on a queſtion peculiarly calculated to try the firmneſs, ſteadineſs, and conſiſtency of a public character, had obtained for him, in a very marked manner, the confidence of their majeſties, and greatly increaſed his popularity throughout the nation.

The next great event in which he was to take a leading part was the French revolution, an event the moſt momentous in its conſequences that modern hiſtory records. (See Revolution, *French.*) The influence of this vaſt convulſion could not be viewed by the politician, and the miniſter of a great empire, but in a double light, as exerted upon France itſelf, and upon the neighbouring ſtates. Its principles and progreſs were, without doubt, watched with a jealous and anxious eye by Mr. Pitt, as well as by all others engaged in the ſervice of exiſting governments. That the tyrannies of Europe, the deſpotiſm exerciſed in the greater and the ſmaller ſtates, ſhould tremble at the effects likely to be produced by the French revolution, was not a matter of ſurpriſe; but the conſtitution of our own country, if not actually founded, yet built upon the principles of national liberty, had at that moment nothing to dread: and it is not ſaying too much to affirm, that if the miniſter had poſſeſſed a mind capable of taking advantage of the circumſtances as they roſe, and kept aloof from war, he might have rendered the continental ſtorms indefinitely uſeful, in promoting the proſperity of theſe iſlands. Had he led thoſe ſyſtems of reform, which, but a few years before, he had been eager to propoſe, and ſtrenuous to vindicate, he would have quieted the voice of diſcontent, and might have carried the country with him: inſtead of which, he now pertinaciouſly clung by thoſe very abuſes and corruptions, which he had formerly ſo ſucceſsfully expoſed, which gave room for invective, and at length excited thoſe clamours, which ſubſequently required a "vigour beyond the law to ſuppreſs." There is ſcarcely any doubt that Mr. Pitt was, at firſt, againſt engaging in the war againſt France; but finding the majority of the cabinet determined on the project, he gave up his principles rather than retire from the helm of government. If, however, he were tardy in entering upon hoſtilities, he made up in zeal for any moments that were loſt in diſcuſſing the principles of action. The war of England, as well as that carrying on by the allied deſpots on the continent, was againſt *French principles;* and in the conteſt, the government of this country was ſoon aided by all the great powers and authorities of the nation; by the magiſtracy, the law, the church, the army, the maſs of property hereditary and commercial. In oppoſition to this, the democratical party, if not very numerous, were actuated by an enthuſiaſtic zeal bordering on madneſs. The views of the Whigs, headed by a Grey and an Erſkine, extended only to ſuch temperate reforms as had been propoſed by the miniſter himſelf; but there were others, who were perpetually appealing to their country as to the neceſſity of thoſe more radical changes, which had been vindicated by the duke of Richmond, now an adherent to Mr. Pitt and the court, *viz.* annual parliaments, and univerſal repreſentation. Some few, but certainly very few in the whole realm, unleſs actuated by the hope of plunder, went much farther, and anticipated a revolution in this country ſimilar to that in France.

Under ſuch circumſtances, a vigilant eye and a ſteady hand were obviouſly neceſſary to ſteer the veſſel of ſtate amidſt thoſe dangers. By his own zealous adherents, Mr. Pitt obtained for the time the epithet of "the pilot who weathered the ſtorm;" but the manner in which he exerciſed the almoſt unlimited power entruſted to him, will not juſtify the application of this epithet. He had few of the qualities of a good pilot: he was more eager to engage in the battle, and to hurl the thunder of war, than to direct the motion of the veſſel. To ſound alarm as loudly as poſſible through the nation; to encourage the diſſemination of high principles of government, and involve in common obloquy all meaſures of oppoſition, and all projects of reform; to augment, according to the apparent or pretended urgency of circumſtances, the reſtrictions upon political liberty; and make ſacrifices of the ſpirit of the conſtitution to what was denominated by the government party, the public ſafety; appears to have been the ſyſtem of his domeſtic policy. For ſome time he probably had no participation in the plans for interfering in the internal concerns of France, which was the occaſion of the firſt hoſtilities: for Mr. Pitt, in the year 1792, when laying before parliament a very flattering ſtatement of the national revenue, did not heſitate to prognoſticate a long continuance of peace and proſperity. Before, however, the year was cloſed, the militia was ſuddenly called out, parliament ſummoned at the ſhorteſt poſſible notice, and war was eventually declared by this country, by withdrawing our ambaſſador from the court of France. The depoſition and execution of the unfortunate Lewis XVI., added to the circumſtances juſt referred to, rendered the war in which Mr. Pitt engaged extremely popular throughout the nation. At that time, it was imagined the conteſt would be very ſhort; that the democratic party of France would be deſtroyed; and either that the Bourbons would, in a few months, be reſtored, or that the empire itſelf would be divided among the neighbouring nations. The ill ſucceſs which attended this confederacy could not certainly be charged upon the want of vigour in the Britiſh miniſter, who entered into it apparently with his whole heart, and laviſhed all the reſources of the country upon its ſupport. In a few months, the direful effects of war were felt over the whole of Europe. The calamities that attached themſelves to our own commerce and manufactures, were great beyond example; but they were not peculiar to Britain. Bankruptcies ſpread over the whole continent of Europe, through

through France, Holland, Germany, Poland, Ruffia, Italy, and Spain; and almoft every where, in the year 1793, private as well as public credit was impaired, if not, for the feafon, totally deftroyed. In one refpect England differed, at this crifis of general diftrefs, from moft of the other European nations: her public credit was found, and, by affording a prompt and liberal affiftance to her manufacturers and merchants, the difficulties were in a fhort time overcome. It was in the midft of thefe calamities, brought on by the prevalence and extenfion of the war fyftem throughout Europe, that an able writer, and moft excellent man, now, alas! no more, thus apoftrophifed the minifter: "If I were bold enough to appreciate your political life, Mr. Pitt, I fhould be inclined to allow the outfet of it extraordinary merit. The fentiment of approbation that attended you was indeed almoft univerfal: you were the hope of the good, the pride of the wife, the idol of your country. If your official career had terminated with the difcuffions on the regency, it may be queftioned whether modern Europe could have produced a politician or an orator more ftrenuous, more exalted, more authoritative; one whofe ambition was apparently more free from felfifhnefs; who afforded to his opponents lefs room for cenfure, or gave to his friends more frequent occafions of generous triumph, and honeft applaufe. The errors that you have fallen into are natural for men long poffeffed of power uncontrolled; and in imputing them to you, I accufe you only of the weakneffes of human nature. It is natural, I believe, for fuccefsful ambition to feek new objects on which it may exert itfelf. Hence, after you had fubdued oppofition in England, you iffued forth, like another Hercules, in queft of new adventures, and traverfed the continent of Europe to feek monfters, whom you might fubdue. You could not, however, but be fenfible that the reputation of a minifter of trade and finance, which you had juftly obtained, was incompatible with that of a great war minifter, in the prefent ftate of the nation. You took, therefore, the middle line: you made preparations for fighting on every occafion, but you took care not to ftrike. England might perhaps bear the expence of arming, but could not actually go to war; and this fecret, which your three fucceffive armaments difcovered to all Europe, led Mirabeau on his death-bed to give you the name of *miniftre preparatif*.

"In men long in poffeffion of power, a fecret fympathy, unknown perhaps to themfelves, is gradually ftrengthening in favour of others in the fame fituation; and a fecret prejudice, amounting perhaps at laft to enmity, againft oppofition to power in every perfon. Hence the danger you faw to England, in the triumph of the patriots of Holland over the prince of Orange; and the fafety we acquired from the fubjugation of the Dutch by the Pruffian arms. Hence alfo the perfect compofure with which you expected the conqueft of France, by the defpots of Germany; and the fudden alarm with which you were feized, on the repulfion of that invafion, and the over-running of Flanders by the republican arms. By the freedom of Brabant, the conftitution of England might be endangered; but it became more fecure in your eye, it fhould feem, by the extenfion of defpotifm over every corner of Europe, and the fuccefs of foreign bayonets in rooting out liberty, as well as licentioufnefs in France." Such was the character of Mr. Pitt, drawn in 1793, by the mafterly hand of the late Dr. Currie, under the feigned name of Jafper Wilfon. Its likenefs, after more than twenty years, will not be difputed; and on that account we have transferred it into our columns.

We do not pretend to enter into the details of the war with France, and fhall content ourfelves with noticing a few of its confequences. Great Britain, on the whole, was triumphant on her own element; but the conteft on the continent went entirely in favour of France, who, at length, united in a confederacy againft England fome of the powers who had been her allies in the commencement. She was now obliged to attend to her defence at home, and at the fame time was preffed by an accumulation of difficulties, which native ftrength alone could have enabled her to furmount. In 1797, the bank of England was unable to anfwer the demands made upon it, and an act of parliament was paffed to allow the governors of that eftablifhment to fufpend their payments in cafh, and to fubftitute for gold and filver, notes of every defcription, even to thofe for two pounds and one pound. Another fhock to the credit of the country was a daring mutiny of the fleet; and thefe difafters had fcarcely been averted, before a moft formidable rebellion in Ireland broke out, and which was not extinguifhed without the employment of a large military force, and the adoption of fuch fanguinary meafures as were difgraceful to thofe who reforted to them. The public burthens went on accumulating in a vaft ratio, and Mr. Pitt was obliged to have recourfe to a triple affeffment, and finally to an income tax, for raifing the neceffary fupplies. In 1799, he, with the aid of pecuniary offers, produced a new confederacy, in which the numerous armies of Ruffia and Auftria were employed to overthrow the preponderancy of France, but its final iffue was completely unfortunate. In the following year Mr. Pitt had brought to effect the great and arduous meafure of an union between Great Britain and Ireland, a meafure, the true policy of which has long fince been generally acknowledged. The war with France was now become fo hopelefs with regard to any object with which it might have commenced, and the nation was fo completely wearied with protracted hoftilities, that Mr. Pitt, aware that he could make no peace correfpondent to his high language, refolved to quit the important ftation he had fo long occupied. He refigned his poft in February 1801, and was fucceeded by Mr. Addington, now lord Sidmouth. The peace of Amiens foon followed, which Mr. Pitt defended in his place in parliament. He afterward, in fome important points, joined the oppofition, and the new minifter was in a fhort time forced into a fecond French war. His talents were foon found unequal to the conteft in which he had embarked, and Mr. Pitt, in 1804, refumed his poft as firft lord of the treafury, at the head of an arrangement formed of part of the minifters then in place, with the addition of fome of his own friends. He now came into office as a war minifter, and exerted all the vigour of his character to render the conteft fuccefsful. He engaged the two great military powers of Ruffia and Auftria in a new confederacy againft France. The errors committed by them in their plan of co-operations were fatal to the caufe, and the battle of Aufterlitz put an end to the hopes of a check to the then enormous aggrandizement of an empire which feemed deftined to fway the European continent. Mr. Pitt was in a ftate of health ill calculated to meet this terrible ftroke. He had, from an early period of life, given indications of inheriting his father's gouty conftitution, with his talents, and it had been thought neceffary to make the liberal ufe of wine a part of his ordinary regimen. The habit and the neceffity, of courfe, gained ground upon him, and he did not efcape the charge of convivial intemperance. This abufe of ftrong ftimulants, added to the cares and exertions of office during the ftormy period of his adminiftration, brought on a premature exhauftion of the vital powers. In December 1805, he was recommended to go to Bath, but the change afforded him no permanent relief. On the

the 11th of January he returned to his feat at Putney, in fo debilitated a ftate, as to require four days for the performance of the journey. The phyficians, even yet, faw no danger, and they faid there was no difeafe, but great weaknefs, in confequence of an attack of the gout. On the following Sunday he appeared better, and entered upon fome points of public bufinefs with his colleagues in office: the fubject was fuppofed to relate to the diffolution of the new confederacy, by the peace of Prefburgh, which greatly agitated him. On the 17th, at a confultation of his phyficians, it was agreed, that though it was not advifable he fhould attend to bufinefs for the next two months, yet there was hope he would be able to take a part in the houfe of commons in the courfe of the winter. On the 20th, however, he grew much worfe, and it was admitted his fituation was precarious; in other words, thofe who till then had encouraged hope in the patient, now faw that he was in the moft imminent danger, and that, probably, he had not many hours to live. The bifhop of Lincoln, who never left him during his illnefs, informed him of the opinion now entertained by fir Walter Farquhar, and requefted to adminifter to him the confolations of religion. Mr. Pitt afked fir Walter, who ftood near his bed, "How long do you think I have to live?" The phyfician anfwered that he could not fay, at the fame time he expreffed a faint hope of his recovery. A half fmile on the patient's countenance fhewed that he placed this language to its true account. In anfwer to the bifhop's requeft to pray with him, Mr. Pitt replied, "I fear I have, like too many other men, neglected prayer too much, to have any ground for hope that it can be efficacious on a death-bed—but," making an effort to rife as he fpoke, "I throw myfelf entirely on the mercy of God." The bifhop then read the prayers, and Mr. Pitt appeared to join in them with a calm and humble piety. He defired that the arrangement of his papers and the fettlement of his affairs might be left to his brother and the bifhop of Lincoln. Adverting to his nieces, the daughters of earl Stanhope by his elder fifter, for whom he had manifefted the fincereft affection, he faid, "I could wifh a thoufand or fifteen hundred a-year to be given them; if the public fhould think my long fervices deferving of it." He expreffed alfo much anxiety refpecting major Stanhope, that youthful hero, who fell a facrifice to his valour at Corunna, in company with his friend and patron general fir John Moore, and his brother, who was alfo at Corunna at the fame time, and who has been engaged in all the great battles in the peninfula, and more than once feverely wounded in his country's fervice. Mr. Pitt died about four o'clock in the morning of the 23d of January 1806, in the 47th year of his age. A public funeral was decreed to his honour by parliament, and 40,000*l.* to pay thofe debts which he had incurred in his country's fervice. Public monuments have been fince erected to his memory in Weftminfter-Abbey, in the Guildhall of the city of London, and by many public bodies in different parts of the kingdom. There is no doubt that he died in poffeffion of the efteem and attachment of a large portion of his countrymen, and his political confequence was proved by the entire diffolution, at his death, of the miniftry of which he was the head, and the neceffary admiffion of a party, againft whom ftrong prejudices were known to prevail. He will long live in memory as a diftinguifhed orator, an able financier, and a man of uncommon talents: whether he is alfo to be ranked among great and enlightened ftatefmen, impartial hiftory will hereafter decide. Dr. Stock, in his interefting life of Dr. Beddoes, fpeaking of the "Effays on the public Services of Mr. Pitt," fays, "But we are as yet too near the time of action to examine, with equal impartiality, the merits of writings fo hoftile to Mr. Pitt. A great portion, however, of the events anticipated in thefe effays, is already become hiftory. The career of this celebrated ftatefman is clofed. If his meafures were good, he can no longer direct; if bad, he can no longer reftrain their influence. A long period muft elapfe, perhaps it muft be left to diftant pofterity, to trace their full influence on the deftinies of Great Britain. The cenfure which the author (Dr. Beddoes), has thrown upon his plans may be unjuft, but his anticipation of their failure was prophetical. Principles were in action, the full operation of which had not been familiar to human experience. Common political calculations, and common-place ftatefmen, were every where baffled and confounded. But however deplorably his fchemes of foreign policy may have failed, whether from deficiency in political fagacity, or from incapacity or treachery of allies; his advocates will triumphantly maintain that, in point of primary importance, he fucceeded: he faved the Englifh conftitution. If this be true, no praife can exceed his deferts, and no honours that a grateful nation can pay to his memory can be exceffive. To have preferved a conftitution, which has raifed man to the true level of his nature, which has *ripened fouls*, which fecures to every individual under its protection a degree of practical liberty of writing, of fpeaking, and of action, greater than exifts in any country on the furface of the globe, muft emblazon his name to all pofterity. Should all the other pillars that fupport the temple of his fame give way, fo long as this remained unfhaken, it would, fingly, uphold the fabric. His opponents will, however, remind us of unhallowed attempts to deprive us of thefe proud diftinctions; and they will contend, that great as are the honours that fhould be paid to his memory, if the meafures of his adminiftration fhould appear to have been really the means of preferving this glorious monument of the wifdom of our anceftors; fo great muft be the indignation that fhould purfue it, if they fhould have proved to have impaired its magnificence, to have undermined its foundations, and to have expofed us to the hazard of a conteft, in which not common interefts only are involved, but on the iffue of which is ftaked every thing that is dear to the heart of a Briton, every thing that can render life itfelf valuable and defirable."

It is not eafy to underftand what is meant by the word Conftitution: if by it is intended fimply the government by King, Lords, and Commons, Mr. Pitt found fuch a government, and left it as fafe as he found it; but it would be difficult to prove that it ever was in danger: in the very worft period,—in the years 1793 and 4,—it may be doubted, if in the whole extent of Great Britain, there could have been found a thoufand perfons, who would, whatever were their motives, have wifhed for any change in this refpect; and hence no great merit can be given to Mr. Pitt as the faviour of our mixed form of government. If, however, by the Conftitution are intended thofe guards and that fecurity of the people, which are effential to their exiftence as a free nation, it would not be eafy to fhew in what refpect Mr. Pitt was the faviour of the Conftitution. The fecurities to which we have referred, and which, in the eftimation of Blackftone and all our great conftitutional lawyers, have been regarded as the fundamentals of our excellent conftitution, are *Magna Charta*, the *Habeas Corpus Act*, the *Liberty of the Prefs*, and *Trial by Jury*. If thefe exift in a country, the people have a pure and a perfect conftitution; they need no more to render them, in every juft fenfe of the

the word, a free people. *Magna Charta* declares, that no man ſhall be impriſoned contrary to law: during Mr. Pitt's adminiſtration, many perſons were thrown into dungeons, in defiance of this wholeſome proviſion of our anceſtors. The *Habeas Corpus Act* affords an additional ſecurity from falſe and unjuſt impriſonment, and points out effectual means, for a perſon thus maltreated, as well to releaſe himſelf, though committed by the king in council, as to puniſh all thoſe who ſhall thus unconſtitutionally miſuſe their power. Mr. Pitt not only ſuſpended the operation of the Habeas Corpus act more frequently than any former miniſter, and that often without a ſhow of reaſon, but at length bargained with his ſucceſſor for an act of indemnity for all his unconſtitutional acts, ſo that the perſons thus injured in their fortune, their health, and fair fame, were prevented from ſeeking pecuniary redreſs by the law of the land. (See Woodfall's Parl. Deb. 1801. vol. ii.) The liberty of the preſs had not for a century and more been under ſuch ſhackles as it was during the adminiſtration of Mr. Pitt, and by certain bills brought into parliament, and paſſed into laws by his influence and that of lord Grenville, the tongue was fettered, and the Bill of Rights made nugatory. In one of Mr. Pitt's treaſon bills, he endeavoured to contract thoſe advantages which the ſtatute of Edward III. allows to the accuſed, by granting them leſs time than ten days to enquire into the characters of thoſe who were to try, and thoſe who were to be brought as witneſſes againſt them. When, however, he found the Houſe determined to reſiſt the innovation, he triumphantly ſaid, that "Nothing was more eaſy than utterly to defeat that wiſe and humane law, by ſending to the men accuſed a *cloud* of witneſſes," to perplex and confound them. In 1794, what he had ſaid *might* be done, *was* done, and he was ſtill prime miniſter. On the memorable ſtate trials, each priſoner had more than 200 perſons nominated as jurymen to try him, and the names of 213 perſons were given him, as thoſe who might be produced as witneſſes in the cauſe. Hence the *trial by jury* was invaded in one of the moſt important caſes that ever arreſted the public attention. This, however, was but a ſequel to his general conduct; he had extended the Exciſe and Cuſtomhouſe laws beyond all former precedent; and in many of his fiſcal regulations, he utterly diſcarded the idea of the intervention of a jury between the king and the ſubject. In a hundred of his acts, the magiſtrate is alſo made paramount to all law, and it requires but the evidence of a common thief-taker to deprive a ſubject of his liberty. Caſes of this kind are not rare; ſcarcely a month or even a week occurs, but the public papers announce, that perſons are committed to priſon for three or ſix months by the order of a police magiſtrate, who is guided in his deciſion only by the oath of a man, perhaps much worſe than he who is ſubjected to the puniſhment.

We may, indeed, proceed one ſtep farther, and ſay, that notwithſtanding the early tincture which Mr. Pitt's mind may be ſuppoſed to have received in favour of freedom and thoſe principles, which we have aſſumed, on good authority, as the bulwarks of the Britiſh conſtitution, and the voluminous additions which he made to our acts of parliament, it will be difficult to find a ſingle diſintereſted law introduced by him in favour of the liberty of the ſubject, within the whole compaſs of our ſtatute books. This fact, if it be a fact, muſt not be imputed to the ſpirit of the times; in the early periods of the preſent reign, toleration and religious liberty received ſome important acceſſions; and ſince the death of Mr. Pitt, ſhe has, under the auſpices of the preſent adminiſtration, been ſtill better treated, and a wider ſcope has been given to ſpeculative enquiry. That all improvement in civil and religious liberty ſhould have ceaſed during the twenty years of Mr. Pitt's miniſtry, cannot be accounted for if he had been, in office, what he unqueſtionably was when he firſt entered upon public life, an ardent friend to the liberties of his country. We ſhould gladly give, if authorities would ſupport us, ſome traits of a different kind to juſtify the epithet of his friends applied to him as the ſaviour of the conſtitution. With this view, we have looked through the voluminous Hiſtory of Mr. Pitt's Political Life by Mr. Gifford; but in all the ſix volumes nothing cheering, nothing favourable appears. As a private character, he was, we believe, every thing that was excellent and amiable; to this, and to his character as a man of real talent, we ſhall turn, and with that eſtimate ſhall conclude our article.

Mr. Pitt poſſeſſed no particular advantages of perſon or phyſiognomy, the firſt of which was ungraceful, the ſecond repulſive rather than attractive. As a ſpeaker he was thought to be without a rival: ſuch was the happy choice of his words, the judicious arrangement of his ſubject, and the faſcinating effect of a perennial eloquence, that his wonderful powers were acknowledged even by thoſe who happened to be prepoſſeſſed againſt his arguments. When employed in a good cauſe he was irreſiſtible; and in a bad one he could dazzle the judgment, lead the imagination captive, and ſeduce the heart, even while the mind remained firm and unconvinced. Ambition and the love of power were his ruling paſſions; his mind was elevated above the meanneſs of avarice. His perſonal integrity was unimpeached, and ſo far was he from making uſe of his opportunities to acquire wealth, that he died involved in debts, which negligence, and the demands of his public ſtation, rather than extravagance, had obliged him to contract; for his taſtes were ſimple, and he does not appear to have had a fondneſs for ſplendour or parade. His private character has been drawn by a friend, and it correſponds perfectly with other accounts that we have had from thoſe much in his confidence, and who were frequently in his company at times, when the man and not the miniſter was diſplayed in all its native colours: "With a manner ſomewhat reſerved and diſtant in what might be termed his public department, no man was ever better qualified to gain, or more ſucceſsful in fixing, the attachment of his friends, than Mr. Pitt. They ſaw all the powerful energies of his character ſoftened into the moſt perfect complacency and ſweetneſs of diſpoſition in the circles of private life, the pleaſures of which no one more cheerfully enjoyed, or more agreeably promoted, when the paramount duties he conceived himſelf to owe the public, admitted of his mixing in them. That indignant ſeverity with which he met and ſubdued what he conſidered unfounded oppoſition; that keenneſs of ſarcaſm with which he expelled and withered, as it might be ſaid, the powers of moſt of his aſſailants in debate, were exchanged in the ſociety of his intimate friends for a kindneſs of heart, a gentleneſs of demeanour, and a playfulneſs of good humour, which no one ever witneſſed without intereſt, or participated without delight." See Roſe's Examination into the Increaſe of the Revenue, &c. during the Adminiſtration of the Right Hon. William Pitt. See alſo Monthly Mag. vol. xxi. Wyvill's Political Papers. Stock's Life of Dr. Beddoes. General Biog. New Ann. Regiſt. and Parliamentary Debates.

Pitt, in *Geography*, a county of America, in North Carolina, containing 9169 inhabitants.—Alſo, a townſhip of Allegany county, Pennſylvania, containing 2441 inhabitants.

Pitt,

Pitt *Island*, an iſland in the North Pacific ocean, near the W. coaſt of North America, between Norfolk ſound and Saliſbury ſound, about 50 miles long and 13 broad. N. lat. 57° 20′.—Alſo, a ſmall iſland in the Chineſe ſea. N. lat. 10° 57′. E. long. 114° 36′.

Pitt's *Archipelago*, a range of iſlands in the North Pacific ocean, extending along the weſt coaſt of North America, about 60 miles in length; ſo called by captain Vancouver in honour of the Rt. Hon. William Pitt. N. lat. 54° 10′. W. long. 52° 15′.

PITTACIUM, Πιττακιον, in *Surgery*, a name which ſome authors give to a piece of cloth ſpread with a ſalve, to be laid on a part affected.

PITTACUS, in *Biography*, a warrior and philoſopher, reckoned among the ſeven ſages of Greece, was born at Mitylene, in Leſbos, about the year 650 B.C. In a war between his countrymen and the Athenians, he challenged to combat their general Phrymon, a man of great ſtrength, who had been a victor in the Olympic games, and vanquiſhed him by means of a concealed net, which he threw over the enemy's head. As a reward for his valour he was offered a very large tract of land, which he had recovered from the enemy, but he would accept no more than he could meaſure by a ſingle caſt of the javelin, and of this even he conſecrated half to Apollo. He afterwards expelled the tyrant Melanchrus from Mitylene; and having liberated his country, was placed by his fellow citizens at its head. He now governed with as much wiſdom as he had fought with bravery. He enacted many uſeful laws, and in order that they might be the better remembered he comprehended them in 600 verſes. In one of theſe he gave a ſevere check to the propenſity of the people to drunkenneſs, by enjoining a double puniſhment for crimes committed in that ſtate. After having held the reins of government during ten years with high reputation, he reſigned his authority, and ſpent the remainder of his life in ſtudy and retirement. He died about the year 570 B.C. The maxims of Pittacus were held in ſuch high eſteem, that many of them were inſcribed upon the walls of the temple of Delphi. The following may be given as ſpecimens of them: "Power diſcovers the man;" "Whatever you do, do it well;" "Be watchful for opportunities." Enfield's Hiſt. Phil.

PITTANCE, from *pictantia*, a ſmall coin of Poictou, ſee Du Cange; a ſmall portion of food, or *entremet*, in oppoſition to *generale*, or a ſolid diſh, the mention of which pittance frequently occurs in the conſtitutions of our ancient communities, where they determine how many *generalia* and how many *pictantiæ* ſhall be ſerved up on ſuch and ſuch days. Theſe pittances, from whence our preſent word pittance is derived, uſually conſiſted of plates of legumes, cheeſe, or fruit.

PITTARO, in *Geography*, a mountain of Calabria Ultra; 14 miles N.W. of Bova.

PITTEN, a town of Auſtria; 8 miles S. of Ebenfurth.

PITTENWEEM, a royal borough and ſea-port town, is ſituated in the diſtrict of St. Andrew's, and the ſouth-eaſt coaſt of the county of Fife, Scotland. It was formerly a place of conſiderable trade, but there is now few ſhipping here. The coal and ſalt-works, however, ſtill occaſion ſome little activity here and in the adjacent villages. Pittenweem was firſt conſtituted a royal borough by king James V. in 1547; and now enjoys the privilege, in conjunction with Crail, of ſending one member to the imperial parliament. In the rebellion in the ſeventeenth century this town ſuffered greatly, upwards of thirteen ſail of veſſels belonging to the port having been deſtroyed or taken by the enemy in the courſe of two or three years. Here are ſome remains of an ancient priory for canons regular of the order of St. Auguſtine, which was dedicated to the Virgin Mary, and was a cell to the mitred abbey of St. Andrew's. This priory had large landed poſſeſſions, together with the churches of Rhind, Anſtruther Weſter, &c., which are now erected into a regality called the regality of Pittenweem, under the juriſdiction of lairds of Anſtruther as heritable bailies. About half-way between the ruins and the beach is a great cave, or weem, whence the borough derives its name. It conſiſts of two ſpacious apartments, at the junction of which is a ſtair leading to a ſubterraneous paſſage, which formerly communicated with the monaſtery, but which has long been blocked up by the earth falling in. There is alſo another ſtair ſtill remaining, which leads from the refectory to the further extremity of this paſſage.

Pittenweem, with reſpect to church government, is in the preſbytery of St. Andrew's and ſynod of Fife. It is diſtant about 33½ miles N.E. by N. from Edinburgh; and according to the parliamentary returns of 1811, contains 194 houſes and 1096 inhabitants. The late learned John Douglas, D.D., lord biſhop of Saliſbury, was a native of this town. His lordſhip is well known in the literary world as the vindicator of Milton, from the charge of plagiariſm brought againſt him by Lauder. He was one of the truſtees of the Britiſh Muſeum, and co-vice-preſident of the Society of Antiquaries in London. Carliſle's Topographical Dictionary of Wales, vol. ii. 4to. Beauties of Scotland, vol. iv.

PITTERSBERG, a town of the duchy of Carinthia; 3 miles N. of Mauten.

PITTI, a ſmall iſland in the ſtraits of Malacca, N. lat. 2°. E. long. 101° 29′.

PITTONIA, in *Botany*, ſo named by Plumier, in honour of his great countryman and contemporary, Joſeph Pitton de Tournefort. (See Tournefortia.) Linnæus, according to the rule he had laid down, preferred the latter appellation, as derived from the name by which the perſon commemorated was univerſally known, out of his own country; and the example has been followed by all following writers, even in France; at leaſt in this inſtance. In ſome caſes there has been a contrariety of opinion. (See Louichea and Fontanesia.) Such difficulties are for the future removed, by the ſimplification of French ſurnames, ſince the revolution.

PITTOSPORUM, ſo named by ſir Joſeph Banks, according to Gærtner. The word is derived from πιττοω, *to beſmear with pitch*, and σπερμα, *ſeed* or *offspring*; becauſe the ſeeds are enveloped in a pitchy fluid, exuding internally from the capſule as it ripens; a circumſtance altogether peculiar, thus happily expreſſed in the generic name.—Gærtn. v. 1. 286. t. 59. Schreb. 150. Willd. Sp. Pl. v. 1. 1145. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 27. Lamarck Dict. v. 5. 361. Illuſtr. t. 143.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Dumoſæ*, Linn. *Rhamni*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five, generally very deep, acute, equal ſegments, deciduous. *Cor.* Petals five, inſerted into the receptacle, alternate with the ſegments of the calyx, oblong, equal; their claws longer than the calyx, linear, channelled, erect, converging in the form of a tube; border ovate-oblong, ſpreading, recurved. *Stam.* Filaments five, inſerted into the receptacle, alternate with the petals, the length of the claws, linear, compreſſed; anthers incumbent, arrow-ſhaped, ſimple. *Piſt.* Germen ſuperior, roundiſh; ſtyle awl-ſhaped, the length of the ſtamens; ſtigma obtuſe. *Peric.* Capſule roundiſh, angular, pointed, of from two to five cells and as many

many valves, the partitions from the middle of each valve. *Seeds* three or four in each cell, angular, inserted into the inner edges of the partitions, enveloped in a refinous fluid produced by the infide of the valves.

Eff. Ch. Calyx five-cleft, deciduous. Petals five, converging into a tube. Capfule of feveral cells and as many valves. Seeds enveloped in a liquid refin.

1. P. *coriaceum*. Thick-leaved Pitch-feed. Ait. n. 1. Willd. n. 1. Vahl Symb. v. 2. 43. Andr. Repof. t. 151.—Leaves obovate, obtufe, coriaceous, very fmooth. Capfules of two valves.—Native of Madeira. A greenhoufe fhrub, flowering in May, faid to have been firft raifed by Meffrs. Lee and Kennedy, about the year 1783. The *ftem* is fix or eight feet high, bufhy, with round, finely downy, *branches*, leafy at their fummits. *Leaves* crowded, alternate, two or three inches long, remarkably coriaceous, of a fine green, fmooth and even, not fhining, with one rib, and numerous fcarcely vifible tranfverfe veins. *Footftalks* fhort, broad, channelled, downy when young. *Stipulas* large, broad, folitary, withinfide of the footftalks. *Flowers* feveral, in terminal bracteated umbels, with downy ftalks, white, powerfully fragrant, like Jafmine, but of fhort duration. *Calyx* divided to the very bafe, and finally falling off in feparate portions. *Petals* obovate, obtufe, recurved, fcarcely revolute. *Germen* elliptic-oblong. *Capfule* faid to have only two valves, a point we have had no means of determining.

2. P. *Tobira*. Gloffy-leaved Pitch-feed. Ait. n. 2. Sims in Curt. Mag. t. 1396. (Euonymus Tobira; Thunb. Jap. 99. Willd. Sp. Pl. v. 1. 1130. Tobira; Kæmpf. Am. Exot. 796. t. 797.)—Leaves obovate, obtufe, coriaceous, very fmooth and fhining. Capfules of three valves.—Native of Japan. Brought by an India fhip from China to Kew, in 1804, where it flowers abundantly in fummer, being a hardy greenhoufe fhrub. This is fo like the foregoing, that it is not eafy to difcern a fpecific difference between them. The *leaves* of the *Tobira* however are of a more fhining and darker green above; pale beneath. *Capfule*, on a fpecimen from Kew, triangular, and of courfe having three valves. *Flower-ftalks* and *germen* very hairy, as in the *coriaceum*, though none of the figures of either give the leaft indication of fuch a circumftance. Kæmpfer's plate fhews the *inflorefcence* to be fomewhat racemofe.

3. P. *revolutum*. Downy-leaved Pitch-feed. Ait. n. 3.—"Leaves elliptical, bluntifh; downy beneath; revolute at the margin."—Native of New South Wales. Sent by fir Jofeph Banks to Kew, in 1795. It flowers from March to Auguft, and is a greenhoufe fhrub, like the two above defcribed. We have two fpecimens from Port Jackfon, anfwering to the character we have copied, except that the *leaves* are acute, and indeed pointed, in both. The *flowers* in one grow five or fix together, in a ftalked hairy *umbel*; in the other they ftand in pairs, on very fhort *ftalks*, which at length become thick and woody, fupporting a large woody *capfule*, of three reflexed valves, whofe partitions are but flightly prominent. Thefe fpecimens appear to conftitute different fpecies, and probably will be better explained in the fequel of Mr. Brown's Prodromus.

4. P. *ferrugineum*. Rufty Pitch-feed. Ait. n. 4. (Cortex filarius; Rumph. Amboin. v. 7. 13. t. 7.—Leaves elliptical, taper-pointed, fmooth. Footftalks clothed with rufty down. Calyx equally divided to the bafe.—We received fpecimens of this, in March 1789, from Mr. Hoy at Sion-houfe. It is faid in Hort. Kew. to be a native of Guinea, and to have been introduced before 1787, by the earl of Tankerville, flowering in the ftove from February to May. We are poffeffed of fine fpecimens of this very plant, gathered by the late Mr. Chriftopher Smith in Oma, one of the Molucca ifles, near Amboyna, but without any mention of its name or properties. Cortex filarius of Rumphius appears to be the fame thing. The author never faw the *flowers*, but his reprefentation and defcription of the bivalve *fruit* exactly anfwers to the genus before us. He fpeaks of the bark as affording a fort of thread. Of this indeed we can obferve no figns, in our dried fpecimens, but every other part of his defcription agrees exactly. The *ftem* is fhrubby, rather flender, determinately branched; young *branches* round, clothed with rufty down, leafy towards the ends. *Leaves* fcattered or crowded, elliptic-lanceolate, pointed at each end, two or three inches long, entire, flightly wavy, with one rib and feveral tranfverfe veins ending in minute reticulations; fmooth on both fides, except an occafional pubefcence on the ribs; paler and more opaque beneath. *Footftalks* three-quarters of an inch long, flender, channelled, clothed with fine, fhining, rufty down. *Flowers* very numerous, fmall, white, in long-ftalked, aggregate, rufty, downy *umbels*. *Calyx* almoft fmooth, in five deep, awl-pointed, recurved fegments, not fo fpeedily deciduous as in fome other fpecies. *Petals* folded fpirally over each other in the bud; recurved when expanded. *Anthers* obtufe. *Germen* very hairy. *Style* fhort. *Stigma* capitate. We have feen nothing of the *fruit*, or even the enlarged germen.

5. P. *undulatum*. Wave-leaved Pitch-feed. Ait. n. 5. Venten. Jard. de Cels, t. 76. Andr. Repof. t. 383.—Leaves elliptical, pointed, fmooth; waved at the margin. Footftalks nearly fmooth. Calyx five-toothed, fplit on one fide to the bafe.—Native of New South Wales. Communicated to Kew garden, in 1789, by fir J. Banks. A greenhoufe fhrub, flowering from April to June. Its habit is very much like the laft, but every part is larger. The *leaves* are more wavy; their adult *footftalks* fmooth, though downy when young. *Flowers* white, fragrant, full twice as large as thofe of *P. ferrugineum*, but much fewer, in folitary, nearly fimple, feffile *umbels*, whofe ftalks are nearly fmooth. *Calyx* effentially different, being divided only one-third of its length into five acute fegments, though fplit down to the bafe at one fide, fometimes in two places; one tooth, in the latter cafe, being entirely feparate to the bottom. The whole *calyx* foon falls off. Its infide and edges are a little downy. Ventenat's account of the *inflorefcence* differs from our's, but we find fome parts of our fpecimens have, as he fays, three-flowered ftalks. He errs in giving the Canary iflands as the native country of this fpecies, confounding its hiftory with that of the *coriaceum*. What Gærtner has defcribed, under the names of *tenuifolium* and *umbellatum*, are probably diftinct from all the above, or he would have been cited in Hort. Kew. As he gives no fpecific characters, we can form no juft idea of thefe fpecies. Poffibly his *tenuifolium* may be our *undulatum*. Here again we muft recur to Mr. Brown's future communications, in the long-expected continuation of his work.

PITTQUOTTING, in *Geography*, an Indian fettlement in the ftate of Ohio, at the mouth of Huron river, which difcharges itfelf into lake Erie.

PITTSBOROUGH, or PITTSBURG, a town of America, the capital of Chatham county, North Carolina, fituated on an eminence, and containing a court-houfe, a gaol, and about 40 or 50 houfes. The adjacent country is fertile and well cultivated; and is much reforted to from the maritime parts of the ftate in the fickly months. The Hickory mountain is not far diftant, and both the air and water are here

here as pure as any in the world; 26 miles S.W. of Hillſborough.

PITTSBURG, a poſt-town of Pennſylvania, the capital of Allegany county, ſituated on a beautiful plain terminating in a point, between the Allegany and Monongahela rivers; and about a quarter of a mile above their confluence, by which they form the Ohio. This town was laid out on Penn's plan in the year 1765. It contains between 200 and 300 houſes, 4768 inhabitants, a gaol, court-houſe, Preſbyterian church, a church for German Lutherans, an academy, a brewery, and a diſtillery. It has been lately fortified, and a party of troops has been ſtationed in it. The hills on the Monongahela ſide are very high, extend down the Ohio, and abound with coals. Before the revolution one of theſe coal hills took fire and continued burning for eight years; when it was effectually extinguiſhed by part of the hill giving way and filling up the cavity. The ſituation, in the midſt of hills covered with trees, is delightful. At the diſtance of 100 miles up the Allegany is a ſmall creek, which in ſome places boils or bubbles forth, like the waters of the Hell Gate in the ſtate of New York, from which proceeds an oily ſubſtance, deemed by the people of the country an infallible cure for weakneſs in the ſtomach, rheumatic pains, ſore breaſts in women, bruiſes, &c. The oil is collected and brought to Pittſburg for ſale. The navigation of the Ohio, in a dry ſeaſon, is rather troubleſome from Pittſburg to the Miege town, about 15 miles; but from thence to the Miſſiſippi there is always water ſufficient for barges carrying from 100 to 200 tons burden; 393 miles W. by N. from Philadelphia. This town is a thoroughfare for the incredible number of travellers from the eaſtern and middle ſtates to the ſettlements on the Ohio; and is very rapidly increaſing. At or near this place ſhip-building is an object of great attention. It was formerly in the hands of the French, and then called Fort du Queſne, afterwards fort Pitt, in honour of the late lord Chatham. General Braddock, advancing at the head of Britiſh troops to take it in 1756, fell in an ambuſcade and was killed; 4 miles from Pittſburg. N. lat. 48° 31′ 44″. W. long 80° 8′.—Alſo, a townſhip of America, in Frontinac county, Upper Canada, adjoining to Kingſton, and here opening weſtward to lake Ontario.

PITTSFIELD, a pleaſant poſt-town of Maſſachuſetts, in Berkſhire; 6 miles N. of Lenox. This townſhip, and alſo thoſe N. and S. of it, are ſituated in a rich vale from one to ſeven miles wide, on the banks of Houſatonic river. It was incorporated in 1761, and contains 2665 inhabitants.—Alſo, a townſhip of Rockingham county, New Hampſhire, incorporated in 1782, and containing 1050 inhabitants.—Alſo, the north-eaſternmoſt townſhip of Rutland county, Vermont, containing 338 inhabitants.—Alſo, a town in Otſego county, New York; 12 miles W.S.W. of Cooperſtown.

PITTSFORD, a town of America, in Rutland county, Vermont, containing 1936 inhabitants.

PITTSGROVE, a town of America, in the county of Salem, New Jerſey, containing 1991 inhabitants.

PITTSTON, a town of America, in the county of Kennebec, and diſtrict of Maine, containing 1018 inhabitants.

PITTSTOWN, a poſt-town of Hunterdon county, New Jerſey; 58 miles N.N.E. of Philadelphia.—Alſo, a townſhip of Renſſelaer county, New York.—Alſo, a poſt-town in Luzerne county, Pennſylvania.

PITTSYLVANIA, a county of Virginia, containing, in 1810, 17,172 inhabitants. At the court houſe is a poſt-office, 300 miles from Waſhington.

PITTY, the moſt weſterly of the mouths of the river Indus, which ſeparates it from the Darraway, 50 miles below Tatta, and runs into the ſea, N. lat. 24° 42′. E. long. 66° 22′.

PITUINA, in the *Materia Medica*, a name for the reſin of the pitch-tree.

PITUITA, in *Medicine*, is the ſame with the Latin writers, as the *phlegma* of the Greeks. See PHLEGM.

PITUITARY GLAND, in *Anatomy*, called alſo hypophyſis; a ſmall body lodged in the ſella Turcica of the ſphenoid bone, and connected to the baſis of the brain. See BRAIN.

PITUITARY *Membrane*, is the lining of the naſal cavities. See NOSE.

PITUITARY *Sinuſes*, are the hollows in the body of the ſphenoid bone communicating with the noſe. See CRANIUM.

PITUM HOTUN, in *Geography*, a town of Chineſe Tartary; 438 miles E. of Peking. N. lat. 40° 18′. E. long. 125° 21′.

PITUMBA, in *Botany*, a word that occurs in Schreber's index, and, by his reference, ſeems ſynonimous with his *Wolfia*, under which however it is not mentioned. Thoſe who are fortunate enough to meet with it in any book, may perhaps by that means diſcover what *Wolfia* is, of which we profeſs ourſelves ignorant.

PITY, in *Ethics*. See COMPASSION.

PITYCIA, in *Ancient Geography*, an iſland of the Adriatic ſea, on the coaſt of Liburnia.

PITYDES, a name uſed by ſome authors for the kernels incloſed in the cones of the fir or pitch-tree; they are recommended by the old phyſicians in diſorders of the breaſt.

PITYLISMA, a name of one of the exerciſes deſcribed by the ancient phyſicians, as of great ſervice in chronic caſes. It conſiſted in a perſon's walking on tip-toe, and ſtretching his hands as high above his head as he could, keeping the whole body alſo as much upon the ſtretch as might be. In this condition the patient was to walk as far as he was well able, all the while moving about both hands as much as he could, in all directions.

PITYNERA METROPOLIS, in *Ancient Geography*, the ancient Golconda on the right bank of the river Nerva, a town of India, in the interior of the peninſula on this ſide of the Ganges, according to Ptolemy, who makes it the capital of the people called "Meſoles." On the map of M. d'Anville, it is placed on a river, which runs towards the S.W. into the Meſolus.

PITYONESUS, an iſland on the coaſt of the Peloponneſus, ſix miles from the continent, over-againſt Epidaurus.

PITYRIASIS, πιτυρίασις, in *Medicine*, from πιτυρον, *furfur*, *bran*, a ſlight ſcaly or ſcurfy affection of the ſkin, appearing in irregular patches, ſometimes with, and ſometimes without, ſlight redneſs or inflammation, upon which ſmall thin ſcales repeatedly form and ſeparate; but they never collect into cruſts, and are not accompanied by excoriations.

Such is the character of this cutaneous affection, as pointed out by Dr. Willan, in contradiſtinction from the other ſcaly diſeaſes of the ſkin, lepra, and pſoriaſis. The Greek writers have not preciſely agreed in their acceptation of the word pityriaſis. Galen, Aëtius, and Oribaſius, ſpeak of it as affecting the head only: Alexander of Tralles, however, and Paul of Ægina, the ableſt of the later Greeks, have deſcribed the diſorder generally, as conſiſting of "ſlight ſcaly and branny exfoliations, without ulceration." All the tranſlators of the Greek writings into Latin

Latin have rendered the word pityriasis by *porrigo;* not observing that the best Roman authority, Celsus, included under the term "porrigo" not only the *pityriasis*, but the *ceria* and *achores* of the Greeks. As, however, the porrigo is a contagious disease, Dr. Willan justly deemed it expedient to separate the non-contagious pityriasis from it, and included only the ceria (or *favi*) and achores under the former term. See PORRIGO.

Of this slight and non-contagious eruption, three or four varieties have been noticed. The *first* is the pityriasis *capitis*, or *dandriff* (as it is called by the nurses) of infants. This affection shews itself in a slight whitish scurf along the top of the forehead and temples, but in larger, flat, separate, semi-transparent scales on the occiput. A similar affection sometimes occurs on the scalp of aged persons. With a view to cure this form of the eruption, it is only necessary to enforce a regular ablution of the scalp with soap and water, or with an alkaline or weak spirituous lotion; for which purpose the hair must be removed, if it be not thin.

The *second* species, or pityriasis *rubra*, occurs most frequently in adult or even advanced life, and is the result of a slight inflammation of the portions of the skin affected. The cuticle is at first only red and rough, but soon becomes mealy or scurfy, and exfoliates, leaving a similar red cuticle underneath, which undergoes the like process; and as the exfoliation is repeated, the scaliness is augmented. This complaint is attended with a dry and unperspiring state of the skin, and with a troublesome itching, and a feeling of stiffness. When the redness and scales disappear, the patches are left of a yellowish or sallow hue; but the whole process is apt to be repeated at short intervals, and the disease to be thus greatly prolonged. It is sometimes accompanied with a general languor and restlessness. This form of pityriasis is removed by the decoctions of sarsaparilla, elm-bark, &c. combined with antimonials, and with the use of the warm salt-water baths.

The *third* form, or pityriasis *versicolor*, is not uncommon in adult persons of both sexes, and is most remarkable for the chequered and variegated discoloration of the skin which accompanies it. It occurs mostly about the breast and pit of the stomach, and sometimes on the arms and shoulders, in brown patches of different shades, variously branching and coalescing, and interspersed with portions of the natural hue. There is generally a slight scurfy roughness on the discoloured parts; but this is in some cases scarcely perceptible, and there is no elevation or distinct border to the patches. It is to be remarked, that these patches do not appear, like ephelides and freckles, on the face and hands, which are exposed to the sun, but chiefly on covered parts, as was long ago remarked by Sennertus, who has given an accurate description of this eruption under the appellation of "*maculæ hepaticæ*," or *liver-spots*, probably from their colour. See his Pract. Med. lib. v. part iii. sect. i. cap. 7.

The pityriasis versicolor is in itself of little moment; for it is not accompanied by internal or constitutional disorder, and very rarely by any troublesome sensations, if we except a slight itching when the patient becomes warm in bed, after strong exercise, or drinking warm liquors. It is sometimes, however, supposed to be the consequence of the venereal poison, from its brown and almost coppery hue. But independently of its indisposition to terminate in ulceration, however long it may remain, its distribution and situation, and the absence of all other syphilitic symptoms, will be sufficient to enable an observer of moderate experience to distinguish it. Those who have resided in warm climates seem to be most liable to this disorder. Dr. Willan has stated, that internal medicines have not appeared to have much influence on this eruption: but Dr. Bateman is of opinion, that the oxygenated muriatic acid is possessed of some efficacy, and that the use of pitch, in the form of pills, would probably be serviceable. Externally, however, active stimulant applications have often decidedly removed the disorder; such as lotions containing alcohol, muriatic acid, or caustic potass, properly diluted with distilled water. Sea-bathing has also been found beneficial.

There is also a *fourth* variety, the pityriasis *nigra*, which seems to have been noticed only in children born in India, and brought to this country. It is said to have commenced in a partially papulated form, terminating in a black discoloration of the skin, with slight branny exfoliations; and to have sometimes affected half a limb, as the arm or leg, or sometimes the fingers and toes. See Willan on Cutan. Diseases, part ii.; and Bateman's Pract. Synops. of Cutan. Diseases, p. 44.

PITYRODIA, in *Botany*, πιτυρώδης, branny. Brown Prodr. Nov. Holl. v. 1. 513.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Verbenaceæ*, Juss. in Ann. du Mus. v. 7. 63. Brown.

Eff. Ch. Calyx bell-shaped, in five equal segments. Corolla funnel-shaped; its upper lip cloven half-way down; lower in three deep equal segments. Stigma cloven. Drupa dry at the summit, of four cells, perforated at the base. Seeds solitary in each cell.

1. P. *salvifolia*.—Found by Mr. Brown in the tropical part of New Holland. A *shrub*, with scaly or bran-like pubescence; whence the name was chosen. *Leaves* opposite, simple, lanceolate, nearly entire, rugose, with a strong smell, and nearly the taste of mint. *Flower-stalks* axillary, opposite, many-flowered, densely clustered. *Flowers* white. This genus is very nearly akin to *Callicarpa*. *Brown*.

PITYUS, in *Ancient Geography*, a town situated upon the Euxine sea, at the distance of 44 miles W. from Dioscurias, or Sebastopolis, which was considered as the utmost boundary of the Roman empire, according to Arrian. This city was provided with a convenient port, and fortified with a strong wall. The Goths, in their first naval expedition, met at this place with resistance more obstinate than they had reason to expect from the feeble garrison of a distant fortress; they were repulsed; and their disappointment seemed to diminish the terror of the Gothic name. As long as Successianus, an officer of superior rank and merit, defended that frontier, all their efforts were ineffectual; but as soon as he was removed by Valerian to a more honourable but less important station, they resumed the attack of Pityus; and, by the destruction of that city, obliterated the memory of their former disgrace.—Also, a river of Asia, in the Colchide.

PITYUSA, an island of the Ægean sea, in the Hermonic gulf, S.E. of the peninsula of the Argolide, and S. of the promontory Bucephalium.

PITYUSÆ INSULÆ, islands of the Pityuses, or of Pines, so called on account of the number of these trees which grow upon these islands. Ebusus or Ivica, &c. belonged to this group.

PITYUSE ISLES, in *Geography*, are islands of the Mediterranean, contradistinguished from the *Balearic*, and so called, according to Ptolemy, Strabo, and Pomponius Mela, from the Greek word πίτυς, *a pine*, whence πιτυοῦσσα, abounding in pines. These are Ivica, which is the largest, (see IVICA,) Fromentera, S. of Ivica, separated from the coast by a channel one league and a quarter in breadth, three leagues in extent from E. to W., and from two leagues to a quarter of a league in breadth, containing about 200 inhabitants, and supplying

plying wood, ftone, and corn, from which laft article it is faid to derive its prefent name; the three Conejeras to the weft of the former, which, though of confiderable extent, are deftitute of habitations, and furnifh food for the flocks of the neighbouring ifles; three fmall iflands, called the gates of Ivica; the ifle of Groffa; the ifles of Santa Eulalia y de Arabi, lying towards the E.; the ifles of Margueritas, &c. The inhabitants of thefe iflands, the climate of which is mild and healthy, pay little attention to commerce; but as the land, which is mountainous and well wooded, is adapted to all forts of hufbandry, the occupiers cultivate olives, vines, and corn; and raife from thefe productions a greater quantity than they confume; but they are forbidden to export corn, oil, and fruits, and therefore, notwithftanding the richnefs and productivenefs of their foil, they almoft all live in a fort of indigence; falt and wool are the only commodities which are exported in foreign bottoms. Their habits are much the fame with thofe of the inhabitants of the Balearic iflands, one of the chief of which is indolence; their language is alfo much the fame. They keep a number of holidays, which they devote to the purpofes of religion, or fuperftition; and they have affemblies and fome amufements. They are reckoned courageous, and difplay proofs of valour in their contefts with the pirates on the coaft of Barbary. The people are in general ignorant, and have hitherto little availed themfelves of any opportunities or means of improvement.

PITZEN, a town of Pruffia, in the province of Bartenland; 9 miles S.S.W. of Raftenburg.

PITZIUNTA, or DANDAR, a town of Circaffia. N. lat. 43° 45′. E. long. 59° 10′.

PIVA, *Ital.*, a bagpipe. See CORNAMUSA.

PIUHEGA, in *Geography*, a town of Italy, in the department of the Mincio; 4 miles N. of Mantua.

PIVOT, or PEVOT, a foot or fhoe of iron, or other metal, ufually conical, or terminating in a point; whereby a body intended to turn round bears on another fixed at reft, and performs its circumvolution.

The pivot ufually bears or turns round in a fole or piece of iron or brafs, hollowed to receive it.

Large gates, &c. ufually turn on pivots. The ancients tell us, they had theatres in Rome, that held eighty thoufand people, which have yet turned on a fingle pivot.

PIVOT (*Fr.*), in *Military Language*, is that officer, ferjeant, corporal, or foldier, upon whom the different wheelings are made in military *evolutions*; which fee. Of thefe pivots, two forts are diftinguifhed according to the pofition of the troops that are governed by them; *viz. ftanding* and *moveable* pivots. When a battalion, *e. g.* ftands in open column of companies, the "right in front," the laft man upon the left of the front rank of each company, is called the *inner*, or *ftanding* pivot; and the firft man upon the right ditto is called the *outer*, or *wheeling flank*. The accurate pofition of the different pivots is an object of great importance with regard to military movements, and officers, in particular, ought to recollect, that when they are pofted upon the flanks, they become abfolutely neceffary to the prefervation of that perpendicular and parallel order of a march, without which direction, the beft concerted manœuvres muft be ultimately rendered ufelefs. At the inftant when an officer has wheeled his divifion, he muft refume his perpendicular pofition, look fteadfaftly on his leading pivot, maintain his relative diftance, and keep his perfon perfectly fquare. He ought likewife to be particularly correct in ftepping off when the wheel is completed. The *moveable* pivot is one which, during the wheel of its divifion, advances in a circular direction, inftead of turning on the fpot where it originally ftood. Thus, when divifions, &c. are fucceffively wheeled, without being firft halted, the pivot upon which they wheel is faid to be *moveable.* In the drill, fingle ranks are frequently wheeled on a moveable pivot. In which cafe, both flanks are moveable, and defcribe concentric circles round a point, which is a few paces diftant from that which otherwife would be the ftanding flank; and all eyes are turned towards the directing pivot man, whether he is on the outward flank, or on the flank to which the wheel is made.

PIVOT-*Flanks*, the flanks upon which a line is formed from column. When the right of the battalion is in front, the pivot-flanks are on the left of its feveral companies, platoons, &c. and *vice verfa*, when the left is in front.

PIVOT-*Flank Officer*, the officer who is on the firft flank. In all wheelings during the march in column, the officer on that flank upon which the wheel is made, muft confider himfelf as the pivot.

PIVOTS, *Platoon*, the men upon whom a battalion marches in column of platoons, is wheeled up into line, or backward into column, when the line has been formed according to a given point.

PIURA, in *Geography*, a river of Peru, which runs into the Pacific ocean, S. lat. 5° 33′.

PIURA, a town of Peru, and capital of a jurifdiction of the fame name, in the bifhopric of Truxillo. This was the firft Spanifh fettlement in that country, and was founded in the year 1531, by don Francifco Pizarro, who built the firft church in it. It ftood firft in the valley of Targafale, and was called "St. Miguel di Piura;" but it was removed, on account of the infalubrity of the air, to its prefent fituation, on a fandy plain. The houfes are conftructed either of bricks baked in the fun, or of a kind of cane called quincas, and they have generally only one ftory. The corregidor, and an officer for collecting the royal revenue, refide here and at Payta fix months alternately. The town contains about 1500 inhabitants, none of whom are perfons of diftinction. Although the climate is hot and dry, it is not upon the whole unhealthy. As the country is level, water is eafily conveyed to different parts by canals. But in fummer, when water is fcarce, they are under a neceffity of procuring it by digging wells in the bed of the river. This town has an hofpital, under the care of the Bethlehemites, which is remarkable for the cures afforded to a great number of perfons labouring under the venereal difeafe; 25 miles S.S.E. of Payta. S. lat. 5° 15′. W. long. 80° 40′.

PIUS I., pope, in *Biography*, a native of Aquileia, who flourifhed in the fecond century, was probably the fucceffor of Hyginus, and in that cafe commenced his pontificate about the year 143. According to Eufebius, he died in the year 157. Other hiftorians, as Cave, Pearfon, and Dodwell, imagine that he prefided over the fee of Rome between the years 127 and 142, while Bellarmine and Baronius date his elevation to that high dignity in the year 158. In the Roman martyrology he is faid to have fuffered death, for the fake of his religion, under the reign of Antoninus Pius, but there feems no good authority for this fact, and the title of martyr is not given to him by Irenæus. Two "Letters" to "Juftus of Vienne," which were formerly attributed to Pius, may be found in the fecond volume of the "Orthodoxographia," and likewife in the "Bibl. Patrum," but they have long fince been given up as fpurious, and allowed to be the production of a much later age. Moreri. Bower.

PIUS II., pope, whofe original name was Æneas-Sylvius-Piccolomini, was defcended from one of the moft illuftrious families of Sienna, in Tufcany, which had been expelled

pelled from that city, together with the reſt of the nobility, by the popular faction, and ſettled at the ſmall town of Corſignano. At this place he was born in 1405, and afterwards initiated in the rudiments of grammar learning, but by the loſſes ſuſtained by his father in thoſe times of trouble and turbulence, he was unable to procure for Æneas the benefits of a college courſe of education, and the youth was under the neceſſity of aſſiſting in the labour by which the family was ſupported. His talents and deſire of literary improvement led ſome of his friends and relations, about the year 1428, to ſend him to the univerſity of Sienna, where he was maintained at their expence. He quickly afforded ſtrong proofs of an extraordinary genius. He applied himſelf with ardour to the ſtudy of the belles lettres, making himſelf acquainted with the writings of the poets and orators, and during his academical courſe, he publiſhed ſeveral Latin and Italian poems, which were received with applauſe by the learned. After this he directed his attention to the civil law. In the year 1431, his learning and accompliſhments recommended him to the notice of cardinal Copronica, whom he accompanied to the council of Baſil in the capacity of ſecretary. Here he gained the confidence of the fathers, by the zeal with which he eſpouſed their cauſe againſt pope Eugenius, and the many learned and elegant ſpeeches which he made, to prove the ſuperiority of general councils over the biſhops of Rome. He was immediately raiſed to the important offices of ſecretary to the council, clerk of the ceremonies, abbreviator of the letters, and one of the collators to benefices. He was alſo employed by the council on miſſions of importance to Trent, Conſtance, Frankfort, Swabia, Straſburg, Savoy, and the Griſons, and as a compenſation for his very uſeful ſervices, he was preſented to the provoſtſhip of the collegiate church of St. Lawrence at Milan. He was ſuperior to the threats and anathemas of Eugenius, and continued firm in his adherence to the fathers, while a multitude of others deſerted their cauſe through fear. His example prevented many from defection, who were wavering as to the ſide they ſhould eſpouſe. On account of his reſolution and zeal, when the council paſſed ſentence of depoſition againſt the pope, in the year 1439, and elected Amadeus, duke of Savoy, in his ſtead, Æneas was made ſecretary to the newly elected pontiff. Shortly after this, he was ſent to promote the intereſt of Felix, at the court of the new emperor, Frederic III., where he was honoured by that ſovereign with the title of poet-laureat, and even admitted into the number of his perſonal friends. In 1442 the emperor prevailed upon him to reſign his other offices, and to enter wholly into his ſervice, on which occaſion he was made prothonotary, or ſecretary to the empire, and diſtinguiſhed with the dignity of ſenator. From this time he appears to have had higher objects of ambition than he had before conceived, and he omitted no means of ſtrengthening his own intereſt, by adopting all the ſentiments of his imperial maſter. When, therefore, the emperor embraced a neutrality between the council of Baſil and Eugenius, Æneas, notwithſtanding what he had before done, followed his maſter's example. Afterwards, when the emperor ſeemed inclined to the cauſe of Eugenius, in oppoſition to that of the council and Felix, Æneas conformed himſelf to his ſentiments, and repreſented his perſon at the diet of Ratiſbon, where the means of putting an end to the ſchiſm in the church were taken into conſideration. At length, in 1446 and 1447, he was ſent by Frederic to Rome, to negociate the ſubmiſſion of Germany to Eugenius; of which opportunity he availed himſelf to ſhew contrition for his paſt conduct, and ſolicit with all humility the forgiveneſs and favour of his holineſs. Eugenius met his wiſhes, but did not live long enough to beſtow upon him any ſubſtantial mark of his regard. By his ſucceſſor, Nicholas V., Æneas was preferred to the vacant ſee of Trieſte, in Iſtria; and upon his return to Germany he was made one of the council to whom was entruſted the management of the moſt important concerns of the empire. Four years afterwards he was tranſlated to the vacant ſee of Sienna. In the year 1451, he accompanied Frederic to Rome, when he went thither to be crowned by the pope, and on his return, the biſhop was inveſted with the legantine power over Bohemia, and the whole Auſtrian dominions. After this, in the year 1456, he was promoted by Callixtus III. to the dignity of cardinal, and upon the death of that pontiff he attained the great object of his ambition, being raiſed, by the unanimous ſuffrages of the conclave, to the popedom, and at his coronation, he aſſumed the name of Pius II. Much was expected from him on account of his great learning, and the zeal which he had formerly ſhewn in ſetting forth the corruptions that had been introduced into the church. He, however, ſoon convinced his friends, and the friends to a better order of things, what they had to hope for now he was elevated to the higheſt ſtation in the world. His ambition was gratified, and what formerly had been deemed corrupt principles and practice, he found means to juſtify, or at leaſt overlook. One of the firſt meaſures of his government was an attempt to unite the Chriſtian princes againſt the Turks: for this purpoſe he appointed a council to meet at Mantua in 1459, at which he invited all thoſe princes to attend, either in perſon or by their ambaſſadors, for the purpoſe of deliberating on the moſt effectual methods of delivering Chriſtendom from the bondage with which it was threatened by thoſe formidable enemies. At this council Pius himſelf preſided, and the attendance of princes or their repreſentatives was very numerous; but their various and oppoſing intereſts rendered all the endeavours of the pope to unite them quite ineffectual, and the council broke up without concurring in any reſolution to oppoſe the progreſs of the common enemy. He next declared the kingdom of Naples devolved as a fief of the church to the apoſtolic ſee, and confirmed the bull of king Ferdinand's legitimation, upon his reſtoring to the church ſome places that had been captured by his father. He alſo granted Ferdinand the inveſtiture, and ſent a cardinal to perform the ceremony of his coronation. The king, on his part, engaged to aſſiſt the pope againſt his enemies with the whole ſtrength of his kingdom. To ſecure the throne of Naples to Ferdinand, Pius ordered all the clergy and barons, under pain of excommunication, to acknowledge him, and no other, for their lawful ſovereign, and ſent a body of troops to his aſſiſtance when John of Anjou invaded the kingdom. In 1460 he gave a moſt decided proof of his bad faith, by publiſhing a bull, condemning the doctrine, which he had formerly defended, of the ſuperiority of a general council to the pope, and forbidding all appeals to ſuch a council under the ſevereſt penalties. He alſo attempted to obtain from Charles VII. king of France, the revocation of the PRAGMATIC *Sanction*, (ſee that article,) which he pronounced to be an edict highly derogatory to the honour and dignity of the holy ſee. This edict had been drawn up by Charles, or at leaſt by the prelates of his kingdom, and it was thought neceſſary, in order to deliver the French clergy from the vexations which they ſuffered from the encroachments of the popes, ever ſince the latter had fixed their reſidence at Avignon. It had been drawn up in concert with the fathers of the council at Baſil, and the articles of which it conſiſted were taken from the decrees of that council. In anſwer to Pius's requeſt, the French king

 replied,

replied, that the edict confifted of the very decrees of the council of Bafil, which Pius himfelf had approved, had penned, and probably had fuggefted, when fecretary to that affembly, and which it had received with one confent, and obferved for the fpace of twenty-five years by the whole French nation. Upon the death of Charles, the pontiff renewed his application to his fucceffor Lewis XI., who confented to abolifh the edict by a folemn declaration, for which he and his fucceffors were rewarded by the title of "Moft Chriftian," a title which defcended uninterruptedly to Lewis XVI., and was only abolifhed with the deftruction of the monarchy. Though the king thus degraded himfelf by becoming a tool to the pope's ambition, his council better confulted the dignity of their fovereign, and their own reputation, by refifting, to a man, the pope's demand; and the full execution of Lewis's declaration was prevented by the noble ftand made by the univerfity of Paris, and the parliament, in favour of the "Pragmatic Sanction."

During the years 1462-3, Pius again, but unfuccefsfully employed all his talents and eloquence in endeavouring to unite the Chriftian princes againft the Turks, who had at that time made themfelves mafters of almoft all Greece. Finding his efforts of no avail, he equipped a fleet at Ancona, avowing his determination, notwithftanding his age and bodily infirmities, to face the inconveniences and dangers of war, imagining, that with fuch an example, the Chriftian princes would be afhamed of remaining quiet and inactive at home. While, however, he was thus bufily employed, he fell fick, and was advifed by his phyficians to pay a vifit to Sienna, for the benefit of his native air. Before he left Rome, he publifhed a folemn retractation of all that he had written in favour of the council of Bafil, and declared, without fhame or hefitation, that, as Æneas Sylvius he was a damnable heretic, but as Pius II. he was an orthodox pontiff. After a very fhort ftay at Sienna he returned to Rome, but being informed of the inroads of the Turks, and that they had actually laid fiege to Ragufa in Dalmatia, he fet out without delay for Ancona, though at that time he was in fo infirm a ftate of health, as to be obliged to travel in a litter. The journey, however, proved too much for him, and he died in the fummer of 1464, at the age of fifty-nine, having filled the pontifical throne fix years within a few days. According to Platina, he was endowed with every virtue that became his exalted ftate; but the conduct of the pope certainly militated againft the excellent qualities which he had difplayed, previoufly to his advancement to that high dignity. No man ever laboured harder, and perhaps few more fuccefsfully than Æneas Sylvius, to reftrain the power of the pope within the boundaries admitted by the canons, and no pope ever ftrove more than Pius II. to extend that power beyond all the bounds of reafon and law. To effect his purpofes, he fpared neither kings, dukes, nor people, when he affumed that they invaded the rights of the church, or entrenched upon the emoluments of the clergy. When young he indulged his paffion for the fex without reftraint, and in his more mature years, he feems to have thought tranfgreffions againft the rules of chaftity to be very venial fins, if they could even be denominated fins. As a fcholar, he was an elegant writer in Latin, and left behind him various works, moft of which he compofed before his elevation to the popedom. Of thefe an abridged lift is given in the General Biography, but a complete catalogue of them may be found in Cave and Dupin. The following feem to be the moft generally important: "Comment. de Geftis Concilii Bafilienfis;" "De Ortu, Regione, ac Geftis Bohemorum ad Ann. 1458;" "Cofmographiæ, feu Hiftoriarum de Mundo univerfo;" "Epiftolarum Liber," containing four hundred and thirty-two letters, many of which are interefting and curious. The whole works of this pope were publifhed in a collective form at Bafil in 1551, and again at Helmftadt in 1700. A hiftory of his life was publifhed at Rome in 1584, which was generally believed to have been drawn up by himfelf. Moreri. Mofheim.

Pius III., pope, whofe original name was Francis Todefchini, was a native of Sienna, and born in the year 1429. He was nephew on the maternal fide to Pius II., and was permitted to take the name of Piccolomini, and to bear the arms of that family. When he was but twenty-two years of age, Pius raifed him to the dignity of cardinal, and nominated him to the bifhopric of Sienna. He was employed in feveral legations by popes Paul II., Innocent VIII., and Alexander VI., to whom he gave the moft entire fatisfaction, by the prudence and integrity with which he difcharged the feveral commiffions and high trufts repofed in him. Upon the death of Alexander VI. in 1503, the city of Rome was thrown into the utmoft confufion by the ftruggles for power between Valentine Borgia, the fon of Alexander, and the Orfini, and others whom he had deprived of their eftates. Scarcely a day paffed in which there were not battles fought in the ftreets by the partifans of thefe rivals. The cardinals, therefore, found it quite neceffary to raife a confiderable body of troops for their own defence, while they fhould be fhut up in conclave. They alfo applied to the ambaffadors then refiding in Rome, by whofe means the heads of the oppofite factions were prevailed upon to withdraw from the city, till the election of the new pope fhould be declared. The choice foon fell upon Piccolomini, who, out of grateful refpect to the memory of his uncle, affumed the name of Pius III. As foon as the intelligence of his election had reached the hoftile factions, they returned to Rome, and renewed the war within the walls, throwing the city into the utmoft confufion. Valentine was foon obliged to fubmit to the enemy, and he was then left to the mercy of the pope, who permitted him to retire unmolefted wherever he pleafed. Pius, by this event, had the happinefs to fee peace reftored to the city, but he did not live long to enjoy it, as he died on the 26th day after his election, being in the 75th year of his age. It was generally believed, that he was taken off by poifon. He was regarded as a perfon of unblemifhed moral conduct, and in every refpect worthy of the high dignity to which he had been raifed. Bower. Moreri.

Pius IV., pope, whofe original name was John Angelo di Medici, was born at Milan in the year 1499. He wifhed to be thought a branch of the famous houfe of Medici, to which he had no real pretenfions, being, in fact, of low origin, and whofe real name was Medicino inftead of Medici. He enjoyed the advantages of a liberal education; and having applied himfelf chiefly to the ftudy of the civil law, he was in early life admitted to the degree of doctor. After this he practifed with high reputation as a civilian, and by his abilities, united with the intereft of a brother, he obtained the office of prothonotary under Clement VII. In this fituation he recommended himfelf to the favour and patronage of cardinal Farnefe, who, after his elevation to the papal dignity under the title of Paul III., employed him in various legations. By the fame pope he was appointed commiffary to the army of the church; nominated archbifhop of Ragufa; and created cardinal prieft of Santa Prifca in the year 1549. Upon the death of pope Paul IV., in 1559, the conclave was agitated for more than four months by the intrigues of different cardinals of noble families, whofe power was fo equally balanced, that neither of them

them could obtain the requifite fuperiority over his rivals; till at length, wearied out with their fruitlefs ftruggles, they gave their united votes in favour of the cardinal of Santa Prifca; who, at his confecration, took the name of Pius IV. He began his pontificate with granting a general pardon to all who had been concerned in the outrages committed fince the death of his predeceffor, and he then took meafures for bringing to juftice the perfons whofe oppreffive enormities had provoked them to their irregular conduct. The Caraffas were accordingly arrefted, tried, and convicted of crimes, for which they were condemned to forfeit their lives and their eftates. The cardinal was, in purfuance of the fentence, ftrangled; and his two brothers, the duke of Pagliano and marquis of Montebello, were beheaded, with feveral of their accomplices. One of the early meafures of this pope's adminiftration was to terminate the differences between the papal and imperial courts, occafioned by the late pope's refufal to approve Ferdinand's fucceffion to the imperial crown, refigned to him by his brother Charles V., without applying in the firft inftance for the confent of his holinefs. He next adopted certain meafures, with a view, if poffible, of putting a ftop to the progrefs of the reformation. The power and influence of the Proteftants were now every day becoming more and more confiderable. England and Scotland had difclaimed allegiance to the fee of Rome, and had new-modelled their religion. In the Netherlands, the reformers had greatly multiplied; and in France, there was reafon to apprehend that they foon might become too powerful for the Catholics. The new opinions had penetrated even to Italy. From Naples they were extirpated by Philip II., who iffued orders to his viceroy to put all heretics to death without mercy. But the duke of Savoy was inclined to attempt to enlighten and convert them; and, with this view, he defired the pope's permiffion to hold a conference of the principal ecclefiaftics in his dominions, on the fubject of religion. France determined to have recourfe to the fame expedient. The pope promifed that he would fummon a general council without delay, which he did, to meet at Trent. The bull was drawn up in fuch equivocal expreffions, as might be interpreted to fignify either a new council, or a continuation of the former one at the fame place. The emperor, the French king, Philip, and the other Catholic princes, received the bull, and gave orders to the ecclefiaftics in their dominions to repair to Trent, at the time appointed. An invitation to attend was alfo fent to the feveral Proteftant powers; but they all refolved to give no encouragement to a council, which was called by one whofe authority they could not acknowledge, and in which only thofe were to have decifive votes, who had fworn allegiance to the pope and the fee of Rome. The council opened in January, 1562. Attempts were foon made to abridge the authority of the pope, which created in his holinefs perpetual anxiety, and he was on the point of fuddenly diffolving the affembly; but he found it more expedient to flatter and cajole, than to have recourfe to violent meafures. In 1563 it was brought to an end, but not until decrees were paffed, defigned as an acknowledgment of the fubordination of the council to the holy fee. When information of the diffolution of the council was brought to Pius, he received it with great joy, and ordained a folemn thankfgiving on the occafion; and in a very fhort time, he publifhed a bull of confirmation, requiring all the prelates and princes to receive and enforce the decrees of the council of Trent, prohibiting perfons from writing any explication or commentary of them, and commanding the Catholics every where to have recourfe in all doubtful cafes to the apoftolic fee. By the republic of Venice, the feveral Italian princes, moft of the Catholics in Germany, and the king of Spain, the authority of the council was acknowledged, and the decrees received; in fome countries, without any limitation whatever; but in Spain, and all through the Spanifh dominions, with the claufe, "Saving the rights of the crown, and the privileges of the fubjects." Pius had the mortification to find that they met with a different treatment in France. The court refufed to receive and publifh the decrees, as derogatory to the liberties of the Gallican church, and the rights of the crown. In the year 1564 the pope, at the prefling inftance of the emperor Maximilian II., granted the ufe of the cup to the laity of Auftria and Bohemia; but he could not be perfuaded to confent to the marriage of the priefts, though earneftly intreated by the emperor, and the other Catholic princes of Germany, who declared that they could no longer bear with the impure celibacy of the clergy. This pope died in 1565, in the 67th year of his age, and after a pontificate of nearly fix years. That event is faid to have been accelerated by his apprehenfions for the lofs of Malta, which was then befieged by the Turks. The news of the fact was received with great joy by the Roman people, who hated the pontiff, on account of the feverity and oppreffion of his government. This hatred, united with religious enthufiafm, had given rife to a confpiracy againft him not long before his death; but it was difcovered, and the parties concerned in it were executed with much torture. Pius is praifed for the vaft fums which he laid out on public works, for the convenience and ornament of Rome. According to Onuphrius, he was poffeffed, or at leaft feemed to be poffeffed, while cardinal, of every virtue that could render him worthy of the high ftation to which he had been raifed; but no fooner had he attained the fummit of his ambition, than he abandoned himfelf, without reftraint, to all the oppofite vices; ftopping at no means of accumulating wealth, that he might enrich and aggrandife his nephews and other relations.

Pius V., pope, whofe original name was Michael Ghiflieri, was defcended from an obfcure family, and born at Bofchi, a fmall town near Alexandria, in the north of Italy, in the year 1504. When he was fourteen years of age, he embraced the monaftic life in a Dominican convent, where he was foon diftinguifhed by the ftrictnefs of his conformity to the rules of the order, and acquired a high character for piety and virtue. He was ordained prieft at Genoa, and became a very celebrated preacher, being mafter of a moft powerful and perfuafive eloquence. Afterwards he was elected prior of the convent of Vigevani, and nominated inquifitor by cardinal Caraffa, commiffary-general of the holy office, who had conceived a ftrong attachment to him. In a fhort time after, that cardinal was elevated to the papal throne, under the name of Paul IV. He made Ghiflieri bifhop of Sutri; and when, in the year 1557, our prelate was preparing to refign his dignity, and to return to the monaftery, he was prevented by the interpofition of his holinefs, who promoted him to the purple, by the title of cardinal *de fancta Sabina*, though he was moft commonly known by the name of cardinal Alexandrini, from his native country. He was, at the fame time, appointed to the poft of commiffary-general to the inquifition. This office he executed with fo much feverity in the Milanefe and Lombardy, that he was obliged to quit thofe countries; and his zeal was afterwards checked by the government, when he attempted to difcharge the functions of inquifitor at Venice. Pius IV. tranflated him from Sutri to the fee of Mundovi; and upon the death of that pontiff in 1566, by the unanimous fuffrages of the conclave, he was elected his fucceffor, when he affumed the name of Pius V. The people expreffed no joy at his coronation: they dreaded a fevere government under a man, in whofe rigid and auftere manners his fucceffive promotions from the condition of a fimple monk had made no change. Senfible of the coldnefs of the reception he met with, he obferved to thofe about him, "I hope that, fome time hence, the Romans will be as forry for my death, as they are now grieved at my advancement." To render his name worthy of the grateful remembrance of virtuous and good men, he difplayed great zeal and diligence in promoting a reformation in the manners and morals of all ranks of the people. He repreffed the exceffive pride and oftentation of the cardinals, as well as the luxury in drefs and mode of living of the other orders of the clergy. He gave directions for banifhing all the proftitutes from Rome, and he prohibited the bull-fights in the circus, as well as all other diverfions which had a tendency to promote irregularity and diffipation among the lower claffes. He gave directions for ftrictly enjoining on the clergy refidence, and commanded that no perfons fhould be admitted to ecclefiaftical benefices, who would not refide; and when he was told, that a ftrict adherence to fuch a decree would caufe the court of Rome to be deferted, he replied, that it was better that the court fhould be deferted, than that the fervice of the altar fhould be neglected. He ordered his own relations to retire from Rome, providing them all with fmall penfions for their fubfiftence, excepting two nephews, who were attached to ftudy; one of whom, Michael Bonello, who poffeffed fhining talents and an excellent difpofition, he was perfuaded by his friends to raife to the dignity of cardinal. While Pius V. was engaged in introducing a partial reformation among the ecclefiaftics and community of Rome, he difplayed a furious zeal againft the Proteftants, by perfecuting them with the fame favage feverity, which rendered him odious in his former character of inquifitor. Peter Carnefecchi, a perfon of diftinction at Florence, was, by his exprefs order, condemned to the flames, after having been convicted of correfponding with fome of the reformed religion in Germany, and with fome of his countrymen in Italy, who were fufpected of herefy. Aonius Palearius (fee his article), one of the ornaments of his age as an elegant and liberal fcholar, underwent the fame fate, for faying that in fome things the Lutherans were excufable, particularly for calling the inquifition "the dagger drawn againft literature in general." Not fatisfied with his endeavours to extirpate the reformed opinions out of Italy, he, in 1568, encouraged Charles IX., king of France, to make war upon his Proteftant fubjects; fending a confiderable body of troops to join the royal army, and permitting fome of the eftates of the church in France to be alienated, in order to fupply funds for carrying on hoftilities. Pius V. was not outdone by any of his predeceffors in zeal for maintaining the high claims of the papal fee. In 1568 he publifhed his famous bull, entitled "In Cœna Domini," which it was ufual to publifh at Rome on Maundy Thurfday every year, till it was fuppreffed by pope Clement XIV. By this bull, anathemas were pronounced againft fuch perfons as fhould appeal to general councils from the decrees of the popes, and againft thofe princes who fhould impofe reftraints on ecclefiaftical jurifdictions, or exact contributions from the clergy. This bull, evidently calculated to deprive princes of their fovereignty, and to render them and their fubjects entirely dependent on the will of the Roman pontiffs, was never received in any kingdom out of Italy. Some French bifhops did, a few years afterwards, attempt to introduce it into their diocefes; but their offence againft the liberties of the Gallican church was moft feverely punifhed. In 1569 Pius conferred the title of grand duke of Tufcany upon Cofmo de Medici, duke of Florence, who went to Rome, where he received the crown at the hand of his holinefs; and during the fame year, the pope iffued a bull of excommunication againft Elizabeth, queen of England, abfolving her fubjects from their allegiance. This paper was fixed up in the night on the bifhop of London's palace, and in other parts of the metropolis; but it was very harmlefs, for none but a few bigotted Catholics noticed it with the fmalleft regard: they indeed endeavoured to excite fome commotions, but their efforts were fruitlefs, and for the feeble attempt they paid the forfeit of their lives.

In the year 1571, the zeal of this pontiff was directed againft Selim the Turkifh fultan, who, in violation of a folemn treaty, had invaded the ifland of Cyprus. The Venetians, to whom the ifland belonged, folicited his holinefs to employ his influence in procuring affiftance for them from the Chriftian princes. With their requeft Pius readily complied. He was, however, fuccefsful in his application only with Philip II., who, without hefitation, entered into a league with his holinefs and the republic, by which he bound himfelf to pay one-half of the expence of a powerful armament which it was judged neceffary to employ, while the Venetians engaged to defray three-fourths of the other half, and the pope the remainder. The preparations of the combined powers were carried on with fo much celerity and difpatch, that about the middle of September a fleet was ready to fail from Meffina, confifting of more than 250 fhips of war, and other veffels, carrying nearly 50,000 men. The command of this mighty armament was given to don John of Auftria, whom the pope, indulging the moft fanguine hopes with regard to the iffue of the war, exhorted to embrace the firft opportunity of engaging with the enemy, affuring him that he would obtain a complete victory. He fent him, at the fame time, a confecrated ftandard, and a number of ecclefiaftics to officiate in facred things on board the fhips; and, moreover, he ordered a faft and jubilee to be proclaimed, with an abfolution from their fins to all who fhould acquit themfelves with honour againft the infidels. A victory was foon afterwards obtained by this fleet over the Turks near the gulf of Lepanto, the intelligence of which fpread univerfal joy throughout all Chriftian Europe. When the important news was brought to the pope, he cried out, in the words of facred writ, "There was a man fent from God, whofe name was John," in reference to the prince under whofe command the victory was obtained. (See JOHN *of Auftria*.) Pius furvived this event only a few months, and was carried off by an attack of the ftone in 1572, when he was about the age of fixty-eight, after a pontificate of little more than fix years. Notwithftanding his defects, compared with many of his predeceffors, his name appears with honourable diftinction among the lift of popes. He was a lover and patron of learned men, and fcarcely preferred any perfons to confiderable dignities who were not ftrongly recommended by their abilities, and the endowments of their minds. In his private conduct he was irreproachable and exemplary. He was beatified by Clement VIII., and canonized in 1712 by Clement XI. A volume of his letters was publifhed at Antwerp in 1640, under the title of "Apoftolicarum Pii Quinti Pontificis maximi Epiftolarum, lib. v." Moreri. Bower.

PIUS VI. pope, originally known by the name of John Anthony Brafchi, was defcended from a noble, but reduced family, and born at Cefena, a fmall town belonging to the ecclefiaftical ftate, in the year 1717. Being deftined for the church, and poffeffing a promifing capacity, he received the beft education that could be procured. His

fplendid

ſplendid talents recommended him to the patronage of cardinal Ruffo, who appointed him to the poſt of uditore; a charge which, in the eſtabliſhment of the Roman church, compriſed the offices of vicar, counſellor, and aſſiſtant. In this ſituation he conducted himſelf with ſo much good ſenſe, probity, and zeal, that he ſecured the affection of the cardinal, and acquired the reputation of being one of the beſt informed perſons in Rome. As a mark of his eſteem for Braſchi, this generous prelate, when on his death-bed, left him the continuation of his appointment for life, and ſuch was Braſchi's veneration for his patron, that, out of reſpect for his memory, he retained the ſituation of uditore, even after he became pope. He continued to make rapid advances in the church, and under the pontificate of Clement XIV., more generally known by his family name of Ganganelli, Braſchi was raiſed to the purple; and in this progreſſive advancement, he conſtantly diſplayed a love of juſtice, the ſtricteſt morality, cloſe application to buſineſs, and the moſt unaſſuming manners. After the death of Clement XIV., cardinal Braſchi was raiſed to the pontifical throne, and he was proclaimed pope under the title of Pius VI. He began his government with correcting various abuſes which had taken place in the internal adminiſtration of affairs, as well as in the police of Rome, and with endeavours to reſtore the dilapidated finances to order and regularity. With this view he liberally patronized ſeveral uſeful reforms, and beneficial eſtabliſhments in the ſtate. Soon after his acceſſion he had a difference with the court of Naples, which led him to diſplay great firmneſs in ſupport of his dignity. The king of the two Sicilies had appointed M. Filangeri, formerly viceroy of Sicily, to the archbiſhopric of Naples; and as the laws of that metropolis required that the archbiſhop ſhould be a cardinal, application was made to Pius VI. to beſtow upon him that dignity. The pope returned for anſwer, that although the laws enacted that a cardinal ſhould be the archbiſhop, it did not follow that the archbiſhop ſhould become a cardinal; and that his majeſty, who could not be inſenſible of the difference, might have promoted to the archbiſhopric ſome one or other of the Neapolitan cardinals reſiding at Rome, inſtead of thus indirectly aſſuming authority to confer one of the greateſt dignities of a foreign hierarchy on one of his ſubjects. The pope was reſolute, and Filangeri actually died of a broken heart, in conſequence of the refuſal. Pius VI. derived real and very great honour from the works of magnificence and utility, on which he expended the revenues of his ſee. He augmented and completed the noble Clementine Muſeum in the Vatican, founded by his predeceſſor, as a receptacle for the monuments, vaſes, ſtatues, medals, and other remains of antiquity, which were procured by excavations in the eſtates of the church. The engravings and deſcriptions of the treaſures in this collection were afterwards publiſhed in ſix volumes folio. He projected and finiſhed the erection of the preſent majeſtic veſtry of St. Peter's. He built a church and eſtabliſhed a library in the abbey of Subiaco; he founded a number of hoſpitals for the relief of the ſick and indigent; and he ſhewed a great regard for the intereſts of commerce by repairing the port of Ancona, and erecting the beautiful light-houſe, which is at once an ornament to the city, and of the higheſt utility in the navigation of the Adriatic ſea.

But the greateſt economical undertaking of this pontiff's adminiſtration, was the draining of the Pontine marſhes; and if he did not completely ſucceed, yet he is not entitled to leſs praiſe for the grandeur and utility of the attempt. The marſhes extended upwards of forty miles in every direction, occupying the whole valley from the Apennines to the ſea. To fit this vaſt ſpace for the purpoſes of agriculture, and by ſo doing to purify the air from peſtilential vapours ariſing from it, had been an object that employed the thoughts and the labours of the cenſor Appius Claudius, who carried through it the famous Appian way. Several of the Roman emperors, and ſeveral of the popes had directed, at different times, their attention to the ſame deſign, and though all their attempts had been unſucceſsful, Pius VI. reſolved to undertake the arduous work. He employed the beſt engineers in Rome, and went regularly every year to inſpect, in perſon, the progreſs which they had made. He cauſed immenſe canals to be dug, for the purpoſe of receiving the water from the marſhes, and by this means rendered conſiderable tracts of land fit for huſbandry. On the ſide of theſe canals he conſtructed a large and beautiful road, about forty miles in length, ornamented with four rows of poplar trees, and interſperſed with houſes of accommodation; and at its termination he built a large and ſplendid palace. Pius likewiſe diſplayed his magnificence in the reception which he gave to ſeveral royal perſonages from various parts of Europe, who came to viſit Rome during his pontificate, among whom were Joſeph II. emperor of Germany; Paul, then grand duke, afterwards emperor of Ruſſia; Guſtavus Adolphus, king of Sweden; and his royal highneſs of England, prince Auguſtus Frederic, the preſent duke of Suſſex, illuſtrious as well for his attachment to the principles of civil and religious liberty, as for his high birth.

Pius VI. ſpent the firſt ſix years of his pontificate in the moſt perfect tranquillity, excepting the difference, which has been referred to, with the court of Naples, occupied in regulating the internal government of his ſtate, and in carrying on the undertakings already noticed. Soon after the death of the empreſs queen, Maria Thereſa, towards the end of the year 1780, he began to feel mortifications and afflictions in abundance. As ſoon as Joſeph II. came into poſſeſſion of his hereditary territories, he began to carry into execution the ſchemes which he had long formed for promoting a reform in eccleſiaſtical affairs, and emancipating his ſubjects from papal juriſdiction. With this view he iſſued edicts and ordinances, by which the ſecular clergy were ſubjected to lay-magiſtrates: all donations to religious houſes, by thoſe who ſhould enter them, were prohibited; various religious houſes, in all parts of his dominions, were ſuppreſſed; all Auſtrian, Hungarian, and Lombard biſhops were enjoined never to accept the dignity of cardinal; all ſubordination to the holy ſee in ſecular affairs was diſclaimed, and many other vigorous ſteps towards a complete emancipation were purſued. Theſe proceedings excited the greateſt alarm in the breaſt of Pius VI. At firſt he hoped that ſome oppoſition would be made to ſuch innovations by the imperial ſubjects themſelves; and he was encouraged in that hope by the ſtrong remonſtrances which were ſent to the emperor, from the clergy of Brabant, Flanders, and Lombardy. They, however, produced no effect on Joſeph, who perſiſted in his ſchemes, ſupported by the aſſiſtance of the lay magiſtrates and the military power. Even the archduke Ferdinand, his brother, had been nearly deprived by him of the government of Lombardy, for ſeconding the remonſtrances of the Milaneſe clergy. Under theſe circumſtances, his holineſs thought it high time to remonſtrate himſelf againſt the imperial meaſures, and directed his nuncio at the court of Vienna to preſent the moſt preſſing ſolicitations to his majeſty, that he would conſider the conſequences of his proceedings. But theſe produced no effect whatever, and the prince Kaunitz told him, that

that his master was fully aware of the effects of what he had done, and was determined to carry into execution all the edicts that he had issued.

The thunders of the Vatican were no longer objects of terror, and of this Pius VI. was fully aware; he therefore resolved to try whether his personal entreaties might not have the effect of prevailing with the emperor to desist from his hostile purposes. He accordingly determined to visit that prince at Vienna. This determination was highly disapproved by the members of the sacred college; Pius was, however, resolute, saying that he had rather submit to humiliation in his dignity than remorse in his conscience. At that time, inauspicious as his prospects were, he little thought of the afflictions that were in reserve for him in another quarter, and from another power then on the best terms with the papal see.

The pope, after the fatigues of a winter's journey over the Alps, arrived at Vienna in March 1782, where he was received by the emperor with every mark of external respect, and who treated him with the same distinction as if he were in possession of that vast power which his predecessors had enjoyed, and was reigning in his own capital. The emperor and pope had repeated conferences on the subject of the changes which Joseph was making in ecclesiastical matters; but the arguments of Pius were not sufficiently strong to induce the emperor to repeal any of his late edicts, and he could only obtain a respite for some religious foundations which were threatened with dissolution. While Pius continued at the Austrian capital, he is said to have received several Protestant princes, noblemen, and clergy, with the greatest affability; and it has been likewise asserted, but upon no proper evidence, that he converted to the Catholic religion many thousand Protestants, who had come to Vienna for the purpose of seeing him perform the duties of his high office on Easter Sunday. After the pope's return from his visit to Vienna, he employed much of his time in the improvement of his temporal dominions, and in the enriching and aggrandizement of his own relations. One nephew he made a cardinal, and another he raised to the dignity of a ducal coronet, circumstances that created much disaffection to his government from the people, who saw them grow wealthy by the plunder of the estates belonging to the apostolical chamber, and the most opp ressive public spoliations. In the mean time he was invol ved in new disputes with the court of Naples, which, encouraged by the example of the emperor, had abolished some of the perogatives that the court of Rome had for ages been accustomed to exercise in the Neapolitan dominions, as well as the singular custom of delivering a white horse to his holiness on St. Peter's day, as a token of feudal vassalage to the holy see. In 1787 the matter was carried much farther, and the king of Naples absolutely prohibited any appeal from his decisions to the court of Rome, and at one blow abolished for ever certain feudal homages which he conceived as disgraceful to his own dignity any longer to submit to. When the pope heard of these proceedings, he issued a solemn protest against the innovations made by them on the sovereignty of the holy see over the kingdom of Naples. He sent his internuncio to Naples with certain apostolical bulls; but the decrees produced no effect, and the messenger of them was banished the kingdom of Naples. This was in the autumn of the year 1788, at a time when Pius had a misunderstanding with the grand duke of Tuscany, respecting some innovations of the bishop of Pistoia; this at length changed into a violent quarrel, in which the grand duke undertook to annihilate the spiritual power of the pope in his dominions, and to counteract his supremacy in the hierarchy of the state. The effects of a similar spirit were manifested by the Venetian republic, the senate of which had, in the early part of this pope's reign, secularized a number of abbeys, and other rich establishments, and incorporated them with those belonging to the nobility. On account of these proceedings, the pope had threatened them with the effects of his apostolical anger, and even gone so far as to talk seriously of compelling them to obedience, by the force of temporal arms. This quarrel had at one time been appeased, by the intervention of certain cardinals, but the senate continued in its laudable labours of suppressing and reforming conventual houses in favour of hospitals and other charitable establishments, without paying any regard to the murmurs and complaints of the pontiff. The duke of Modena, likewise, without the concurrence of the holy see, suppressed the inquisition in his state, and was preparing, if it should appear necessary, to arm against the pope in defence of certain territorial rights. After all, these were the commencement of evils, and of no sort of consequence, compared with what Pius VI. was on the point of enduring from revolutionary France. In that country, before the assembling of the states-general, a disposition was shewn by many of the higher clergy to introduce reforms in matters of an ecclesiastical nature, without any application for the concurrence of the holy see. The French government, likewise, without communication with the court of Rome, had suppressed the order of the Celestines in France, and seized upon the estates of those of the same order, who, living under the Roman jurisdiction at Avignon, had property in the French territory. These circumstances filled the heart of Pius VI. with an overwhelming anxiety, which was augmented by the edict that was passed in favour of the Protestants, granting them a civil existence, and legitimating their children. Pius was urged by some of the members of the sacred college to adopt violent measures in defence of his dignity and just right; but he preferred moderate measures, and was contented to mourn in silence over these daring attacks upon his office, and that toleration of heretics which threatened ultimate ruin to the Catholic church.

In the following sketch we shall be as brief as possible, and endeavour to omit every circumstance that is not connected with the subject of the present article. The downfall, however, of the papal authority is of too great importance to the world to be lightly passed over: that power that tyrannised over the consciences and temporal rights of mankind for many centuries, so that to have lived to behold its humiliation and almost entire destruction, is no small privilege of the existing generation.

After the states-general in France had assembled in 1789, one of the first abuses which was the object of public attention, and which, it is believed, the court even had previously resolved to sacrifice, was the payment of ecclesiastical tribute to Rome, under the form of bulls, dispensations, and other objects of spiritual traffic. This was followed by a decree of the National Assembly, at the close of the year, declaring the church estates to be national property, which filled the court of Rome with general consternation. At length the pope's temporal possessions in Vennaissin and Avignon were confiscated by the National Assembly. Against this seizure of his property, briefs and bulls were issued by the pope; and the partizans for his holiness, and the friends to the French revolution in the country which was the object of dispute, carried on against each other what was called a *civil*, but a bloody contest. At length the revolutionists of Avignon gained the ascendancy; and after dethroning the archbishop, and dispersing the clergy for refusing to

take

take the civic oath, they depofed the pope from his fovereignty, feized his revenues, and Avignon, with the whole of the papal territory in France, was converted into republican departments. When the National Affembly had formed their civil conftitution for the clergy, the pope was folicited by the anti-conftitutionalifts, with the abbè Maury at their head, to fuppress it by an apoftolical bull. Accordingly he difpatched, with this view, his celebrated monitory of the 13th of April, 1791. But this inftrument, fo formidable in former times, now ferved no other purpofe than to excite ridicule, increafe the feverity of the proceedings againft the non-conforming clergy, and to excite popular odium againft his holinefs. In Paris it was regarded as the tocfin for a civil war, and the mob, without hefitation, to exprefs their refentment againft the power which iffued it, burnt the effigy of the pope, in all his pontifical infignia, in the garden of the Palais Royal.

The hoftility of the court of Rome to what was tranfacting in France was not confined to briefs and bulls, but was difplayed in profecutions againft fuch perfons as were fufpected of any attachment to the revolution which had taken place. Several officers, natives of France, but in the pope's employ, were degraded, and fent to the gallies, for having difcovered fentiments favourable to the new order of things. A kind of profcription, likewife, was begun againft every thing or perfon which bore the name of French or Frenchman, till it was fufpended in confequence of the interference of the executive council of the French republic, which threatened hoftilities, if redrefs were not inftantly obtained. After the appearance of the *famous* manifefto iffued by the duke of Brunfwick of the coalition of crowned heads, againft the French republic, menacing with extermination all who fhould dare to refift the forces employed in maintaining the caufe of royalty, military preparations were begun to be made in the papal dominions, which could not but be confidered by the French government as intended to ftrengthen the power of their enemies. This fufpicion was confirmed by the circumftances connected with, and immediately following the murder of Baffeville, the French ambaffador, by the mob of Rome. That minifter had been fent, in 1793, to diffuade the pope from joining the league againft the republic, and had been inftructed to erafe the royal arms from the French academy, and all public buildings belonging to the nation, and to fubftitute the republican infignia in their place. Pius, however, refufed to acknowledge him as the reprefentative of France, till a reparation had been made to the holy fee for its wrongs. Baffeville being prevented from difplaying on the public buildings the emblems of his own government, determined to maintain its honour in his own perfonal appearance, and without hefitation openly paraded the ftreets with the national cockade in his hat. He had not worn it many days before he was affaffinated in the ftreets. This deed was condemned in very gentle terms by the pope, who probably was not grieved at what had happened; inftead, therefore, of making conceffions, and endeavouring to difcover and punifh the perpetrators of the act, he openly declared againft the French republic. His manifefto, which ordered a general armament, avowed the intention of affifting to exterminate the fworn enemies of all thrones and altars. The manifefto offered alfo amnefty and abfolution to criminals who fhould take up arms for the church and ftate, and exempted no perfons from the rifing in mafs but children, old men, and priefts, "who were to raife up their hands on the mountain, while the faithful fought in the plain." The pope, for want of money, was unable to keep his army together, and in a very fhort time he was glad to change his tone, and to declare himfelf neutral; he had not, however, wifdom and prudence fufficient to be fteady in his neutrality. In 1796, when Bonaparte was every where victorious, Pius committed an act of aggreffion by fuffering the Neapolitan cavalry who were haftening to their fuccour to pafs through the territories of the church, and even directed their march. No fooner had the conqueror difperfed the Auftrian armies in Italy, than he proceeded againft thofe Italian ftates which had either joined or favoured them. Having with his main army entered the territory of the pope, and without refiftance taken poffeffion of Bologna, Ferrara, and Urbino, the pontiff was under the neceffity of throwing himfelf on the clemency of the conqueror, who would not even grant him an armiftice but on very fevere conditions. By the terms of it, the pope was compelled to fet at liberty thofe perfons who were at that time confined for their political conduct or opinions, to renounce the friendfhip of the coalefced powers, and to fhut up his ports againft them; to furrender to the French the cities of which they already had poffeffion, as well as the citadel of Ancona, to pay nearly a million fterling, and to deliver one hundred pictures, bufts, vafes, ftatues, &c. and five hundred manufcripts, to be felected by commiffioners who fhould be fent to Rome for that purpofe. When the terms of peace came to be difcuffed, the pope refufed to accede to thofe conditions to which he had agreed when the armiftice was concluded.

The court of Rome had now the temerity to refolve trying the fortune of its arms againft thofe of France, having been promifed the affiftance of a confiderable body of troops by the court of Vienna. Every effort was now made by the pope, but he was ill-feconded by his fubjects, many of whom were more anxious to welcome the French to Rome than prevent their arrival. The crifis foon arrived which brought affairs to an iffue, and expofed the fatal policy which had directed the determination of the papal cabinet. A feries of ill fuccefs obliged his holinefs to confirm all the conditions of the armiftice without referve; to admit the annexation of Avignon and Vennaifin to the French republic; and he likewife confented to pay thirty millions of livres, as well as to furnifh the French army with 16,000 horfes, by way of ranfom for the remnant of his dominions which he was permitted to retain. By this peace the political exiftence of the holy fee was prolonged for a fhort time, but it was left in a ftate of extreme embarraffment: and the pope, who had already demanded of his fubjects the half of their plate, was now obliged to call upon them for the remainder, requefting that it might be brought into the pontifical treafury within three days. This requifition produced much difcontent and murmuring among the people, and ftrong fymptoms of a revolutionary fpirit were difcoverable in all parts of the ecclefiaftical ftate. The popular odium was particularly manifefted againft the duke of Brafchi, on whom was lavifhed every expreffion of indignation and contempt. To check and reftrain thefe tokens of public hatred and difaffection, the government of the court of Rome became fevere and tyrannical. To overawe the people a ftrong garrifon was placed in the caftle of Angelo, and foldiers were diftributed in different quarters of the city. Thefe feverities directed the public refentment againft the pope, who could never appear abroad without receiving the ftrongeft marks of difapprobation. Political confpiracies were every day forming, and in this diftracted fituation of affairs Jofeph Bonaparte, the brother of the general, arrived at Rome in the quality of ambaffador from the French republic. This was highly acceptable to thofe who were planning a change in the government, and towards the end of December 1797, an infurrection broke out, attended with very

difaftrous

diſaſtrous circumſtances, in conſequence of which the French ambaſſador quitted Rome, and retired to Florence. In the commotion the French general Duphot had been moſt inhumanly murdered, of which the directory at Paris made a handle for ſeizing the remaining treaſures of the ancient metropolis of the world, and for aſſuming the glory, if ſuch it could be denominated, of erecting the Gallic ſtandard on the Capitol. Orders were inſtantly given for the march of the French and Ciſalpine forces to Rome. To deprecate, if poſſible, the wrath of the French government, and ward off the fatal blow, ſolicitations were made for the mediation of the Spaniſh ambaſſador, and that of the courts of Naples; Florence, and Vienna. The intervention of heaven was alſo ſought by prayers, faſtings, proceſſions, and jubilees. The theatres were ſhut up ; and new and numerous arreſts of ſuſpected perſons were ordered to be made. In contempt of theſe acts of government, the revolutionary party covered the walls with ſatirical and menacing placards ; and they alſo diſtributed among the people portraits of Bonaparte, with the title of the new ſaviour of the world. In the mean time the French and Ciſalpine armies, under the command of general Berthier, marched to Rome, preceded by a proclamation, in which the general declared that the only object of his viſit was the puniſhment of the murderers of Duphot and Baſſeville, and that the people of Rome ſhould find in the French army protectors and friends. The revolutionary party, encouraged by this proclamation, actually proclaimed the Roman republic on the 15th of February 1798. Pius, however, reſolved to make one more effort to preſerve the government of the holy ſee from annihilation, and ſent to Berthier, who was encamped without the walls of the city, his cardinal-vicar and other deputies, accompanied by the Neapolitan miniſter, who were inſtructed to negociate for the continuance of his temporal exiſtence, by the further ſacrifices of provinces and of millions. His hopes were quickly diſſipated by the peremptory refuſal of the general to admit any other deputation than that of the Roman people. As the ſtorm was approaching, ſome of the cardinals prudently fled from the city, but the majority waited the event, hoping, no doubt, to retain their rank and poſſeſſions, though probably at the expence of conſiderable ſacrifices. For a ſhort time they were treated with forbearance, but were obliged formally to abdicate their authority. After this, their eſtates were confiſcated for the benefit of the nation, while the cardinals themſelves were included under one common proſcription, and confined as priſoners in a convent at Rome. From this priſon they were ſent to one, not ſo commodious, at Civita-Vecchia, where they were ſubjected to ſuch menaces and inſults, that the greater part of them were glad to purchaſe their liberty by the ſacrifice of all their wealth. In the mean time the pope remained confined to his apartments at the Vatican, in anxious and trembling uncertainty with reſpect to his fate. That of his nephews, already mentioned, had been decided. The cardinal was a fellow ſufferer with the other members of the ſacred college, and the eſtates of the duke of Braſchi were confiſcated to the public uſe. His magnificent and ſumptuous furniture, his pictures, engravings, antiquities, and his muſeum, were brought to the hammer. The eſtates and property of the pope himſelf were involved in the ſame confiſcation with thoſe of the cardinals : and the French commiſſaries, judging that his preſence, in Rome, was incompatible with the tranquillity of the ſtate, decreed that he ſhould be ſent beyond the boundaries of the Roman territory. Pius VI. was now eſcorted by a body of French cavalry to Sienna, where his firſt reſidence was in the convent of St. Barba, which he was obliged to quit by an earthquake that overthrew the apartments adjoining to thoſe which he occupied, and damaged thoſe in which he was. He now took up his abode within the walls of the city. In the month of May, he removed to a Carthuſian convent within two miles of Florence. In this retired place Pius kept his little court, with great circumſpection, to avoid giving umbrage either to the French or Tuſcan government. He even offered to leave the nomination and regulation of his houſehold to the inſpection of the French miniſter. It was ſcarcely poſſible for papal humiliation to be carried much farther, for this miniſter happened to be a Proteſtant of the Lutheran perſuaſion. But ſtript of his pontifical dignity, Pius is ſaid to have exhibited an excellent example of chriſtian-like reſignation. He ever expreſſed a meek and forgiving diſpoſition towards thoſe who had deſpoiled him of his power and authority. Unembarraſſed by the cares of government, his health became more ſtable, his ſpirits increaſed, and adverſity ſeemed to prove to him the true road to happineſs. He was not, however, allowed to enjoy the bleſſings of this ſtate of humble retirement ; the French directory enjoined the grand duke to diſmiſs him from the Tuſcan territory : and it was decided by the republican tyrants that he ſhould be ſent to the iſland of Sardinia, where a papal conſpiracy, if ſuch an event ſhould happen, muſt neceſſarily be circumſcribed within very narrow bounds, but the attack of ſerious illneſs made his removal impoſſible. After his health was reſtored, he was permitted to remain in peace in the Carthuſian convent, till the renewal of the war between France and Auſtria which had been terminated by the peace of Campo Formio, when it was reſolved that he ſhould be removed into the interior of France. In the courſe of a long and painful journey, frequently expoſed to the inſults of the illiberal and unfeeling, who could not but exhibit ſigns of exultation in the deſtruction of the papal power, he caught a feveriſh diſorder which put an end to his ſufferings on the 29th of Auguſt, 1799, being in the 82d year of his age. The French directory refuſed to his remains the accuſtomed ſepulchral rites, but upon a change in the government of that country, the conſuls of the republic ordered that he ſhould be buried, with the honours commonly due to a perſon of his rank, and that a ſimple monument ſhould be erected over the place of his interment, with an inſcription expreſſive of the dignity which he bore. In 1802 his ſucceſſor, Pius VII., obtained permiſſion to remove his body to Rome.

"Pius VI." ſays the excellent writer of his article in the General Biography, to whom we have very frequently referred in our own, "though poſſeſſed of many eſtimable qualities as a private man, had few of thoſe talents which are neceſſary to govern in times of difficulty and danger. Yielding often to the impulſe of the moment, the impetuoſity of his character led him into ſome errors, which were followed by a ſpeedy repentance. Preſumptuous with reſpect to his own opinion he was blind to the future, where men of common ſagacity had the cleareſt foreſight; and filled with ideas of the importance and dignity of his office, he prepared for himſelf many mortifications and inſults, which he had neither the addreſs to avoid, nor the power to avenge. As the viſible head of the church, his attention to the duties of his ſtation was uniform and exemplary, and his piety, though oſtentatious, was devoid of hypocriſy or fanaticiſm, and his morals were pure and irreproachable. In his youth he had been one of the handſomeſt men of his time. To a very lofty ſtature he joined a noble and expreſſive ſet of features, a benign countenance, a ſonorous voice, and an elegant engaging manner. Of theſe advantages he was but too ſenſible, and he betrayed a puerile vanity in diſplaying them on all public occaſions, which expoſed him to to many bitter ſarcaſms, and which the ſeriouſly devout were at a loſs to reconcile with the acknowledged ſanctity and gravity of his character." See alſo New Ann. Regiſter. Monthly and Gent. Mag.

We beg leave, in this place, to correct an error in the article Lewis XVI., vol. xx., in which the daughter of that unfortunate monarch is mentioned as having died in 1796. She was, we are happy to ſay, living, at that time, in London; pitied and reſpected for her misfortunes, and honoured and beloved on account of her many virtues.

PIUZANO, in *Geography*, a town of Italy, in Friuli; 14 miles W. of Gemona.

PIX, in *Coinage*, a box, in which a ſmall proportion or ſample of the coins ſtruck at the mint is reſerved, in order to be aſſayed and compared with a check-piece or ſtandard kept in the exchequer for the occaſion. This operation, which is called the "trial of the pix," is performed with great exactneſs in the preſence of the privy council, the officers of the mint, and a jury of the goldſmiths' company; and there is no inſtance upon record of the coins thus tried being found to vary from the full ſtandard.

PIXITES, in *Ancient Geography*, a river of Aſia, in the Colchide, towards the north of the town called Trapezus.

PIZARRO, Francisco, in *Biography*, the diſcoverer and conqueror of Peru, was the natural ſon of a Spaniſh gentleman by a woman of the loweſt rank. His father, not thinking himſelf bound to raiſe him to a condition ſuperior to his maternal birth, not only left him deſtitute of all education, but employed him in the ſervile office of keeping ſwine. Indignant at this treatment, he ran away and enliſted as a common ſoldier. After ſerving ſome time in Italy, he joined the adventurers who were embarking at Seville for America. He was preſent in all the wars of Cuba and Hiſpaniola, and upon every occaſion he ſtood pre-eminent for undaunted courage, perſeverance, and enterprize, and was in a ſhort time conſidered as fully qualified for command. His mind and body were equally adapted for difficult and laborious undertakings, and experience had prepared him to meet all emergencies. In 1524, having acquired ſome property, he, with Diego de Almagro, and Hernando Luque, entered into an aſſociation for the conqueſt of the ſuppoſed rich countries on the coaſt of the South ſea. Pizarro made the firſt attempt. He failed in November from Panama in a ſingle veſſel with 112 men, ſo feeble were the means by which the ſubverſion of a great empire was to be effected. (See Peru.) Pizarro made ſeveral voyages, and with his aſſociates acquired the moſt important conqueſts, till at length the conquerors quarrelled among themſelves, and in April, 1538, the two hoſtile parties of Spaniards, each bearing the royal ſtandard, met and engaged with all the fury of inveterate foes, while an immenſe multitude of Indians, who had borne the cruelties of both, aſſembled on the ſurrounding mountains, enjoying, to them, the edifying ſpectacle of their ſavage foes deſtroying each other by mutual ſlaughter. The battle was fatal to the cauſe of Almagro, who was himſelf taken priſoner after the total and bloody defeat of his troops. In a very ſhort time the mercileſs Pizarro brought his old aſſociate to trial, condemned and executed him. Afterwards Pizarro was the unrivalled maſter of theſe extenſive regions, and without any regard to the Spaniſh court, he divided them like a conqueror among his followers, ſetting apart the moſt valuable lots for himſelf, his brothers, and favourites. His partiality excited much diſcontent among perſons, all of whom were actuated by the thirſt of gain. The partizans of Almagro ſighed in ſecret for revenge; but as no open hoſtility was manifeſted, the plan of diſcovery was carried on with vigour, and Gonzalo Pizarro was diſpatched by his brother upon the arduous enterprize of croſſing the Andes, and exploring the countries to the eaſt of that chain. It was on his return to Quito that he learnt the deſtruction of his brother. The followers of Almagro had repaired in great numbers to Lima, where the ſon of their late chief received them with much kindneſs, and engaged their warmeſt attachment by his popular qualities. In their private meetings a conſpiracy was formed againſt the life of Pizarro. He was apprized of the fact, but, in the confidence of uncontrolled power, he diſregarded them. The plot was, however, matured; and on the 26th of June 1541, at mid-day, a time, in thoſe hot climates, devoted to repoſe, Herroada, one of the principal of the Almagrian officers, at the head of eighteen determined aſſociates, ſallied out armed from Almagro's houſe, and proceeded to the palace. They paſſed unobſerved through the outer courts, and were arrived at the foot of the ſtaircaſe before an alarm was given. Pizarro was in a large hall with ſome friends. One of theſe who came to the top of the ſtairs to enquire into the cauſe of the tumult, was laid dead, while others eſcaped through the windows. The conſpirators ruſhed into the hall; Pizarro, with his half brother Alcantara, was killed, and the others mortally wounded: the former defended himſelf till he was abſolutely exhauſted with fatigue, when, unable any longer to parry off the weapons, he received a thruſt full in the throat, fell, and expired. His memory lives and ever will live as a ſignal contributor to his country's aggrandizement, but blackened with the ſtain of atrocious cruelty and perfidy. Univer. Hiſt. Robertſon's America.

PIZOLO, in *Geography*, a town of Sicily, in the valley of Noto; eight miles S. of Modica.

PIZZATI, Giuseppe, in *Biography*, publiſhed at Venice in folio, with a ſeparate volume of plates, in 1782, a treatiſe "On the Science of Sounds and of Harmony:" "La Scienza de' Suoni, e dell' Armonia." The author clearly explains the phenomena of ſound, as far as concerns practical muſic, from d'Alembert, another modern writer on harmonics, and gives an account of late diſcoveries in the ſcience, and of the ſyſtems of Rameau and Tartini, from Rouſſeau, explaining the laws of harmony in their preſent uſe.

PIZZICATO, in *Italian Muſic*, from *pizzicare*, to pinch, is a term that announces to the performers on bowed inſtruments the uſe of the fingers inſtead of the bow. When the bow is to be reſumed, it is expreſſed by the words *con arco*.

PIZZIGHITONE, in *Geography*, a town of Italy, in the department of the Upper Po, on the Adda; nine miles N.W. of Cremona. N. lat. 45° 10'. E. long. 9° 48'.

PIZZO, a town of Naples, in Calabria Ultra, near the coaſt; 13 miles N.E. of Tropea.

Pizzo *Ferrato*, a town of Naples, in Abruzzo Citra; 13 miles E.S.E. of Sulmona.

Pizzo *di Gotto*, a town of Sicily, in the valley of Demona; ſix miles S. of Melazzo.

PLA, a town of Spain, in the province of Catalonia; five miles S. of Urgel.

PLABENNEC, a town of France, in the department of the Finiſterre, and chief place of a canton, in the diſtrict of Breſt; ſeven miles N.E. of Breſt. The place contains 3255, and the canton 11,833 inhabitants, on a territory of 230 kiliometres, in 12 communes.

PLACAGNODIAUGIA, in *Natural Hiſtory*, the name of a genus of ſpars.

The word is derived from the Greek πλαξ, *a cruſt*, αγνος, *pure*, and διαυγης, *pellucid*.

The bodies of this genus are cryſtalline terrene ſpars, or ſparry bodies with much of the brightneſs and tranſparence of of cryſtal, but debaſed by an admixture of earthy matter, and are imperfectly pellucid, and formed into thin plates with flat ſurfaces, but covered at times, either in part or entirely, with tubercles or botryoide prominences, and are compoſed of arrangements of oblong concretions, of no determinately angular figure.

Of this genus there are only two known ſpecies, *viz.* a hard ſemipellucid and yellowiſh-brown one, and a brittle pellucid and whitiſh one. Hill.

PLACAGNOSCIERIA, the name of a genus of ſpars.

The word is derived from the Greek πλαξ, *a cruſt*, αγνος, *pure*, and σκιερος, *opaque*.

The bodies of this genus are dull and opaque cryſtalline terrene ſpars, formed into cruſts, and of an irregular and not ſtriated texture within.

Of this genus there are three known ſpecies, *viz.* a hard whitiſh-brown one, a dull crumbly whitiſh one, and a dull pale brown friable one, of a very coarſe texture, which encruſts the ſides and bottoms of veſſels, in which water is frequently boiled. Hill.

PLACANICA, in *Geography*, a town of Naples, in Calabria Ultra; 27 miles E.S.E. of Reggio.

PLACARD, or Placart, *Placaert*, a foreign term, frequent in gazettes, ſignifying a leaf, or ſheet of paper, ſtretched and applied upon a wall, or poſt. Edicts, regulations, &c. are to be made public in placards.

The word placard is alſo uſed for a libel or lampoon. At Rome, placards againſt the pope are frequently fixed, in the night-time, to the ſtatue of Paſquin. See Pasquinade.

Placard, in *Architecture*, denotes the decoration of the door of an apartment, which is ſometimes a corniche ſupported by conſoles.

Placard, in our *Cuſtoms*, denotes a licence whereby a perſon is permitted to ſhoot with a gun, or to take otherwiſe unlawful game.

PLACCIUS, Vincent, in *Biography*, a learned juriſt, was born at Hamburg in the year 1642. After ſtudying at Leipſic, and other places, he travelled into Italy and France, and became a licentiate in law at Orleans. Returning to his native city, he practiſed at the bar; and in 1675, was appointed profeſſor of moral philoſophy and eloquence, the duties of which he performed till his death, in 1699. He was author of a volume of Latin poems, and of many other works, of which the principal are, 1. A curious bibliographical piece concerning anonymous writers, firſt publiſhed at Hamburg in 1674, under the title of "De Scriptis et Scriptoribus anonymis atque pſeudonymis Syntagma;" together with the "Catalogus Auctorum ſuppoſitiorum" of Rhodias. The work was well received, and he prepared a new edition of it, with conſiderable additions, which was printed after his death, in 2 vols. folio, in 1708, under the care of John Albert Fabricius. A ſupplement to it was publiſhed by Mylius, in 1740, at Hamburg. 2. "De Arte Excerpendi," 1689. Placcius has always been eſteemed a learned and able writer, but his ſtyle is ſaid to be obſcure, and occaſionally confuſed. Moreri.

PLACE, Peter de la, a learned French magiſtrate, and various writer, was born at Angoulême in the year 1526. He applied with ſucceſs to the ſtudy of juriſprudence, and in 1548 publiſhed a Latin paraphraſe on the Titles of the Imperial Inſtitutes, "De Actionibus, Exceptionibus et Interdictis," in 4to. After this he was called to the bar of the parliament of Paris, and pleaded with ſo great ſucceſs, that he acquired the character of a learned, eloquent, and virtuous counſellor. Francis I. appointed him advocate of his court of aids at Paris, and he diſcharged the duties of that office with ſo much talent and integrity, that Henry II. nominated him his firſt preſident in the ſame court. It was believed that he was a convert to the Proteſtant religion in the year 1554, but he did not make an open profeſſion of it till the death of Francis II. On the breaking out of the civil war, he retired to one of his houſes in Picardy; but upon the concluſion of peace in 1562, he ſeized the earlieſt opportunity of vindicating himſelf before the king from the ſeveral charges which had been preferred againſt him. He was now appointed by the prince of Condé ſuperintendant of the houſhold; and upon the rupture of that prince with the court, about the year 1566, M. La Place retired to the caſtle of Vé in the Valois, where he continued after the death of the prince, till Charles IX. granted the Proteſtants advantageous terms of peace in 1569, with the deſign of the more eaſily extirpating them. La Place, deceived by royal treachery, returned to Paris, and reſumed the office of preſident to the court of aids, which he retained till he fell a victim in the horrible and accurſed maſſacre of the Proteſtants, on St. Bartholomew's day, in the year 1572, at the age of 46. He is ſaid to have poſſeſſed great ſoundneſs of judgment, clearneſs of diſcrimination, and a truly philoſophic ſpirit, which admirably qualified him for the office of magiſtrate, and which were ſeldom found united in the profeſſional men of that time. His chief works are, "Commentaries on the State of Religion, and of the Commonwealth, from 1556 to 1561;" "A Treatiſe on the right Uſe of Moral Philoſophy in connection with the Chriſtian Doctrine;" and "A Treatiſe on the Excellence of the Chriſtian Man." Moreri.

Place, *Locus*, in *Philoſophy*, that part of immoveable ſpace which any body poſſeſſes.

Ariſtotle, and his followers, divide place into *external* and *internal*.

Place, *Internal*, is that ſpace, or room, which the body contains.

Place, *External*, is that which includes or contains the body; which is alſo called, by Ariſtotle, the firſt or concave and immoveable ſurface of the ambient body.

It is controverted, in the ſchools, whether internal place be a real entity, or only an imaginary being; *i. e.* whether it be any thing intrinſically, or only an aptitude and capacity of receiving bodies.

Some maintain it a poſitive being, incorporeal, eternal, independent, and infinite; and aſſert it even to conſtitute the immenſity of the godhead.

The Carteſians, on the contrary, hold internal place, abſtractedly conſidered, to be no other than the very extenſion of the bodies contained in it; and therefore in no wiſe different from the bodies themſelves.

The ſchoolmen likewiſe diſpute, whether external place be moveable, or immoveable? Its immobility is argued from this conſideration; that what moves, muſt neceſſarily leave its place; which it cannot do, if it go along with the moveable. Others charge an abſurdity on this opinion of Ariſtotle; *viz.* that hence it follows, that a body really at reſt is continually ſhifting place: a tower, for inſtance, on a plain; or a rock in the middle of the ſea; becauſe the one and the other, continually incloſed with new air, or new water, muſt be ſaid to be in motion or to change place.

To ſolve this difficulty, and ward off the abſurdity which follows from Ariſtotle's laying down external place as immoveable, many expedients have been had recourſe to. The Scotiſts contend for place's being only immoveable, by equivalence. Thus, when the wind blows, the air which inveſted

vested the surface of the tower does indeed recede, but then other similar and equivalent air takes place. The Thomists choose to deduce the immobility of external place, from its keeping the same distance from the centre, and the cardinal points of the world; and the Nominalists, from a correspondence with certain virtual parts of the divine immensity.

The Cartesians deny external place to be either a surrounding surface, or a body surrounded, or a mean term between the two; and conceive it to be the situation of a body among adjacent bodies considered as at rest. Thus the tower shall be deemed to remain in the same place, though the ambient air be changed; since it retains the same situation with regard to the neighbouring hills, trees, and other parts of the earth.

Sir Isaac Newton better, and more intelligibly, distinguishes place into *absolute*, and *relative*.

PLACE, *Absolute*, and *primary*, is that part of infinite and immoveable space which a body possesses.

PLACE, *Relative*, or *secondary*, is the space it possesses, considered with regard to other adjacent objects.

Dr. Clarke adds another kind of relative place, which he calls *relatively common* place; and defines it, that part of any moveable or measurable space which a body possesses; which place moves together with the body.

PLACE, Mr. Locke observes, is sometimes likewise taken for that portion of infinite space possessed by the material world, though this, he adds, were more properly called extension.

The proper idea of place, according to him, is the relative position of any thing, with regard to its distance from certain fixed points; whence we say, a thing has or has not changed place; when its distance is, or is not altered with respect to those bodies.

For the vision of place, see VISION, and VISIBLE.

PLACE, in *Optics*, or *Optical Place*, is the point to which the eye refers an object.

Thus the points D and E (*Plate* XVII. *Optics*, *fig.* 11.) to which two spectators in *d* and *e* refer the object C, are called *optic places*.

Here, if a right line joining the optic places D and E, be parallel to a right line passing through the eyes of the spectators *d*, *e*; the distance of the optic places D, E, will be to the distance of the spectators *d* and *e*, as the distance of one of the optic places from the place of the object E C, to the distance of the other spectator from the same object *d* C.

PLACE, *Optic*, of a star, is a point in the surface of the mundane sphere, as C or B (*Plate* XVIII. *Astronomy*, *fig.* 4.), wherein a spectator in E, or T, sees the centre of the star S.

This is divided into *true* and *apparent*.

PLACE, *True*, or *real optic*, is that point of the surface of the sphere B, in which a spectator, placed in the centre of the earth, sees the centre of the star, or phenomenon. Or, it is a point among the fixed stars, determined by a line drawn from the centre of the earth through that of the star, and terminated in B among the stars.

PLACE, *Apparent*, or *visible optic*, is that point of the surface of the sphere, in which a spectator, placed on the surface of the earth in E, sees the centre of the star S. Or, a point C found by a line passing from the spectator's eye through the star, and terminated in the sphere of the stars.

The distance between the two optic places makes what we call the *parallax*.

The *apparent* place, in optics, is different from the *real* one; for when, by refraction through glasses, that parcel of rays which falls on the pupil of the eye, from each point of any near object, is made to flow as close together, as that which comes from a distant one; or when, by the same means, the rays coming from distant objects are made to diverge as much as if they flowed from near ones; then the eye must necessarily see the place of the object changed; which change is its apparent place.

If an object be placed nearer to a convex glass than is the distance of its focus, its apparent place may be determined; but if the object be in the focus of the glass the *locus apparens* of the object cannot be determined; only that it will appear vastly remote.

Nor can the *locus apparens* be determined if the object be beyond the focus of the convex glass; but if the object be farther distant from a convex glass than its focus, and the eye lie beyond the distinct base, its apparent place will be in the distinct base. See LENS.

PLACE *of the sun*, a *star*, or *planet*, simply, denotes the sign and degree of the zodiac, which the luminary is in.

Or, it is that degree of the ecliptic, reckoned from the beginning of Aries, which the planet's or star's circle of longitude cuts; and therefore it coincides with the longitude of the sun, planet, or star.

As the sine of the sun's greatest declination $23° 30'$: to the sine of any present declination given or observed, *v. gr.* $23° 15'$ :: so is radius 10 : to the sine of his longitude $80° 52'$, which, if the inclination were north, would give $20° 51'$ of Gemini, if south, $20° 52'$ of Capricorn, for the sun's place.

PLACE, *Astronomical*. See ASTRONOMICAL.

PLACE, *Moon's*, is that point of her orbit in which she is found at any time.

This, by reason of the great inequalities in the lunar motions, which render a number of equations and reductions necessary before the just point be found, is of various kinds.

PLACE, *Excentric*, of a planet in its orbit. See EXCENTRIC, and P, *Plate* XVI. *Astron. fig.* 148.

PLACE, *Heliocentric*, of a planet. See HELIOCENTRIC, and R, *fig.* 148.

PLACE, *Geocentric*. See GEOCENTRIC, and R, *fig.* 148.

PLACE *of Radiation*, in *Optics*, is the interval, or space in a medium or transparent body, through which any visible object radiates.

PLACE, in *Geometry*, is a line used in the solution of problems; more usually called by the Latin name *locus*.

See the doctrine of geometrical places under LOCUS.

PLACE, in *War*, is a general name for all kinds of fortresses, where a party may defend themselves.

In which sense it may be defined to be a place so disposed, as that the parts which encompass it defend and flank one another.

PLACE, *Strong*, or *fortified*, is a place flanked and covered with bastions. See FORTIFIED *Place*.

PLACE, *Regular*, is that whose angles, sides, bastions, and other parts are equal; and this is usually denominated from the number of its angles; as a pentagon, a hexagon, &c. Palma Nova, built by the Venetians, is a dodecagon.

PLACE, *Irregular*, is that whose sides and angles are unequal.

PLACE *of Arms*, in *Fortification*, is a strong city or town, pitched upon for the chief magazine of an army.

PLACE *of Arms*, in a city or garrison, is a large open spot of ground, usually near the centre of the place, where the grand guard is commonly kept, and the garrison holds its rendezvous at reviews, and in cases of alarm, to receive orders from the governor.

PLACE *of Arms*, of an attack, in a siege, is a spacious place covered from the enemy by a parapet or epaulement, where

where the foldiers are pofted ready to fuftain thofe at work in the trenches, againft the foldiers of the garrifon. It is cuftomary to make three places of arms, when the ground will permit; the firft and moft diftant from the place is about three hundred toifes from the glacis of the covert way; the fecond is within one hundred and forty toifes; and the third at the foot of the glacis. See PARALLELS.

PLACE *of Arms particular*, in a garrifon, is a place near every baftion, where the foldiers, fent from the grand place to the quarters affigned them, relieve thofe that are either upon the guard, or in fight.

PLACE *of Arms without*, is a place allowed to the covert-way, for the planting of cannon; to oblige thofe who advance in the approaches to retire.

Thofe places of arms that are in the covered way, are places made at the entering and faliant angles, confiderably larger than the ftreet of the covered way, and formed by turning the head of the glacis into two faces, projecting towards the country: thofe at the faliant angles are formed by the rounding of the counterfcarp; thofe at the entering angles are conftructed by taking the gorges at the head of the glacis of a certain length, drawing the faces at a certain angle, and parallel to thofe faces drawing a glacis.

PLACE *of Arms*, in a camp, is properly the bell-tents at the head of each company, where the arms are lodged. It alfo denotes a large fpace at the head of the camp, for the army to be ranged in and drawn up in battalia.

PLACE *of Arms* of a troop or company, is the fpot of ground on which the troop, or company, draws up.

PLACE, *Face of a.* See FACE.

PLACE, *Tenaille of the.* See TENAILLE.

PLACE, *View of a.* See VIEW.

PLACE, *Fire.* See FIRE-PLACES.

PLACE, among logicians and orators, denotes the feat or fource of an argument; or that from which it is taken.

PLACE is ufed in the doctrine of artificial memory: and thefe places may be either fuch in a proper fenfe, as a door, a window, a corner, &c. or familiar and known perfons; or any thing at pleafure, provided that they be placed in a certain order, animals, plants, words, letters, characters, hiftorical perfonages, &c. though fome of thefe are more and fome lefs fit for the purpofe; but fuch kinds of places greatly help the memory, and raife it far above its natural power. See MEMORY and MNEMONICS.

PLACE, *Common.* See COMMON *Place.*

PLACE *of Units, Tens, &c.* See UNIT and NUMERATION.

PLACES, *Hylegial*, in *Aftrology.* See HYLEGIAL.

PLACE, *Whifpering.* See WHISPERING.

PLACE, *Additions of.* See ADDITION.

PLACE, *Unity of.* See UNITY.

PLACE *Bricks*, were kiln-burnt red bricks of a full fize, now entirely difufed in the metropolis; but in lieu of them, the foft infufficiently burnt bricks from the outfide of the clamps are called, by way of diftinction from ftock or hard burnt bricks, place bricks. Thefe are of a foul red colour, and will eafily break or crufh to pieces. The particular manner in which place bricks were formerly made was by dipping the mould in water before the clay was put in; which made the outer furfaces when burnt very coarfe and hard. See BRICK.

PLACENTA, in *Anatomy*, a vafcular fpongy body, containing the ramifications of veffels from the uterus, and of others from the fœtus, and forming the medium by which the mother and child are connected. See GENERATION.

PLACENTA, in *Natural Hiftory*, the name of one of the claffes of the echini marini. The characters of thefe are, that they are of a depreffed or flatted form, and are wrought in various fhapes, as the paftry people make their cakes; they all have a cinquefoil flower at their top, and their mouth is in the middle of the bafe; the aperture for their anus is ufually near the edge.

Of this clafs there are three genera: 1. The melitta. 2. The laganum. And 3. The rotula: which fee under their feveral heads.

PLACENTA, among the *Ancients*, a kind of cheefe-cake, the moft fimple kind of which was made of flour mixed with oil and cheefe, to which honey was added: but the more luxurious fort of people added likewife a great variety of herbs and fruits, as alfo fugar, eggs, butter, &c.

PLACENTIA, or PIACENZA, in *Geography*, a city of Italy, and capital of a duchy annexed to Parma, on the S. fide of the Po. This city was built and colonized by the Romans about 218 years B.C., and not long after, ferved as an afylum to the Roman army, when defeated by Hannibal at the Trebia. It was afterwards affaulted by that Carthaginian general, without fuccefs. This city became very flourifhing and municipal, but it fuffered much in the troubles that attended the elevation of Otho to the empire; and when attacked by a party of the Vitellians, it effectually refifted, and in the bloody conteft had only to lament the lofs of its amphitheatre, remarkable for its capacioufnefs and architecture, which was fet on fire and reduced to afhes. Placentia, after having frequently changed mafters, was annexed to Parma, and thus remained till the expulfion of the late duke, when, with the whole of its territory, it was occupied by the French. It is a large and well built city. Its cathedral is Saxon; the town-houfe, with fome other public buildings in the great fquare, Gothic. Several churches, particularly that of St. Agoftino, are of fine Roman architecture, and fome of them adorned with paintings of great celebrity. The great fquare is ornamented with two brafs equeftrian ftatues, one of Alexander Farnefe, and the other of his brother Ranuccio, which are much admired, particularly the former, for attitude, animation, and drapery. The ftreets of Placentia are handfome, broad, and ftraight: one in particular, called the Stradone, is reckoned the longeft and moft beautiful in Italy, being 3000 feet in length. Placentia is a bifhop's fee, and contains, befides the cathedral, 1 collegiate, 12 parochial, and 38 other churches, 8 abbies, 16 convents, and an univerfity. The number of inhabitants is about 20,000, including 2000 ecclefiaftics. The neighbourhood of Placentia is, perhaps, more interefting than the town itfelf, as it was the theatre of many bloody engagements. The duchy is about thirty miles long from N. to S., and from 8 to 15 broad from E. to W.; the foil is fertile, and furnifhes mines of iron, copper, and vitriol; 52 miles S.E. of Milan. N. lat. 45° 3′. E. long. 0° 43′.

PLACENTIA *Bay*, a fpacious bay on the S. coaft of Newfoundland, which forms a good harbour for fhips, and is frequented by fhips employed in the cod-fifhery, and by thofe that are bound into the gulf or river St. Lawrence. It opens between Chapeau Rouge Point W. and cape St. Mary's on the E., $15\frac{1}{2}$ leagues apart; lying between N. lat. 46° 43′ 30″ and 47° 54′, and between W. long. 54° 1′ and 55° 21′ 30″. The poft-town, which gives name to the bay, is on the eaftern fhore; 67 leagues to the E. of the ifland of Cape Breton, 40 miles W. by S. of St. John's, in N. lat. 47° 15′ and W. long. 55° 13′. The harbour is fo capacious, that 150 fail of fhips may lie in fecurity, and fifh as quietly as in any river. The entrance into it is by a narrow channel, which will admit but one fhip at a time. Sixty fail of fhips can conveniently dry their fifh on the Great Strand, which lies between two fteep hills, and is about three miles long.

long. One of the hills is ſeparated from the ſtrand by a ſmall brook, which runs out of the channel, and forms a ſort of lake, called the Little Bay, in which are caught great quantities of ſalmon. The inhabitants dry their fiſh on what is called Little Strand. The French had formerly a fort called St. Louis, ſituated on a ridge of dangerous rocks, which contracts the entrance into the harbour. In going in the ridge muſt be left on the ſtarboard.

PLACENTIA *Lagoon*, a bay on the coaſt of Yucatan. N. lat. 18° 38′. W. long. 89° 40′.

PLACENTIA *Iſland*, an iſland near the coaſt of Maine. N. lat. 44° 10′. W. long. 68° 10′.

PLACER *de Abraxas*, a rocky iſlet, near the S. coaſt of Cuba. N. lat. 21° 18′. W. long. 80° 52′.

PLACETTE, JOHN DE LA, in *Biography*, an eminent French miniſter and moraliſt, was born at Pontac, in Bearn, in the year 1639. He received the early part of his education under his father, who was miniſter of his native place; and after he had made good proficiency in the claſſics and the belles-lettres, he applied to the ſtudies requiſite to qualify him for the profeſſion of a divine. His firſt ſettlement was with the church of Orthès in Bearn; from which he removed, in about four years, to that of Nay, in the ſame province. Here he continued till the year 1685, when the revocation of the edict of Nantes compelled him to renounce his country for an aſylum among ſtrangers. He now gladly accepted an offer made him by the queen of Denmark, to become paſtor of a French church, which ſhe had founded at Copenhagen. He enjoyed the favour and patronage of that illuſtrious princeſs till her death, in 1711, when he removed into Holland. Here he firſt reſided at the Hague, and afterwards at Utrecht, where he died in 1718, in the 80th year of his age. His works are very numerous, of which ſome of the chief are as follow: "New Moral Eſſays," in 6 vols. 12mo.; "A Treatiſe on Conſcience," which was tranſlated into Engliſh by Baſil Kennet, under the title of "The Chriſtian Caſuiſt;" "A Treatiſe on Oaths;" "A Treatiſe on the Games of Chance;" and "A Compendium of Chriſtian Morality," of which the beſt edition is ſaid to be that of 1701. The character of this writer is thus drawn: "His knowledge was extenſive, his penetration lively, and his judgment calm and diſpaſſionate. His diſpoſition was benevolent, his manners affable, and his charity was extended to Chriſtians of all communions. With great clearneſs of perception, and ſoundneſs of judgment, he has very happily diſentangled and elucidated the moſt intricate and embarraſſed queſtions. Leſs profound than Nicole, and leſs ingenious than Rochefaucault, he will pleaſe good men by his ſolid morality, equally removed from exceſſive rigour and criminal remiſſneſs." His ſtyle, as a writer, is ſimple and equable, though frequently diffuſe. Moreri.

PLACIA, in *Ancient Geography*, a town of Aſia Minor, in Myſia, on the borders of the Propontide, between Panormus to the W., and the mouth of the Rhyndacus to the E. According to Pomponius Mela, and alſo Herodotus, this town was colonized by the Pelaſgi. Cybele was held in great veneration in this place, and as Cyzicus was very near it, the Cyzicanians worſhipped her under the name of the "Mother Placia."

PLACIDE, in *Biography*, a French monk, celebrated as an able geographer, was, probably, born at Paris in the year 1648. He was nearly related to, and pupil of, Peter Duval; and, at the age of 18, embraced the religious life in the convent of the Auguſtinian bare-footed friars, at the Place des Victoires. Here he appears to have made geography the principal purſuit of his life, and drew ſeveral maps and charts that were highly eſteemed, of which the moſt celebrated is that of "The Courſe of the River Po," conſiſting of ſeveral ſheets. On account of his great ſkill and ingenuity in this branch of ſcience, he was, in 1705, appointed geographer in ordinary to the king. He died in 1734, at the advanced age of 86. An engraved likeneſs of this able man is ſometimes to be met with as a frontiſpiece to collections of his maps. But the monks of his fraternity obtained poſſeſſion of the plate, and deſtroyed it, out of reſentment to Placide, who refuſed to ſubmit to their newly adopted faſhion of being ſhaved; and he is repreſented in the engraving as wearing a beard. Moreri.

PLACIDIA, a Roman empreſs, the daughter of Theodoſius the Great, by his ſecond wife Galla. She was born about A.D. 388, and was brought up in the palace of Conſtantinople. When her brother Honorius was ſeated upon the throne of the weſtern empire, ſhe took up her reſidence in Rome, and was in that capital when it was inveſted by Alaric in 408. At the third ſiege and ſack of Rome in 410, Placidia was one of the captives whom the conqueror carried away with him; ſhe was, however, treated with the reſpect due to her rank and ſex. After the death of Alaric, Ataulphus, who ſucceeded him as king of the Goths, refuſed to reſtore her, and at length made propoſals of marriage to her. She ſubmitted, ſays Gibbon, without reluctance to the deſires of the conqueror, a young and valiant prince, who yielded to Alaric in loftineſs of ſtature, but who excelled him in the more attractive qualities of grace and beauty. The marriage of Ataulphus and Placidia was conſummated before the Goths retired from Italy. The bride, attired and adorned like a Roman empreſs, was placed on a throne of ſtate, and the king of the Goths, who aſſumed on this occaſion the Roman habit, contented himſelf with a leſs honourable ſeat by her ſide. The nuptial gift, which, according to the cuſtom of the nation, was offered to Placidia, conſiſted of the rare and magnificent ſpoils of her country. Fifty beautiful youths, in ſilken robes, carried a baſin in each hand, and one of theſe baſins was filled with pieces of gold, the others with precious ſtones of ineſtimable value. Theſe, however, formed an inconſiderable portion of the Gothic treaſures. She brought forth a ſon, who ſoon died, and ſhortly after, in 415, Ataulphus was murdered by one of his domeſtics in Spain. Singeric, who uſurped the Gothic throne, treated Placidia with great ignominy, and obliged her to walk twelve miles before his chariot with a crowd of other captives; but Singeric was aſſaſſinated a few days after his elevation. By a treaty between the Romans and Goths, ſhe was afterwards ranſomed at an immenſe price, and returned to Italy. In 417, her brother Honorius, as a reward for the ſervices of his general Conſtantius, compelled her to give him her hand in marriage. She manifeſted great reluctance to this union, which, nevertheleſs, was productive of a ſon and daughter, named Valentinian and Honoria. Placidia again became a widow in 421, after her huſband had occupied the throne only ſeven months. After this Placidia ſought for herſelf and children a retreat at Conſtantinople, where ſhe was honourably received by her nephew Theodoſius, who granted to Placidia the title of Auguſta, and to her ſon that of Cæſar. In 425, Placidia again recovered her authority, and aſſumed the reins of government, as regent, during the minority of her ſon. Her adminiſtration was not remarkable for wiſdom or vigour, and ſhe has been charged with the deſpicable and criminal policy of corrupting her ſon by a diſſolute education, that ſhe might the longer keep the power in her own hands. At any rate, ſhe ſeems to have governed with abſolute ſway till her death, at the age of 62, in the year 450. She was interred at Ravenna, where her tomb, and even her corpfe feated in a cyprefs chair, were preferved for many ages. This emprefs received many compliments from the orthodox clergy, and St. Peter Chryfologus affured her, that her zeal for the Trinity had been recompenfed by an auguft trinity of children. Univer. Hift. Gibbon, vols. v. and vi.

PLACITA, PLEAS, a term frequent in our laws and cuftoms. Originally, placita fignified certain public affemblies of all degrees of men, in which the king prefided, and where the great affairs of the kingdom were confulted upon.

Thefe affemblies were called *placita generalia;* becaufe *generalitas univerforum majorum tam clericorum quam laicorum ibidem conveniebat.* And hence the decrees, ordinances, fentences, &c. of this affembly, were alfo called *placita.*

Sim. Dunelmenfis tells us, they were held in the open fields; for, fays he, *nullam oportet regem in literis affignare curiam, quia ubi rex judicat in aperto ibi eft curia fua.*

Some will have thefe *placita generalia,* and *curiæ regis,* of ancient times, to be much the fame with what we now call a *parliament.*

The lords courts came hence alfo to be called *placita generalia,* though oftener *curiæ generales;* becaufe all their tenants and vaffals were obliged to appear in them.

We alfo meet with *placitum nominatum,* for the day appointed a criminal to appear in, and make his defence. Leg. Hen. I. And *placitum fractum, i. e.* when the day is lapfed.

Lord Coke derives the word *placitum à placendo, quia beneplacitare fuper omnia placet:* indeed, this feems a very fanciful etymon; and others have more reafon in deriving the word from the German *platz,* or the Latin *plateis, fields,* or *ftreets,* where thefe affemblies were originally held.

PLACITARE, in the old *Law Books,* fignifies to plead caufes. See PLEADING.

"Mos placitandi, ante Conquæftum, fuit coram aldermanno, et proceribus, et eorum hundredariis, fc. barônibus, majoribus, melioribus, fenioribus, et urbanis." Mifc. in Bibl. Cott. fub. tit. Vitellius.

Hence, *placitator, a pleader.* Ralph Flambard is recorded to have been *totius regni placitator,* in William II.'s time.

PLACITUM, in *Law,* a fentence of the court; or an opinion, ordinance, or decree.

Cuftos PLACITORUM *coronæ.* See CUSTOS.

PLACKET, or PLAQUETTE, in *Commerce,* a fmall filver coin of the Netherlands, of $3\frac{1}{2}$ ftivers current. The old plaquettes have been reduced to $2\frac{1}{2}$ ftivers. The affay of the placket is W. (worfe than the Englifh ftandard) 5 oz. 8 dwt.; its weight, 1 dwt. 18 gr.; its contents in pure filver grains, 20: and its value in fterling, 0*s.* $2\frac{3}{4}$*d.*

PLACODIUM, in *Botany,* from πλακωδης, *broad and cruftaceous,* a divifion of the natural order of *Lichenes,* as firft diftributed by Hoffmann, and conftituting the fourth fection of his feventh genus, *Lobaria.* It compofes the fecond tribe in the *Prodromus* of Acharius, but has no part in the fubfequent arrangement, publifhed in his *Methodus.* See LICHENES.

PLACUS, from πλακους, *a cake,* becaufe the inhabitants of Cochinchina ufe the fragrant juice of the genus in queftion, as an ingredient in cakes.—Lour. Cochinch. 496.—Clafs and order, *Syngenefia Polygamia-fuperflua.* Nat. Ord. *Compofitæ nucamentaceæ,* Linn. *Corymbiferæ,* Juff.

Gen. Ch. Common calyx imbricated, inverfely turbinate, fcales linear, flender, erect. *Cor.* compound, equal to the calyx, erect; *florets* of the difk few, all perfect, tubular, five-cleft; thofe of the circumference very numerous, naked. *Stam.* (in the perfect florets) Filaments five, very fhort; anthers forming a cylindrical tube. *Pift.* (in all the florets) Germen oblong; ftyle thread-fhaped, fhort; ftigmas two, oblong, erect in the perfect florets, reflexed in the female ones. *Peric.* none, except the unchanged calyx. *Seed* to each of the florets oblong, moft flender in the female ones; down capillary. *Recept.* naked, convex.

Eff. Ch. Receptacle naked. Down capillary. Calyx imbricated, inverfely turbinate, with linear fcales. Florets of the radius without a corolla.

1. P. *tomentofus.* Lour. n. 1.—Leaves ovate, obtufe, downy on both fides. —Found wild, as well as cultivated, in Cochinchina. *Stem* herbaceous, two feet high, erect, branched. *Leaves* alternate, feffile, ferrated, odoriferous. *Flowers* violet, in terminal, erect, oblong panicles.

2. P. *lævis.* Lour. n. 2.—Leaves ovate, pointed, fmooth. Native of the fame country.—*Stem* not quite fo tall, fmooth. *Flowers* pale yellow, in fhort terminal panicles. *Calyx* tumid at the bafe. We know nothing of thefe plants but from the account of Loureiro. See ELICHRYSUM, GNAPHALIUM, and ERIGERON.

PLADAROTIS, from πλαδαρος, *fluid,* in *Surgery,* a fungous tubercle upon the infide of the eye-lid.

PLADIA, or BLADIA, in *Geography,* a town of Pruffia, in the province of Natangen; 22 miles S.W. of Konigfberg.

PLADLING, a town of Bavaria, fituated on the Ifer; 8 miles N.W. of Ofterhofen.

PLAFOND, or PLATFOND, in *Architecture,* the ceiling of a room, whether it be flat or arched; lined with laths and plafter, and fometimes alfo enriched with paintings, &c. See CEILING.

PLAFOND is alfo more particularly ufed for the bottom of the projecture of the larmier of the corniche; called alfo the foffit.

PLAGALIS, Lat. πλαγιος, *obliquus, à latere.* Plagal and authentic, in the ecclefiaftical modes, or canto fermo, imply the different divifions of the octave: the divifion is called *authentic,* when the 5th is in the acute; and *plagal,* when the 4th is in the grave. (See PLAIN CHANT, and MODES, *Ecclefiaftical.*) The terms *authentic* and *plagal* are with reafon cenfured by Meibomius and Bontempi as barbarous. Bontempi propofes, inftead of the word *authentic,* to fubftitute *principal;* and for *plagal, relative* or *collateral.* Thefe diftinctions in the Romifh church are fimilar to the difcriminations made by the Greek mufical writers where they clafs their modes under the denominations of *principal* and *fubordinate,* with the diftinction of *hyper* and *hypo.* It is not furprifing that the primitive Chriftians fhould give Greek names to the fpecies of octaves in imitation of the Greek modes; nor, if we reflect on the fimplicity that was aimed at, and the humble ftate of thofe who firft employed mufic in their religious worfhip, fhall we wonder at the incorrect and artlefs manner in which it was done. How the Roman church acquired Greek terms in canto fermo it is eafy likewife to imagine, if we recollect that it was a prefent from Greek fathers: and Gregory, in reforming the mafs, not only retained thefe Greek terms, but adopted others, both from the Greek and Hebrew languages and ceremonies, in order to conciliate parties, and acquire converts: as *Kyrie Eleïfon* from the Greek, and *Hallelujah* from the Hebrew.

PLAGIANTHUS, in *Botany,* fo called by Forfter, from πλαγιος, *oblique,* and ανθος, *a flower,* becaufe of the oblique difpofition of the petals, which gives the flower an irregular

irregular appearance.—Forſt. Gen. t. 43. Schreb. 459. Willd. Sp. Pl. v. 3. 719. Mart. Mill. Dict. v. 3. Juſſ. 274.—Claſs and order, *Monadelphia Dodecandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſimple, of one leaf, inferior, bell-ſhaped, with five ſmall acute ſegments. *Cor.* Petals five, obovate, rounded, with claws, two of them folding over each other, at a diſtance from the reſt. *Stam.* Filaments united into a cylinder, the length of the petals; anthers about twelve, ovate, crowded about the top of the cylinder. *Piſt.* Germen ſuperior, ovate, very ſmall; ſtyle thread-ſhaped, concealed within the tube of the ſtamens; ſtigma club-ſhaped. *Peric.* Berry . . . . *Seeds* . . . .

Eſſ. Ch. Calyx ſimple, five-cleft. Petals five; two of them together, remote from the reſt. Style one. Stigma club-ſhaped. Berry . . . .

1. P. *divaricatus*. Forſt. Prodr. 47. Willd. n. 1.—Found by Forſter in New Zealand.—A *ſhrub*, with alternate, ſmooth, ſlender *branches*, clothed with a ſmooth, ſhining, purpliſh-brown bark. *Buds* alternate, of two or three brown membranous ſcales. *Leaves* three or four from each bud, linear, ſomewhat obovate, bluntiſh, with a little point, entire, ſmooth, about half an inch long, tapering at the baſe, but ſcarcely ſtalked. *Flowers* ſolitary, adjoining to the leaf-buds, whitiſh, each on a recurved ſmooth *ſtalk*, not half the length of the leaves. We have, like Willdenow, merely ſeen one of Forſter's dried ſpecimens. Nothing can bear much leſs reſemblance to a malvaceous plant, except that the inner bark ſeems fibrous. Willdenow moſt truly remarks that this genus has nothing in common with *Connarus*, to which it ſeems, by a manuſcript note of the younger Linnæus, ſome great botaniſts had referred it.

PLAGIARA, or PLAGIARIA, in *Ancient Geography*, a town of Spain, in Luſitania, upon the route from Oliſipo to Emerita, between Emerita and Budua, according to the Itinerary of Antonine.

PLAGIARY, in *Philology*, *Author-theft*; or the practice of purloining other people's works, and putting them off for a man's own.

Among the Romans, *plagiarius* was properly a perſon who bought, ſold, or retained a freeman for a ſlave; ſo called, becauſe the Flavian law condemned ſuch a perſon *ad plagas*, to be whipped.

Thomaſius has an expreſs treatiſe *de plagio literario;* wherein he lays down the laws and meaſures of the right which authors have to one another's writings. Dictionary writers, at leaſt ſuch as meddle with arts and ſciences, ſeem in this caſe to be exempted from the common laws of *meum* and *tuum;* they do not pretend to ſet up on their own bottom, nor to treat the reader at their own coſt. Their works are ſuppoſed, in great meaſure, compoſitions of other people; and whatever they take from others, they do it avowedly. In effect, their quality gives them a title to appropriate every thing that may be for their purpoſe, wherever they find it, and they do no otherwiſe, than as the bee does, for the public ſervice.

Their occupation is not pillaging, but collecting contributions; and, if you aſk them their authority, they will produce you the practice of their predeceſſors of all ages and nations.

PLAGIAULUS, Πλαγιαυλος, among the *Ancients*, a kind of flute.

PLAGIOPLATEUS, in *Natural Hiſtory*, a term uſed by Artedi and others, to ſignify depreſſed, in oppoſition to the term cathetoplateus, which ſignifies compreſſed.

PLAGIUM, in *Civil Law*, the offence of ſpiriting away and ſtealing men and children: whence the offenders were called plagiarii, and were puniſhable with death. See KIDNAPPING.

PLAGIURI, in *Natural Hiſtory*, the name of one of the great claſſes, or families of fiſh: the characters of which are, that the tail is placed horizontally; they reſpire by means of lungs, and have uſually a double fiſtule in the head; they are viviparous, and the males have a penis and teſtes, the females the vulva, ovaria, mammæ, &c. and they bring up their young with milk.

The term is derived from the Greek πλαγιος, *tranſverſe*, and ουρα, *a tail.*

Under this claſs of fiſh are comprehended the following genera: the phyſeter, delphinus, balæna, monodon, catodon, and trichechus; which ſee under their reſpective articles.

PLAGUE, λοιμος, *Peſtis*, in *Medicine*, called alſo *peſtilence*, *peſtilentia*, *peſtilitas*, a term which has been applied to various epidemic and fatal diſeaſes, but is now limited by phyſicians to a contagious and malignant fever, which is accompanied by buboes and carbuncles.

Some correſponding appellation is to be found in all languages by which an extenſive and deſtructive malady of this kind is deſignated. There is little doubt, however, that theſe raging epidemics have conſiſted of different maladies in different inſtances; having been ſometimes the remittent fever originating from marſh effluvia, ſometimes the true plague, and ſometimes perhaps the ſmall-pox, or ſcarlet fever; occaſionally, too, even the *ignis ſacer*, or epidemic land-ſcurvy, the reſult of a dearth of nutriment, appears to have been denominated peſtilence. (See IGNIS *Sacer*.) In many inſtances, the plagues deſcribed by hiſtorians are only depicted by the extent of the mortality and miſery which they carried with them, and their peculiar ſymptoms are not detailed; ſo that it is impoſſible to aſcertain the nature of the malady itſelf. And in ſome caſes, though the phenomena of the diſeaſe are partially deſcribed, yet the general deſcription is obſcure and doubtful. Such is the character of the ſtriking hiſtory of the plague at Athens, which has been left by Thucydides: it ſeems to be ſufficiently diſtinct to prove that that epidemic was not the true plague; ſince the glandular ſwellings were not among the ſymptoms. The deſcription of the ſtate of the ſkin, indeed, impreſſes the notion of ſmall-pox, rather than of any other contagious diſeaſe; for it is ſaid to have been "reddiſh or livid, with an eruption of *ſmall puſtules and ſores.*" (φλυκταίναις μικραῖς καὶ ἕλκεσιν ἐξηνθηκος. Thucyd. lib. ii. § 49.) But ſome of the ſymptoms apparently belong to the *ignis ſacer*. Lucretius has given a poetical tranſlation of this hiſtory of the plague, as detailed by Thucydides. (Lib. vi.) Some of the plagues mentioned by Livy, as occurring among the Romans, do not appear to have been accompanied by the glandular tumours and carbuncles of the true plague.

In more modern times, the various forms of peſtilence have been ſomewhat more accurately diſtinguiſhed; and during the fifteenth, ſixteenth, and ſeventeenth centuries, various countries both of Europe and Aſia have been afflicted with the viſitations of the true plague; ſo that its form and character have been but too well recognized. We ſhall endeavour to collect into one view the various appearances which it exhibits.

The noſological definition of the plague given by Dr. Cullen, is "a typhus fever, in the higheſt degree contagious, and accompanied with extreme debility. On an uncertain day of the diſeaſe there is an eruption of buboes or carbuncles." (Noſol. Method. Gen. 30.) On the whole, this

this brief character of the difeafe is as correct as any that can be given; for, in fact, the difeafe varies greatly in its appearances in different inftances; infomuch that even fever is by no means invariably prefent; and in the more fatal cafes of plague, death terminates its courfe, before a fufficient time has elapfed to admit of the formation of buboes and carbuncles.

It is not eafy to give a general hiftory of the fymptoms of the plague; becaufe, in its different degrees of violence, its courfe and character exhibit very material variations. Hence it has been the practice of almoft all the phyficians, who have publifhed their obfervations on the difeafe, to divide the congeries of fymptoms into feveral claffes: the phyficians of Marfeilles defcribed five fpecies of the malady, and Dr. Ruffell divided it into fix; while Lange, Orræus, and others, fpeak only of three types which it affumed, or three degrees of violence, the mild, fevere, and malignant.

The general derangement of the fyftem, which ufhers in an attack of the plague, is much like that which commences the courfe of ordinary fever. A fenfe of cold, with fome fhivering, which is foon followed by heat, and acceleration of the pulfe, with giddinefs, head-ache, depreffion of ftrength and fpirits, white tongue, vomiting, or diarrhœa, and great oppreffion about the præcordia, are among the firft fymptoms of the difeafe. Thefe are fucceeded by a burning pain about the pit of the ftomach, by a peculiar muddinefs of the eyes, by coma, delirium, and other affections of the fenforium, which terminate by death in fome cafes on the fecond or third day, before the pathognomonic fymptoms, buboes, and carbuncles, have appeared; but which, in others, continue to increafe, while thefe morbid changes enfue, together with purple fpots and ecchymofes, which belong to the plague, in common with other malignant fevers. Without attempting a defcription of the different claffes of the plague as fubdivided by the writers above-mentioned, we fhall follow the laborious Dr. Ruffell through fome of his remarks on the particular fymptoms, as he obferved the difeafe at Aleppo.

The fever is prefent at one ftage or other of the plague with very few exceptions, though it differs materially in its degree, duration, and fymptoms, in different individuals. It is ufually preceded by a wearinefs and a confufion of head, which becomes a fevere pain as the fever advances. The cold ftage is fhort, and lefs marked than in an intermittent; but the changes in the fucceeding hot fit are fudden, anomalous, and alarming. Naufea and vomiting frequently occur from the beginning; but thefe fymptoms are abfent in a large proportion, even in cafes which terminate fatally. Indeed in many the attack is fcarcely to be diftinguifhed from that of ordinary fevers before the fecond night, unlefs where buboes and carbuncles arife within the firft twenty-four hours. Although thefe remove all doubts about the nature of the fever, they do not, however, afford any certain prognofis of the event of the difeafe. In fome cafes clear remiffions occur on the fecond or third day; but in general the changes from better to worfe are frequent in the courfe of the firft twenty-four hours, and more fudden and various than in common fevers. The difeafe in moft cafes advances with extreme rapidity, infomuch that the patient on the fecond or third day is often in point of debility, diforder of the fenfes, and of the vital functions, reduced apparently to the condition of one in the laft ftage of a malignant fever; yet to this defperate ftate will fucceed a remiffion, in which his fenfes and intellectual faculties are reftored, and weaknefs only feems to remain. Neverthelefs, thefe remiffions, when occurring early in the difeafe, or when not preceded by a fweat, are often fhort and fallacious: but when they follow a perfpiration on the third day or later, and are of fome hours continuance, they afford hopes of a favourable iffue.

Delirium in the plague feldom becomes fo violent and phrenitic, as in fome other fevers. It fometimes comes on the firft night, but in general not before the fecond; and is higheft in the febrile exacerbations. Sometimes delirium alternates with coma, which laft is in general a more dangerous fymptom, but moft particularly fo when it comes on early, and does not abate in the remiffions.

The change in the *eyes*, which has been defcribed as a *muddinefs*, is extremely remarkable. It fometimes takes place on the firft day, but more commonly on the fecond or third, and remains till fome favourable turn of the difeafe occurs. "It refembled fomewhat the dull fixed eye obfervable in the laft ftages of malignant fevers, but the dullnefs was different, muddinefs and luftre being ftrangely blended together:" and Dr. Ruffell adds, that it contributed much to that confufion of countenance, which enabled him, after a little experience, to pronounce with tolerable certainty on the exiftence or nonexiftence of the plague. The *tongue* very often retains its natural appearance; and where it change its colour, it becomes only white, and remains moift, feldom becoming parched, and never putting on fo thick a fur, or affuming fo dark a colour, as in the advanced ftages of fome other fevers. The *pulfe* is generally low, quick, and equal; and in the latter ftages it becomes exceedingly quick and fmall, efpecially during the exacerbations, fo as to be fcarcely perceptible; yet in fome cafes, when the difeafe is confiderably protracted, and other fymptoms denote much diforder, the pulfe varies little from its natural ftate. In fact, the variations of the pulfe are often quite incongruous with the other fymptoms. The refpiration is little difordered, except in the advanced ftage: there is no fœtor of the breath, nor cough; but there is an extreme anxiety and oppreffion about the præcordia, which produce great inquietude, and where they come on early, always dangerous fymptoms. They are often accompanied by a pain and diftreffing fenfe of heat in the epigaftrium, probably connected with the ftomach, and rather increafed than relieved by the vomiting.

The functions of the brain and nerves are particularly affected by the attack of the plague; fo that a fudden and extreme proftration of ftrength belongs to the difeafe under all circumftances, and is, in fact, the moft marked characteriftic of its fevere and fatal forms; the vital principle appearing to be fuddenly as it were extinguifhed, or fo enfeebled at once as to be incapable of refifting the violence of the diforder.

Vomiting did not occur in a very large proportion of the fick at Aleppo: but where it appeared at the beginning, and continued with fhort intervals, it generally denoted a fatal termination. The matter ejected from the ftomach was various at the beginning, it was only the ordinary contents of the vifcus; but after repeated reachings, bile commonly followed. Dr. Ruffell did not obferve any fetid difcharges from the ftomach; but a blackifh liquor fometimes came off in the laft ftage of the difeafe. A diarrhœa began fometimes on the firft day, but more commonly in the advance of the complaint, and was generally confidered as a dangerous fymptom; but the ftools were lefs offenfive than thofe in tertian fevers in the fame climate. Sometimes dark coloured blood was difcharged by ftool unmixed with fæces, and without griping pains. As a loofenefs of the bowels was generally detrimental; fo, on the other hand, a ftate of of coſtiveneſs was attended with no harm or inconvenience.

But the peculiar and characteriſtic ſymptoms of the plague, as before ſtated, are the *buboes* and *carbuncles*, the former being obſerved in almoſt all thoſe patients who are not carried off too rapidly to admit of their formation. The carbuncles, however, do not occur in more than one-third of the caſes of plague, and very rarely exiſt alone, being generally conjoined with buboes. Buboes occur in the glands of the groin and arm-pits, and alſo in the parotid, maxillary, and cervical glands; but thoſe of the groin are moſt frequently affected.

The inguinal peſtilential bubo ſometimes appears in the ſame place as the ordinary venereal tumour, but is commonly ſituated lower in the thigh. A burning and ſhooting pain is often felt in the part before any ſwelling is perceptible by the finger; but when once diſtinguiſhable, the gland is always painful on preſſure. In the incipient ſtate of the bubo, a ſmall, hard, round tumour is felt under the finger, moveable under the ſkin, ſoft, and of its natural colour; but as the ſwelling increaſes, it aſſumes more of an oblong form, becomes leſs moveable, and the integuments become thickened and tumid. In ſome caſes the ſwelling is acutely painful, in others obtuſely ſo, and its progreſs is not leſs variable. The ſkin is ſeldom inflamed in any degree during the firſt week, though tenſe and painful; ſo that in the fatal caſes, it generally retains the natural colour; indeed, unequivocal ſigns of the tendency to ſuppuration ſeldom occur till the fever abates, and is manifeſtly on the decline, as about the eighth or ninth day; the external inflammation then advances, the ſwelling becomes ſofter, and breaks between the fifteenth and twenty-ſecond day, when treated ſimply with poultices. Thoſe buboes which do not terminate in ſuppuration, uſually diſperſe gradually, and diſappear altogether in the ſecond month: ſome of the inguinal tumours, however, remain hard and indolent for a longer time.

In a very large proportion of thoſe who are attacked by the plague, the buboes begin to appear on the firſt day of the diſeaſe; ſometimes they are even the very firſt ſymptom of infection; and ſometimes they do not ariſe until the third day, or even later. Sometimes there is a ſucceſſion of two or three buboes in the ſame patient.

The *anthrax*, or *carbuncle*, which is not unfrequently conjoined with the bubo, appears under ſome variety of form. Dr. Ruſſell has deſcribed five, Dr. Gotwald (who ſaw the plague at Dantzic) four, and others three varieties of this peſtilential ſore. In different inſtances, it commences in the form of an inflamed puſtule, of various ſize and colour, or of an angry pimple, tubercle, or ſlightly elevated red or livid ſpot; and inſtead of ſuppurating kindly, it becomes black, and forms a gangrenous eſchar, ſurrounded by an inflamed and tumid margin. The part is affected with a pricking and burning pain. Dr. Bancroft obſerves, that when carbuncles appear very early, they aſſume a dark brown or black colour, and remain forty-eight hours or more without being circumſcribed by an inflamed margin: they generally indicate the greateſt danger. Moſt commonly, however, they appear only in the advanced ſtages; and where ſeveral occur in the ſame ſubject, they generally appear in quick ſucceſſion. They are ſeated in different inſtances, on every external part of the body, even on the ſcrotum, and on the eye-brows; and when they concur with buboes, they uſually appear on the ſame ſide of the body: ſometimes, however, the carbuncles and buboes appear on the oppoſite ſides. Sympathetic buboes occaſionally ariſe in conſequence of carbuncles; but they are leſs intenſely painful than primary buboes, and diſperſe when the carbuncles ſuppurate kindly.

Some other eruptive appearances occur during the plague, which are among the ſymptoms of all malignant fevers: theſe are eſpecially *petechiæ* and *vibices*, or purple dots and blotches; ſome of them reſembling in ſize and appearance the marks of flea-bites, and ſome the ſtripes and bruiſes of a whip. In ſome caſes, a ſort of marbled appearance of the ſkin takes place, or the ſurface is diſcoloured by narrow ſtreaks of a brown, purpliſh, red, or livid colour. Moſt of theſe appearances, which are obviouſly of a petechial nature, were vulgarly called *tokens* in the plagues of London; being conſidered, and not unjuſtly, as commonly betokening the approach of death. Some of theſe indeed ſeem, from the deſcription given by Dr. Hodges, to have been elevated, as if blood had been effuſed under the cuticle. "The *tokens*," he ſays, "were of various ſizes, ſometimes as ſmall as a pin's head, ſometimes larger, and as broad as a ſilver penny. Some were depreſſed, others prominent. They differed alſo in their degrees of hardneſs, ſome being eaſily penetrable by a needle or a pen-knife, &c. They were not all of the ſame colour, but often bore ſo ſtrong a reſemblance to warts, that they were often miſtaken for them, not only by the vulgar, but even by the ſurgeons; and the author himſelf was ſometimes obliged to have recourſe to the needle for diſtinguiſhing them. A quick ſenſibility was a good ſign, and thoſe which went no farther than the ſkin would often ſlough off; whereas when they went deeper, they were deemed dangerous, eſpecially when the part loſt its feeling, and threatened ſphacelation." (Hodges, Loimologia, p. 133.) The ſame excellent author deſcribes another peſtilential eruption; thoſe of this kind were popularly called *blains*, and were a ſort of blebs or *bullæ*, containing ichor or ſerum. Theſe, he ſays, were "veſications of ſize from a pea to a nutmeg, encompaſſed with a variegated circle, generally reddiſh. They aroſe with exquiſite and ſhooting pain, and contained an ichor of a yellowiſh or ſtraw colour, which was ſo acrid or cauſtic, that it ſoon corroded the veſicle, and burſt out, of a colour yellowiſh, livid, or black. Theſe puſtules broke out in many parts of the body, their ſtation and number being uncertain; ſometimes few, ſometimes many: in one caſe, the whole body was covered all over with them." (Loc. cit. p. 110.) In the directions publiſhed by the College of Phyſicians for the ſearchers, the latter are ordered to examine "whether there be any blains which may riſe in any part of the body in form of a bliſter, much bigger than the ſmall-pox, of a ſtraw colour or livid colour, which latter is the worſer; either of them hath a reddiſh circuit, ſomething ſwollen, round about it; which circuit remains after the bliſter is broken, encompaſſing the ſore." See Certain neceſſary Directions, by the King's ſpecial Command, Lond. 1665.

Such are the ſymptoms which characterize the formidable malady, the plague. In different caſes, they are of courſe variouſly combined, and aſſume various degrees of violence, according to the age, ſtrength, and conſtitution of the patient. They differ alſo materially according to the ſeaſon, and to the particular period of the epidemic; inſomuch that the proportion of fatal caſes, among thoſe who are attacked at different periods of its prevalence, varies greatly. But the fatality of the diſeaſe is greater in general than that of any other malignant fever, and cuts off the majority of thoſe whom it ſeizes, from two to ſeven days from its attack. All ages and conditions, every variety of conſtitution, ſtrong and feeble, and both ſexes under every circumſtance, are liable to the infection; which, during thoſe particular ſeaſons in which it has become epidemic, has therefore

 committed

committed the moſt dreadful deſtruction in the population of thoſe towns and diſtricts, which it has unhappily viſited.

It may ſeem extraordinary that the origin of a diſeaſe, which has in all ages been the ſcourge of mankind, ſhould have been always the ſubject of doubt, or at leaſt of much difference of opinion. It is, however, to this day diſputed, whether the plague be propagated by contagion or not; and it muſt be admitted that there are ſome difficulties attending either ſuppoſition. A ſimilar diſcuſſion, indeed, has been carried on, with ſome acrimony, reſpecting the epidemics of our own times, eſpecially reſpecting the yellow fever of the Weſt Indies and America; and ſome even diſputed the nature of the fever, which ſpread ſo extenſively and fatally among our troops in the recent expedition to Walcheren. The moſt intelligent writers, however, concur in aſcribing epidemic diſeaſes to two ſources; namely, to the miaſmata or effluvia of marſhes, and to contagion, or the exhalations and ſecreted matter from the bodies of perſons diſeaſed. To the former ſource, marſh effluvia, the intermittent and remittent fevers, which are endemic in particular diſtricts at certain ſeaſons of the year, and often extenſively prevalent and fatal, are generally aſcribed; and they are diſtinctly traceable to certain combinations of heat and humidity acting upon vegetable and animal ſoils. (See Epidemic.) Hence in the autumnal ſeaſon, flat, marſhy countries, the ſeat of camps and other large congregations of men, and the uncleanly parts of crowded cities, have generally been obſerved to be productive of intermittent and remittent fevers. (See Health *of London.*) Now ſome of theſe circumſtances alſo concur in favouring the propagation, if not in giving origin to the plague; whence the difficulty of admitting the contagious ſource of the latter has ariſen. It has alſo been ſtated, as an objection to the opinion that the plague is propagated by contagion, that, in many places, the diſeaſe is ſeldom entirely abſent; yet that it rages epidemically and fatally only at particular times. Thus, it is collected from the bills of mortality of London, that, although there were but four great plague-years in this metropolis during the ſeventeenth century, namely, the years 1603, 1625, 1636, and 1665, (in the two firſt of which about 35,000, and in the laſt 68,000 died,) yet that there were but three years, from the commencement of the bills of mortality in 1603 until 1670, which were entirely free from the plague. In many of theſe intermediate years, indeed, the mortality of the diſeaſe was very conſiderable: for the bills exhibit 900 deaths by the plague, in 1604; 400, in 1605; 2000, in 1606; the ſame in the two following years; and even ſo late as from 1640 to 1648, the number every year exceeded 1000. (See Dr. Heberden's Treatiſe on the Increaſe and Decreaſe of different Diſeaſes, p. 75.) Diemerbroeck remarks, in his excellent Treatiſe on the Plague, that whenever the plague has been excited out of its proper ſeaſon, it has not ſpread; and it has been obſerved by Dr. Ruſſell, that, in winter time, when infected perſons have come to places about Aleppo, ſome of whom have died of the diſeaſe in the families where they lodged, the diſtemper was not by ſuch means propagated. Dr. Hodges has alſo ſtated, in a ſtrong point of view, the total freedom from infection experienced by thoſe perſons, who had fled from London during the ravages of the plague, in the autumn of 1665, when they returned in the winter to the houſes and beds in which their friends had died of the malady, without any previous purification having been made of the very linen and clothes which they had uſed. See his Loimologia.

It is likewiſe an indubitable fact, that the plague has always firſt appeared and eſtabliſhed its head-quarters in the filthieſt parts of crowded, ill-conſtructed, and large cities, and has committed its moſt fatal ravages among the loweſt of the people. Thus at Grand Cairo and Conſtantinople it appears almoſt annually. Blackmore takes notice that the impurity and filth, connected with the galleys and ſlaves at Marſeilles, filled the air with offenſive ſmells, eaſily perceivable by thoſe that paſſed along the adjoining ſhore; and in 1720 the plague broke out there, in a part of the town thronged by the pooreſt people. In London, Dr. Heberden obſerves, the plagues of 1626 and 1636 broke out at Whitechapel, a part of the town which abounded with poor and with ſlaughter-houſes: that of 1665 is ſaid to have broken out firſt at St. Giles's; and there it would probably break out again, if ever we ſhould ſuffer ſuch another calamity. Hodges affirms, that in 1665 the diſeaſe was ſo much more prevalent among the lower claſſes, that it acquired the appellation of the *poor's plague.*

All theſe facts, however, when taken into conſideration, along with the more poſitive evidence in favour of the actual contagion of the plague, perhaps tend only to prove that the human body is more prediſpoſed to be acted upon by the contagion, under certain circumſtances, which materially influence the ſtate of the conſtitution. It muſt be admitted, indeed, as a matter of daily obſervation, that a certain prediſpoſition of the body is requiſite for the production of all diſeaſes, and for the operation of contagion in particular: otherwiſe it could not happen that great numbers ſhould eſcape during the whole reign of an epidemic; that at different ſeaſons of the year, one and the ſame cauſe (a chill, for inſtance, or an act of intemperance) ſhould produce very different diſeaſes, a catarrh, a cholera, or a bilious fever. A particular ſtate of the air is, in fact, abſolutely neceſſary for the propagation of the contagion of the plague; for it is only during a ſeaſon of moderate heat that it has ever been obſerved to prevail extenſively. In Europe it has invariably raged moſt violently and fatally in the ſummer and autumnal months, eſpecially in September. Thus in the plague of London in 1665, the deaths from the plague were, in June, 590; in July, 4129; in Auguſt, 20,046; in September, 26,230; in October, 14,373; in November, 3449; and in December, they were under 1000. (See the Bills of Mortality.) The cold weather of northern climates has invariably been obſerved to check the ravages of the plague. On the contrary, however, the extreme heat of ſouthern latitudes is equally adverſe to the propagation of the contagion; ſo that the diſeaſe is, in fact, unknown in tropical climates. In Egypt and Syria, its progreſs is always ſuſpended during the hotteſt months of the year. (See Ruſſell on the Plague, and Bancroft on Yellow Fever, p. 579.) "But a proper ſtate of the air," to uſe the words of Dr. Heberden, "is not the only circumſtance neceſſary to promote the operation of contagion. During the epidemical conſtitution, it is highly probable that good diet, and good ſpirits, and cleanlineſs, and freſh air, and proper clothing, and exerciſe, may all contribute to render the body leſs ſuſceptible of diſeaſe; the ſeeds of which, like thoſe of vegetables, will then only ſpring up and thrive, when they fall upon a ſoil convenient for their growth." (On the Increaſe and Decreaſe of different Diſeaſes, p. 68.) Theſe obſervations are corroborated by the fact, univerſally obſerved during the prevalence of the plague, that the principal ravages are committed upon the lower claſſes of the people; and they are perhaps farther confirmed, by the frequent occurrence of peſtilence in combination with dearth and famine, according to the general teſtimony of hiſtorians, during which the people are not only ill-fed, but ill ſupplied with

with fuel, clothing, and other healthful accommodations, and alfo difpirited in the extreme.

Dr. Bancroft has collected fome facts and teftimonies which concur in pointing out the circumftances which induce a predifpofition in the body to receive the contagion of the plague, or to refift its influence. He quotes Dr. Pugnet's opinion, that the fufceptibility of a perfon for the contagion is greatly increafed by a moderately warm and moift atmofphere; that children, females, and perfons of delicate feeble conftitutions, are moft apt to become infected; and that thofe who are naturally robuft and vigorous feldom take the difeafe, unlefs weakened by exceffive fatigue, watching, exceffive venereal indulgence, or intoxication. Dr. Defgenettes remarks, that the plague feemed more particularly to attack thofe who are expofed to fudden tranfitions from a hot to a cold atmofphere, and *vice verfâ*, fuch as bakers, cooks, and blackfmiths; and that men addicted to exceffes with women and fpirituous liquors, very feldom recovered from the difeafe.

Dr. Bancroft has alfo adduced fome obfervations, made by himfelf, in proof of the influence of atmofpheric heat and cold, in both their extremes, in rendering the contagion dormant, or in fufpending that fufceptibility or affinity of the human body, without which it cannot produce difeafe in ordinary circumftances. Peftilential contagion, he obferves, probably exifts at all times in Lower Egypt, Syria, and many of the great cities of the Levant, and it is frequent on board Turkifh and Greek veffels. When he was in Egypt, he remarked, that the obvious effect of heat in leffening the fufceptibilities of individuals, or their aptitudes for taking the difeafe, was moft evident in thofe who had lately arrived from cold climates, and who were comparatively moft affected by the fummer's heat; and afcribed his own efcape, at that time, to that circumftance. "There were, however, perfons in Egypt," he adds, "who had been long accuftomed to greater degrees of heat, and who were therefore not rendered infufceptible of the difeafe, and fome few of thefe caught it after it had become extinct in the Britifh army, and when a perfon landed from England would not receive it, though he flept in an infected bed; and it was from this caufe, that in the autumn of the fame year, the difeafe began at Rofetta nearly two months before the ufual time, *i. e.* on the 13th of September, when I firft difcovered it in two natives of the Eaft Indies, attached to the Indian army; and it was propagated with fome rapidity for fix or eight weeks, among perfons who were either born in, or had juft come from, a climate *much hotter* than Egypt, whilft the Britifh troops directly from England did not receive, and probably could not have been made to take the difeafe." On Yellow Fever, p. 591.

It is fortunate for mankind, as the fame able author has remarked, that the communication of the contagion of the plague depends upon the co-operation of fo many favourable circumftances, and particularly upon that of a fuitable temperature, and of certain aptitudes and fufceptibilities in the human fubject; for without fuch requifites, or fuch obftacles to its propagation, the earth might have long fince become defolate.

It would feem fuperfluous to enter into a long detail of facts to prove that the plague is a *contagious* difeafe, notwithftanding the refufal of fome perfons to admit the fact. The majority of the hiftories of the plague teem with evidences from which it is undeniably inferred. It is more efpecially to be inferred, however, from the circumftance of the multitude of medical attendants on the fick under this malady who have perifhed by its attacks, and particularly of thofe who have been under the neceffity of the moft clofe contact with the infected. Dr. Samoilowitz, who for many years officiated as an army furgeon in places where he had numerous opportunities of feeing perfons under the plague, and efpecially during that of Mofcow in 1771, has filled nearly one hundred pages of his treatife "fur la pefte," with proofs of its contagious influence; and among thefe he mentions, that having fucceffively volunteered his fervices as chief furgeon, in three of the principal hofpitals of Mofcow, *all* the affiftant furgeons who were employed under him, fifteen in number, took the difeafe, which terminated fatally in eleven of them. The medical officers of the French army, during their campaign in Egypt, experienced the effects of the contagion to a great extent; about *eighty* of them perifhed by the plague within one year, according to Dr. Sotira, who was one of the furvivors. He adds, that in the two following years, it was thought expedient to employ Turkifh barbers to drefs buboes, carbuncles, and blifters, as well as to bleed, and apply frictions of oil, under the infpection of French phyficians and furgeons, and that, in confequence of this arrangement, only twelve medical officers died in twice the former time. He alfo ftates, that more than half of the Turks, who were thus employed to affift the French furgeons, took the plague, which, in feveral inftances, proved mortal; though among a confiderable number of other Turks, employed at Rofetta by the French *to bury the dead*, only one caught the difeafe. This is one of the many facts which indicate that there is comparatively little danger in handling the bodies of infected perfons *after death*, than while alive. See Bancroft, loc. cit. and Gaetan Sotira, Mem. fur la Pefte, obfervée en Egypt, p. 5.

The plague, which ravaged Marfeilles in 1720, appears to have afforded ample evidence of its contagious nature. The report tranfmitted to the regent by M. Chicoyneau on the 18th of Auguft, reprefents the phyficians and furgeons as unanimous in their declaration, "that when one perfon in a family was attacked and died, the reft foon underwent the fame fate, infomuch that there were inftances of families entirely deftroyed in that manner; and if any one of an infected family fled to another houfe, the contagion accompanied him, and proved fatal to the family where he had taken refuge." (Relation Hiftorique, p. 115.) It appears, too, from the hiftorical record juft quoted, that the firft hofpital opened for the infected proved fatal to all the attendants. The introduction of the plague into the Hôtel Dieu was traced to a woman received as a patient from the rue de l'Efcale, the ftreet in which the diftemper firft broke out. Two of the nurfes who affifted at her reception, and the matron who changed her linen, were taken ill the next day, and died after a few hours' illnefs. In confequence of the dreadful rapidity with which the contagion fpread in that eftablifhment, it deftroyed phyficians, furgeons, apothecaries, confeffors, and all the other officers and fervants, with the whole of the poor in the hofpital, including above three hundred foundlings. The priefts and monks who attended the infected fuffered in the fame manner as the medical affiftants. And, laftly, of two hundred and thirty galley-flaves, employed in going into the infected houfes, and burying the dead, two hundred and twenty perifhed in the fpace of ten or twelve days. The whole tenour of the hiftory of that plague, indeed, concurs to eftablifh the fact of its contagious nature. We fhall, therefore, conclude this brief detail with the obfervations of Dr. Ruffell, fuggefted by his experience in the Eaft.

"If of one hundred perfons, expofed to the infection of of the plague by a near approach to the fick, ninety fhould fall ill, fhall human inability to affign fatisfactory reafons for the prefervation of the other ten, be converted into a pofitive argument againft the difeafe having been caught by contagion? If perfons retired from all commerce with the infected and their attendants, breathing the fame air with the reft of the inhabitants, and nourifhed by the fame aliment, remain untouched during the ravage of the plague, as long as they continue fecluded, but upon unguarded communication are taken ill like others,—can any rational doubt arife about the caufe of their former fecurity? Or if through ftealth, or neglect of requifite precautions, fubftances tainted by the fick fhould be conveyed into thefe fecluded retreats; and perfons living temperately as before, ignorant of what had happened, and confequently in the midft of imaginary fecurity, happen to be feized with the diftemper,—can it with any fhow of reafon be afcribed, not to contagion, but to terror, or to colluvies in the ftomach and bowels, produced by intemperance and bad aliment? The inftances here alluded to are not the creation of fancy, but ftrictly confonant to repeated experience in Turkey; to fay nothing at prefent of what has been obferved at Marfeilles, and in various cities in Europe." Ruffell on the Plague, p. 208.

We cannot, therefore, but confider the *contagious* nature of the plague as fatisfactorily proved, though not demonftrable. The principal difficulty in the way of an unqualified admiffion of the propofition, is the complete and often fpeedy eradication of the difeafe in a place, where no particular means of purification have been employed, by which the contagion might be removed or deftroyed. But this difficulty is not infurmountable, as we have already attempted to fhew, and as might be farther illuftrated by a reference to the progrefs of thofe contagious difeafes, which admit of no difpute, fuch as the fmall-pox and meafles. For even thefe are only widely epidemic and feverely fatal at particular feafons, when circumftances, that are not always cognizable, give a peculiar virulence to the contagion, or a predifpofition to the human conftitution to receive its influence.

The contagion of the plague, like that of the common malignant fever, or typhus, of temperate climates, and unlike that of fmall-pox, may infect a perfon a fecond time. Dr. Bancroft fays, "two cafes of *re-infection*, or fecond attacks of plague, fell under my obfervation in Egypt; one occurred in Mr. Webfter, then an affiftant furgeon, and the other in a foldier of the 27th regiment, each of whom had a bubo: they were, however, but flightly indifpofed, the weather having become hot. Dr. Buchan had a fecond attack, but with only a fmall carbuncle, as he informed me. Dr. Price alfo had a fecond attack, without either bubo or carbuncle, but, according to his account, with a violent affection of the head and nervous fyftem." In general," he adds, "I think fecond attacks are milder than the firft, though Dr. Price informed me of his having feen a lad, who, under fuch an attack, died on the fecond day. Pugnet fays, that re-infections, when they occurred, were ofteneft in perfons who had been mildly treated by the firft attack; and that feveral of thefe had the difeafe very violently the fecond time, immediately after ufing the bed or blanket of perfons who had died of it." (Loc. cit. p. 599.) The fact of the occurrence of the plague in the fame individual more than once, is, indeed, fully eftablifhed upon the beft authorities, although fome have difputed it. Merteus fays of the plague at Mofcow, "Experientia comprobatum fit, hanc (peftem) illos non folum in variis vitæ periodis, fed et eadem epidemia, bis, aut fæpius occupare poffe." (Obf. Med. p. 123.) Dr. Ruffell alfo bears teftimony to the fame fact in the epidemics which he witneffed at Aleppo. Neverthelefs, a fecond infection is admitted to be rather a rare occurrence, at leaft during the fame epidemic. In above one hundred and twenty peftilential cafes recorded by Diemerbroeck, there are only two in which the patients had been infected twice during the fame feafon; but he had met with feveral inftances of perfons attacked at Nimeguen, who had fuffered the plague fome years before. (See Diemerbroeck De Pefte, lib. iv. Hift. 37, and 45.) Whether the obfervation of Thucydides is thus fanctioned, as applicable to the true plague, may be queftioned. He fays that, in the plague of Athens, "thofe who recovered had much compaffion on thofe who were dying, and thofe who lay fick, as having known the mifery themfelves, and *were now in a fecure condition, for it never feized the fame perfon twice fo as to be fatal.*" (Thucyd. de Bello Pelopon. lib. ii.) As the fymptoms defcribed by Thucydides were more analogous to thofe of the fmall-pox than of the true plague, as above ftated; fo this confidence of the convalefcents in their fecurity (which is not ufual in cafes of the true plague when epidemic) rather confirms the opinion the plague of Athens was fmall-pox.

With refpect to the *treatment of the plague*, very little that is fatisfactory can be collected from the writings of thofe who have witneffed its ravages. Dr. Bancroft expreffes an opinion, that, until we know more of the ways and means by which nature endeavours to overcome it, we can perhaps do but little for her affiftance, except by reftraining all violent and dangerous fymptoms, all exceffive and debilitating evacuations, and fupporting, when neceffary, the powers of life, by a moderate ufe of wine, ether, opium, volatile alkali, and Peruvian bark. "The inftances of perfons who have ftrangely recovered from the plague, after having wandered alone about the country, particularly in Egypt, expofed to *cold* and *wet*, feem to indicate, that even the moft moderate fweating is at beft ufelefs; but on the other hand, the unfuccefsful trials made by Dr. Price, of the cold bath, afford no encouragement to repeat fuch applications to the furface. In fome few cafes, where the difeafe occurs in the vigorous and robuft, and is accompanied with highly inflammatory fymptoms, bleeding might perhaps prove beneficial, if employed within a few hours from the attack; though in general very bad effects appear to have refulted from this evacuation. Mild emetics are faid, in fome cafes, to have proved beneficial, given at the very beginning of the difeafe."

This paragraph feems to contain the fum of the information, which is to be found in the records of modern medicine on the fubject. *Blood-letting*, in general, is to be deprecated in a difeafe, in which the inflammatory fymptoms are feldom confiderable, and the depreffion of ftrength ufually great and fudden. And in like manner, all violent evacuations, either by *emetics* or *purgatives*, appear to be detrimental, efpecially as violent vomiting and diarrhœa are apt to occur fpontaneoufly, and are deemed very unfavourable fymptoms. Dr. Ruffell remarks, that "the neglect of purging at the beginning was not followed by the confequences which might rationally have been expected," and, he adds, "I never faw any acute diftemper, where coftivenefs was attended with fo little inconveniency. Neverthelefs, I think it rational, by gentle means, to clear the bowels at the beginning from any colluvies that might happen to be lodged there; for though that did not conftantly prevent loofenefs, or other fymptoms produced by matter pent up, and rendered more putrefcent by the fever, yet I think it fometimes had that effect; and the paffage of the bowels often appeared

peared to relieve the head, both in the augment and decline of the difeafe."

It appears to have been a very early and general opinion, as Dr. Bancroft remarks, among the phyficians of this and other neighbouring countries, that thofe who were attacked with the plague, and other contagious difeafes, had imbibed a *morbid poifon*, and that it was neceffary, above all things, to affift nature in expelling that poifon from the body, and this principally by *fweating*, which Morton called the king's highway. In "certain rules, directions, or advertifements, for this time of peftilential contagion, firft publifhed for the behoofe of the city of London, in the vifitation of 1603," and republifhed upon the recurrence of the plague in 1625, *copious fweatings* were directed to be excited by ftrong fudorifics, with warm beds and bed-clothes, "fo foon as any of them (the poorer fort of people) apprehend themfelves to be taken with the plague," and thefe were to be repeated every eight hours, and they were to "continue this courfe for four or five days;" and while they were fweating, it was ordered that they were not to be fuffered "to reft or fleep." The fame modes of treatment were adopted in the "advice fet downe by the College of Phyficians, by his majefties fpeciall command," which was printed in 1630. Not only ftrong fudorifics were enjoined, but it was directed "that there be good fires kept in and about the *vifited* houfes, and their neighbours," and "to make fires rather in pannes, to remove about the chambers, than in chimneys, the better to correct the ayre of the houfes." In 1665, the College of Phyficians were required by government to infpect the rules of former times, and make fuch alterations as they deemed proper; and among the directions which they then publifhed, after mentioning bleeding, purging, and vomiting, they fay "thefe three great remedies rarely have place in the plague, but are generally dangerous, and moft of all purging, by any ftrong medicines," but exprefs an opinion, that "the poifon is beft expelled by fweating, provoked by *poffet-ale*, and *London treacle*" mixed; and order the patient to "be put to bed to fweat, well covered in a blanket, without his fhirt, for twenty-four hours, every fifth hour renewing his cordial, but in half the quantity, between whiles refrefhing him with poffet drink, oatmeal caudle, or thin broths, made jelly, wine, or hartfhorn jelly;" and, if neceffary, warm bricks, wetted with vinegar, and wrapped in flannel, were to be put to his feet, and care was to be taken, that he "fleep not till the fweat be over." *Bliflers* were at the fame time to be applied "behind the ears, about the wrifts, near the arm-pits, on the infides of the thighs, and near the groin, to *draw forth the venom*. The buboes were to be "always drawn forth, and ripened, and broke with all fpeed."

Such was the univerfal practice employed in the plagues of the feventeenth century; and it is enough to have ftated it to prove the mifchievous confequences which it muft have produced, to the fatisfaction of every pathologift of the prefent day. The miliary fevers, of which the writers of thofe times fpeak fo much, were the actual product of this violent excitement (fee MILIARIA); and the fmall-pox was rendered doubly fatal by the fame treatment. That coolnefs of the bed and apartment, with the moft liberal admiffion of air, and the moft complete reft that can be obtained, fhould be enforced under every form of fever, is now demonftrated beyond the poffibility of difpute. And it is not lefs clearly afcertained, with refpect to the management of the buboes, or glandular fwellings, that, although it may be proper to promote their fuppuration by emollient cataplafms, &c., where a natural difpofition to that iffue is evident; yet that there can be no danger or impropriety in favouring their difperfion or refolution, by the ufual means, when a fpontaneous tendency to fuch a termination is obferved. Dr. Bancroft juftly fays, "I know that the fudden retroceffion of buboes, previous to fuppuration, and whilft other fymptoms indicating danger fubfift unabated, is often followed by death. But this mortality is not in fuch cafes produced by any change in the bubo itfelf, or by the retention of any matter which ought to be difcharged, but by fuch an extreme diminution of the living power, or other injurious effects of the difeafe, as is incompatible with the continuation of a fuppurating procefs, and alfo with the patient's recovery; and, therefore, this retroceffion is to be confidered not as the caufe of death, but as an indication and confequence of that condition of the patient, from which death neceffarily refulted; and on the other hand, when thefe glandular fwellings rife, and fuppurate favourably, they indicate fuch a ftate of the living power and of the fyftem, as is likely to overcome the difeafe, without the fuppofed benefit of an evacuation of morbid poifon by that fuppuration. The fame reafoning appears applicable to carbuncles, though in their gangrenous ftate, and when not furrounded by concentric inflamed rings, they require hot ftimulant applications, and afterwards fuch as will promote a fuppuration, and a feparation of the carbonaceous cruft." On Yellow Fever, &c. p. 617.

It may be added, that *mercurial* preparations were employed, and pufhed as far as they could be carried, during the plague at Marfeilles (according to M. Deidier) without any good effect. Orræus, Pugnet, and Sotira, likewife give their teftimony to the fame refult of their own experience, even when carried to falivation. But where the difeafe is violent, it is obvious that fufficient time cannot be given to affect the falivary glands, even if the advantage of doing fo were clear; and when they have been affected, it is probable that this was rather the effect, than the caufe, of the mild and protracted ftate of the difeafe.

Frictions with oil were ftrongly recommended by Mr. Baldwin for the cure of the plague; but the evidence in favour of their efficacy is very defective. Thefe frictions, Dr. Bancroft informs us, were tried extenfively by the French phyficians in Egypt, and with very little, if any benefit, though in a few cafes they feemed to give temporary eafe. Puguet indeed fays, that they were not only ufelefs, but caufed anxiety and difturbance to the fick; that of fifteen patients to whom thefe frictions were applied, under the French phyfician Carrie, one recovered with difficulty, and all the reft died; and that where they feemed to do good, the difeafe was always mild. With fo much reafon to doubt of their efficacy, there is a ftrong objection to their ufe, arifing from the very great danger of communicating the difeafe to the unfortunate perfon by whofe *hands* they may be applied, and thus deftroying many lives, without much probability of faving one. Bancroft, p. 623.

Prevention of the Plague.—The meafures to be adopted for the prevention of the propagation of the plague are directed to two objects; namely, to the prevention of the introduction of the contagion into any town or country from thofe places where it prevails; and to the prevention of its propagation among the population, if it have already been introduced.

It feems to be generally admitted, that the plague does not originate in this country; and, therefore, from its infular fituation, the infection can only be introduced through the medium of fhips. Egypt, the Levant, and other parts of the Mediterranean, are feldom entirely free from the malady in the cool and temperate feafons; and probably, therefore, never free from the lurking contagion which the

 congenial

congenial temperature annually brings into action. It is chiefly, therefore, through the medium of the commerce of the Mediterranean, that the importation of the contagion is to be apprehended; and to guard againſt this danger, the ſyſtem of *quarantine* is adopted by the government of this country. It will not be neceſſary here to enter into a full detail of this ſyſtem in all its parts, as it will be deſcribed under its proper head. (See QUARANTINE.) The objects of the ſyſtem are, in the firſt place, to detain the individuals who may poſſibly have the infection lurking about them, a ſufficient length of time from any communication with the people on ſhore, in order to aſcertain whether the diſeaſe ſhall make its appearance in them; but, in the next place, to perform a ſtill more important ſervice, by ſubjecting all goods, clothes, and merchandize, which may retain infection, to a proceſs of purification. It is well known, not only from numerous facts recorded in the hiſtory of almoſt all modern plagues, but from the teſtimony of the moſt experienced phyſicians in reſpect to malignant fevers in general, that theſe *fomites*, as they are called, or ſubſtances imbued with the contagion from the bodies of the ſick, may retain their infectious quality an indefinite length of time, and do in fact more readily communicate the diſeaſe, than the perſons of the infected. In addition, therefore, to the mere delay of the quarantine, the purification of the goods contained in the ſhips makes a principal part of that ſyſtem; and it is chiefly accompliſhed by the eſtabliſhment of lazarettoes and peſt-houſes, at the principal ports to which veſſels from the Mediterranean uſually come. The perſons, if any prove to have been infected, and ſhew ſymptoms of the plague, are immediately removed to theſe houſes, and ſeparated from the healthy; and the goods are there alſo opened out, and expoſed to the air, and fumigated with ſulphureous vapours, and thoſe of the mineral acids. (See FUMIGATION.) The moſt rigid adherence to the principle of ſeparation, eſtabliſhed by the quarantine laws, is enforced by the ſtatutes, and the ſyſtem appears to have anſwered the purpoſe of preventing the importation of peſtilential contagion, ſince it has been fully practiſed.

If, however, theſe meaſures ſhould fail to prevent the introduction of the plague into any large town, it then becomes expedient to deviſe the beſt means of preventing the ſpreading of the contagion among the people. This, indeed, is an object of difficult attainment. The firſt riſe and appearance of the plague is not always recognized, and therefore it has often made conſiderable progreſs before any public meaſures are called for. The great rule of reſiſting in the beginning ("principiis obſta") is of peculiar importance in ſuch a caſe; and it is much to be lamented, as Dr. Mead has remarked, that, in addition to this phyſical difficulty in the execution of the rule, the very ſteps which have commonly been taken by the police, with the view of arreſting the contagion, have unfortunately had a direct tendency to impede the operation of this maxim, and to accelerate the progreſs of the epidemic. Dr. Mead juſtly ſtates, that the directions of the magiſtrate, under ſuch circumſtances, ought to be ſuch as to encourage the families firſt infected to make their misfortune known, for the ſake of obtaining aſſiſtance, as much as if their houſe were on fire; whereas the meaſures uſually adopted on theſe occaſions have, in fact, been themſelves a ſevere puniſhment, and muſt have contributed to make the infected conceal the diſeaſe as long as poſſible.

When the plague firſt ſhewed itſelf in London in 1665, the orders iſſued by the lord mayor and aldermen, and ſanctioned by the College of Phyſicians, principally related to the ſtrict impriſonment of the ſick in their own houſes, by watchmen attending night and day at the doors to prevent communication; and this was to continue at leaſt a month after all the family was dead or recovered. Each infected houſe was ordered "to be marked with a red croſs of a foot long, in the middle of the door, evident to be ſeen, and with theſe uſual printed words, that is to ſay, *Lord have mercy upon us*, to be ſet cloſe over the ſame croſs, there to continue until lawful opening of the ſame houſe." (See Orders by the Lord Mayor and Aldermen, concerning the Infection of the Plague, 1665.) Independently of the miſery thus ſuffered by the families ſhut up, when comfort and aſſiſtance from friends is moſt required, and ſtrangers to every thing but the melancholy view of the progreſs which death makes among themſelves, the inefficacy of the plan to prevent the ſpread of contagion is obvious. The contagion muſt be accumulated and rendered more virulent by ſuch confinement; "the ſhutting up houſes in this manner," as Dr. Mead obſerves, "is only keeping ſo many ſeminaries of contagion, ſooner or later to be diſperſed abroad; for the waiting a month or longer from the death of the laſt patient, will avail no more than keeping a bale of infected goods unpacked; the poiſon will fly out, whenever the Pandora's box is opened." (Mead on the Plague, p. ii. chap. 2.) This plan, too, excited the univerſal apprehenſions of the people, leſt they ſhould be ſhut up, which, probably, like all other impreſſions of fear, increaſed their liability to the infection. It occaſioned the concealment of the diſeaſe as long as poſſible, which neceſſarily contributed to give it vigour, and to ſpread it; nor was it poſſible to maintain it rigidly; for many broke out of their confinement, by getting out at the windows, &c. or by bribing the watchmen at their doors, and ſometimes by aſſaulting them; and thus contributed to propagate the contagion. On the other hand, there are ſome ſtrong proofs recorded in the plagues of London in 1625 and 1636, of the diminution of the mortality which occurred after the ſick houſes were permitted to be open. See Mead, loc. cit.

On the actual occurrence, or on the apprehenſion of the occurrence, of the plague in any place, a council of health ſhould immediately be appointed, conſiſting of ſome of the principal officers of ſtate, ſome of the magiſtrates, and two or three phyſicians, &c.; and this council ſhould be entruſted with ſuch powers, as might enable them to enforce the execution of their orders with impartial juſtice, avoiding all unneceſſary hardſhips. Inſtead of ignorant old women, who have generally been appointed *ſearchers* in pariſhes to examine the cauſes of death, that office ſhould be committed to intelligent and active men, whoſe buſineſs it ſhould be to report to the council of health the firſt occurrence of extraordinary deaths in any diſtrict, ſo that the ſuſpected bodies ſhould be examined by ſkilful phyſicians. The plague having almoſt invariably appeared among the poor in the outſet, the meaſures to be adopted are principally applicable to that claſs of people. If, upon the report of the examiners and phyſicians, the plague is actually aſcertained to have occurred, the families ſhould be immediately removed, the ſick and the ſound to different receptacles out of town, in which every care ſhould be taken to purify the clothes and perſons of both, on admiſſion. The wealthy might be compelled to remove to their country houſes, following a ſimilar plan of ſeparation and purification. From what is now known reſpecting the nature of contagion, it is certain that if theſe lazarettoes were kept in a cleanly and well-ventilated ſtate, like the houſes of recovery for typhus, there would be much leſs danger in giving attendance upon the ſick, and the chance of recovery would be much augmented. It is well aſcertained by experiment, that contagion is very much weakened

weakened in its virulence by dilution with fresh air, and that, in this diluted state, it may be breathed for a certain time with impunity. See CONTAGION, and HOUSE *of Recovery*.

There are many examples of the success with which these plans of early separation of the infected have been pursued. The magistrates of the city of Ferrara, in the year 1630, when all the surrounding country was infected with the plague, observing the ill consequences which every where ensued from endeavours to conceal the disease, by keeping the sick in their houses, resolved, whenever the occasion should occur, to adopt a different method. Accordingly as soon as they were informed that a person had died of the plague in their city, they immediately removed the whole family to which he belonged into a lazaretto, where they all, seven in number, died. But though the disease was thus malignant, it went no farther, being suppressed at once by this method. Within the space of a year, the same circumstance recurred seven or eight times, and the same proceeding put a stop to its progress. The example of this city was afterwards followed more than once in some other towns in the same territory, and with such complete success, that it was thought expedient, for the common good, to publish in the Memoirs of the people of Ferrara this declaration; "that the only remedy against the plague is to make the most early discovery of its occurrence that is possible, and thus to extinguish it in the very beginning." A very similar success was obtained by cardinal Gastaldi at Rome, in the plague of 1657. Being appointed commissary-general of health, with full powers, by the pope, he ordered all infected persons to be removed upon the first notice, to a lazaretto in the island of the Tiber, and all who lived in the same house with them, to other hospitals just without the city, in order to be sent to the island if they should fall sick. In two months he thus cleared the city of the plague, which had continued in it nearly two years; and it was particularly observed that, although previously, when the disease once got into a house, it seldom ceased without seizing the whole family, yet, under this management, scarcely five out of a hundred of the sound persons, thus removed, were infected. See Gastaldi, de avertenda Peste, cap. 10.

When the sick families are removed, their goods should be destroyed, or buried, and the walls and floors scoured, lime-washed, fumigated, and well aired. The streets and alleys should be cleansed with peculiar care, and washed daily if possible. It has generally been deemed advisable, too, to take up all beggars and vagrants who have no fixed residence, and may become a great cause for disseminating the contagion; and to prohibit all public amusements and assemblies of people, by which the disease might be communicated, through the promiscuous intercourse of such meetings.

Upon the supposition, (which is doubtless erroneous,) that the atmosphere is impregnated with contagion, or with some impurities which favour its propagation, the purification of the air has been an object of solicitude at all times, and *fire* has been recommended both by the ancients and moderns for this purpose. This opinion, however, seems to rest upon no better foundation, than a tradition that Hippocrates put a stop to a plague in Greece by kindling large fires; a circumstance which is no where mentioned in his works. It appears, indeed, that in after times these fires were made with juniper, cypress, resin, myrrh, and other aromatic weeds and gums, and that a sort of fumigation, and not the mere heat of fires, was the object of the practice. The experiment, when made in London, during the last plague, does not lead to any favourable inference respecting the operation of this practice; for Dr. Hodges has stated, that fires having been ordered in all the streets for three days together, there died in one night immediately following no less than four thousand persons; whereas in any single week before or after twice that number had never been carried off. (Loimologia, p. 24.) The same observation appears to be applicable to the firing of guns, which would likewise be productive of the additional evil of exciting constant alarm, and disturbing the sick.

It is certainly desirable that the population should be thinned as much as possible, at the first appearance of the plague, by the departure of as many people from the town into the country as can conveniently do so. Those who are under the necessity of remaining, should adopt as far as possible a system of seclusion; for, however improper it may be to shut in the contagion, where it has already appeared, it must obviously be prudent to *shut it out*. Hence many persons have effectually preserved themselves and their families, in those countries where the plague often prevails, by shutting themselves up, and avoiding all unnecessary communication with the public, before any of them had received the infection. In large houses, in which a full ventilation could be accomplished, the chance of escape under this system of exclusion would be great; and even if any person should be taken suddenly ill, an immediate separation from the rest of the family would probably preserve them from the contagion. Dr. Russell, during the plague at Aleppo, shut himself up in his house, and prescribed to numerous patients who were brought to his window, which was a few feet above the ground, and by this plan escaped the infection entirely.

In houses in which the disease has already appeared, cleanliness and a free admission of air are the best preservatives; indeed, the circumstance of the comparative rarity of the diseases among the higher classes of society can only be explained upon this principle. Constant washing or mopping the apartments of the sick also contribute materially, by the coolness produced, to benefit the sick. The fumigations with aromatic herbs and gums, employed on those occasions, are not of any effectual use, and the very odours which they emit, rather conceal the presence of offensive vapours, than contribute to destroy them. The fumigations with the mineral acid vapours, obtained by decomposing nitre or common sea-salt, are, however, possessed of the power of destroying contagion. (See FUMIGATION.) The same fumigations, therefore, should be applied to the linen, beds, furniture, &c., in preference to the mere smoking, or the use of aromatic fumes, which were recommended previously to the discovery of these more efficient methods. See an ample account of the ancient modes of fumigation in Dr. Russell's Treatise on the Plague, book vi. ch. 6. p. 561—8.

The next means of prevention to be considered, are those by which individuals may defend their persons against the prevalent contagion. These, however, lie within a much smaller compass than the public appear to suppose. There is certainly no direct antidote against the infection, which can be externally worn, or internally taken. It were superfluous to describe the ingredients of the little bags, balls, ointments, and amulets, employed as preventives of the disease; as they have no claims whatever to the title of antidotes, and are, for the most part, either the offspring of empirical craft, or mere innocent devices, to give confidence to those who are under the necessity of approaching the sick. In this last view, indeed, such as do no harm may be admitted, in compliance with popular notions; but where such reliance is placed in them as to remove more important caution, even these are to be deprecated.

As to the alleged internal prefervatives, with which the older medical books are copioufly ftored, they are in general compofed of a complex farrago of herbs and gums, of very queftionable properties of any kind. Thefe have been copied, with very little alteration, from the formulæ of dark and ignorant times, and confift of a few medicated ales, diftilled waters, and electuaries. It will be fufficient to mention one of thefe compofitions, calculated for the rich, which was preferved among the revifed directions of the College of Phyficians in 1665, and was difgraced by the following ingredients; oriental bezoar, pearl, hyacinth ftone, unicorn's horn, and lignum aloes, the proportion of the laft article being about three grains to four hundred and fifty of the other ingredients. In truth, unlefs individuals have a ftrong prepoffeffion in favour of thefe ufelefs expedients, and lofe all confidence without them, they may be fully difpenfed with. The principal fyftem of prevention that can be of any avail, muft confift in maintaining that ftate of health in which we are leaft liable to fuffer from the exciting caufes of difeafe. We muft neither weaken the body by evacuations, nor ftimulate and excite plethora by high living. A temperate and regular courfe of life, and a temperate ufe of cuftomary liquors, promife every advantage that can be expected from cordial and ftomachic medicines; inanition, long fafting, immoderate watching, late hours, heated rooms, cafual debauches, exceffive fatigues, fudden changes in diet, fhould be cautioufly avoided; inafmuch as whatever deftroys the balance of moderate health, induces a predifpofition to difeafe, under which contagion, like other occafional caufes of diforder, more readily operates upon the fyftem. Grief, terror, defpondence, and other debilitating affections of the mind, have been univerfally held to be of moft dangerous tendency in peftilential times; while, on the contrary, a regular flow of fpirits, cheerfulnefs, a temper not given to anticipate evils, and a lively hope of efcaping infection, are confidered as the beft fafeguards againft contagion. Thefe, however, it is not in the power of medicine altogether to beftow; but this confideration affords the only apology for the ufe of the inert amulets before mentioned. The ufe of *tobacco* was confidered by Diemerbroeck and others as conducive to repel the infection of the plague. But the experience of Dr. Ruffell led him to doubt the correctnefs of this opinion; as thofe who ufed tobacco copioufly did not appear to be lefs liable to the difeafe than others. At Aleppo, indeed, the cuftom of fmoking is univerfal both among men and women of all ranks, and therefore the very fact of the frequent prevalence of the plague feems to afford a refutation of this opinion. The beft prefervative is certainly to avoid a near approach to the fick, and efpecially to avoid the contact of the fick and of their clothes. The remarkable fact, mentioned by Dr. Samoilowitz, that all the affiftant furgeons in the hofpitals at Mofcow, took the plague, while the phyficians, who only walked among the fick, but carefully avoided contact, generally efcaped, affords a ftrong proof of the greater facility with which actual contact communicates the infection.

Moral Confequences of the Plague.—Having ftated every thing which appears to be material in the phyfical hiftory of the plague, we cannot altogether omit the confideration of fome of the moral evils, which have commonly been obferved in the train of every fevere peftilence. So urgent are the phyfical diftreffes which peftilence inflicts, and univerfal the interruption to the ordinary intercourfe of focial life which it occafions; fo neceffary is it for individual fafety to fhun all communication with others, and fo difficult, therefore, to obtain affiftance when in need of it; that a fyftem of felfifh principles becomes every where prevalent, and the ordinary moral rules of conduct are every where laid afide; and vices, follies, and crimes, of every defcription, contribute to augment the fum of mifery, which peftilence brings with it. The extreme uncertainty of the tenure of life, when every day may probably terminate it, feems to loofen the moral ties of the people, partly becaufe multitudes of thofe who are the arbiters of individual character are deftroyed, partly becaufe, in the general confufion, the chance of efcaping detection is much diminifhed, and partly becaufe the probability of living to undergo punifhment is exceedingly fmall. The extreme and fudden changes of fortune, too, which the death of whole families brings unexpectedly to many, unhinges the moral feelings, and leaves the indulgence of the paffions to be purfued with little controul.

A ftriking picture of the diffolution of morals, during the prevalence of the peftilence at Athens, has been drawn by Thucydides. After ftating that, in confequence of the dreadful mortality, the people, not knowing what to do, or whither to go, began to neglect all their duties facred and profane, he firft obferves, that the rites of burial were not performed at all, from the deftruction of fervants and domeftics, or performed in the moft irregular manner. Some, he fays, would take poffeffion of the funeral piles erected by others, and anticipating their arrival, would lay the bodies of their friends upon them, and fet them on fire; while others would depofit their corpfe upon the burning pile containing one already partly confumed, and retire. "But this malady," he proceeds, "was the fource of much greater depravities to the city in other refpects. For people now dared to do many things openly, which they were heretofore compelled by fhame to conceal; and they calculated upon their fudden change of fortune, feeing that many of the wealthy perifhed, while thofe who formerly were deftitute, became rich with their property. They, therefore, deemed it right to fet about the immediate enjoyment of it, and gave up all mind to pleafures, confidering that they in turn might be deprived of the treafures, and of life itfelf in a few days. Nor was any individual difpofed to undertake any labours for an honourable reward, becaufe he thought it uncertain whether he fhould not die before he could obtain it. Whatever each perfon deemed agreeable or lucrative to himfelf, this he confidered as expedient and honourable; and he did not allow himfelf to be reftrained in the purfuit of it, either by the fear of God or of human laws. This indifference to all moral and religious duties, arofe partly from the circumftance, that the fulfilment or neglect of them appeared to be equally unavailing; for all equally perifhed; and partly from the general expectation that no one would furvive a fufficient length of time to undergo trial and punifhment. And many perfons, confidering themfelves already doomed by fate to worfe punifhment than the laws could inflict, determined to enjoy fome of the pleafures of life before the time of fuffering arrived." Thucydides, lib. ii. § 53.

Very fimilar accounts of the diffolute ftate of the public character, attendant on times of peftilence, are related by other writers, who have witneffed thefe calamities. In the interefting defcription of the plague at Florence in the year 1348, given by Boccaccio in the introduction to his Decamerone, many allufions are made to this lawlefs condition of the city. After defcribing the different views which fome perfons adopted as to the mode of felf prefervation; he fays, "others maintained free living to be a better prefervative, and would baulk no paffion or appetite they wifhed to gratify, drinking and revelling inceffantly from tavern to tavern,

tavern, or in private houſes, which were frequently found deſerted by the owners, and therefore common to every one; yet avoiding, with all this irregularity, to come near the infected. And ſuch at that time was the public diſtreſs, that the laws human and divine were no longer regarded; for the officers to put them in force being either dead, ſick, or in want of perſons to aſſiſt them, every one did juſt as he pleaſed." Again, he ſays, " I paſs over the little regard that citizens or relations ſhewed to each other; for their terror was ſuch, that a brother even fled from his brother, a wife from her huſband, and, what is more uncommon, a parent from its own child." From the deſertion of friends, and the ſcarcity of ſervants, who required enormous wages, multitudes died who might have been ſaved, and from mere neceſſity, he obſerves, many cuſtoms were introduced, different from what had before been known in the city. And he adds, it fared no better with the adjacent country; for, to omit the different caſtles about us, which preſented the ſame view, in miniature, with the city, you might ſee the poor diſtreſſed labourers, with their families, without either the interference of phyſicians or help of ſervants, languiſhing on the highways, in the fields, and in their own houſes, and dying rather like cattle than human creatures; and growing diſſolute in their manners like the citizens, and careleſs of every thing, as ſuppoſing every day to be their laſt, their thoughts were not ſo much employed how to improve, as to make uſe of their ſubſtance for their preſent ſupport, &c."

But while the dread of contagion and death have thus contributed to annihilate the beſt feelings of human nature, and to cut aſunder all the moral ties of ſociety, during the prevalence of peſtilence; other paſſions of a ſelfiſh kind were alſo called into action, which overcame this fear, and actually led the people to ruſh into the preſence of contagion, and thus to multiply the victims to its fatal malignity. Avarice was one of theſe miſleading propenſities. M. Bertrand, when deſcribing the effects of the plague at Marſeilles in 1720, remarks that " the avidity to take poſſeſſion of an unexpected inheritance was alſo to many the fatal cauſe of their own deſtruction. Called to the entire ſucceſſion of the wealth of a whole family, to whom perhaps they were very diſtantly related, and impatient to know the extent of their new acquiſitions, they entered, without precaution, into infected houſes, and ſearching indiſcriminately among the effects of the deceaſed, they often found what they ſought not, and paid with their lives the forfeit of their cupidity. Their fatal heritage then devolved to relations yet more remote, fortunate if they could profit by ſuch an example, and not fall equally martyrs to indecent and unreaſonable tranſports. It was not, however, always the legitimate heirs on whom the puniſhment of their avidity fell; it was often thoſe who found *in the effects they ſtole* the juſt forfeit of their crime. In vain had the commandant abſolutely prohibited the removal of any clothes or effects from one houſe to another; a blind and headſtrong rapacity deſpiſed alike theſe wiſe ordonnances and the perils of the contagion." See Bertrand's Hiſtorical Relation of the Plague at Marſeilles, tranſlated by Miſs Plumptre, chap. xix.

Avarice, however, was not the only paſſion which was excited in this extraordinary degree, and contributed to extend the infection. " Another abuſe of a very ſingular nature," ſays M. Bertrand, " occaſioned more than all this partial renewal of the malady. Will it be believed? ſcarcely had the contagion begun ſomewhat to diminiſh in its ravages, when the people, impatient to repair the mortality it had occaſioned, thought of nothing but re-peopling the city by new marriages; like mariners who have been in imminent peril of ſhipwreck, but are no ſooner arrived in port, than, forgetting the danger they have eſcaped, they ſeek, in new pleaſures, to drown the recollection of paſt troubles. Our temples, long ſhut up, were now only opened for the adminiſtration of this ſacrament. A ſpecies of phrenſy ſeemed to have ſeized on both ſexes, which led them to conclude the affair, of all others the moſt important in the world, in the ſpace of twenty-four hours, and to conſummate it almoſt at the ſame inſtant. Widows, whoſe cheeks were yet moiſt with the tears they had ſhed over a dead huſband; conſoled themſelves in the arms of a living one, who perhaps was in like manner ſnatched from them a few days after, and in a few days more they were wedded to a third." Some of the phyſicians imagined that this frantic paſſion was a conſequence of the malady; but M. Bertrand explains it more plauſibly upon the great change of circumſtances which many had undergone; he might alſo have added, the extreme uncertainty of the tenure of life, and the conſequent determination to make the moſt of its pleaſures, which has been noticed above. The numerous marriages, however, thus haſtily concluded, were the occaſion of ſpreading afreſh the fatal infection; ſo that the biſhop determined that no marriage ſhould be licenſed, unleſs the parties demanding it could produce certificates of health from the phyſicians, and as the ſickneſs abated, it became their principal occupation to receive the diſagreeable viſits of thoſe who were frantic to ruſh into the bonds of marriage.

But theſe were not the only moral evils attending the peſtilence, for every ſpecies of crime aggravated the ſufferings of the unfortunate city. " If the people had ſhewn no other ſigns of having forgotten their paſt misfortunes, than the joy which theſe new marriages occaſioned, there would have been no reaſon," ſays M. Bertrand, " to fear that a ceremony, honoured by the firſt miracle of our Saviour, authoriſed by the laws, and neceſſary to ſociety, would irritate the Lord anew againſt us, provided all was conducted in conformity with Chriſtian decency and rectitude. But what was likely to draw down upon us much greater judgments from his anger, were the thefts, the plunderings, and an infinity of other crimes, the horrors of which we dare not here retrace. For theſe their perpetrators promiſed themſelves impunity on the part of men from the troubles of the contagion, and abſolution on the part of heaven, by the favour it had ſhewn them, either in their having eſcaped the diſeaſe entirely, or recovered from it, when it proved mortal to ſo many thouſands of their fellow-citizens. While the arm of the Lord was yet extended over us, a general licence was ſeen to reign among the people, a depravity of morals frightful to think on. Some ſeized on houſes left vacant by the mortality; others forced open thoſe that were ſhut up, or guarded by perſons incapable of reſiſtance. They entered thoſe where, perhaps, there remained only one perſon languiſhing with the malady, forced open the cloſets and drawers, and took away whatever they found moſt precious, often carrying their infamy to the length of delivering themſelves from an importunate witneſs, who had otherwiſe but a few moments to live. Theſe enormous crimes, much more frequent in the height of the malady than in its decline, were generally committed either by thoſe who ſerved the ſick, who carried away the dead, or who attended at the hoſpitals. By the declarations which theſe people, from their ſituations, were able to wring from the dying, they were informed of the ſtate of their houſes; nay, it often happened, that by the ſame means they got poſſeſſion of their keys. This licence was yet greater in the country, where the diſtance of the baſtilles from each other, and the opportunity of going to them

them in the night, favoured these criminal expeditions." Loc. cit.

These extracts present a picture of the moral evils which, in conjunction with the physical distresses attendant upon so severe and fatal a malady, render a season of pestilence the most formidable calamity that visits mankind. If the reader is desirous of a more ample detail of its horrors, he may peruse the whole of M. Bertrand's volume; the introduction of Boccaccio, before quoted; the Traité de la Peste, published by the physicians of Marseilles; the Loimologia of Dr. Hodges; and particularly an interesting Journal of the Plague Year, being observations or memorials of the most remarkable occurrences, as well public as private, which happened in London during the last great visitation in 1665. This journal, indeed, has been said to be the production of Daniel de Foe, and not, as its title page expresses, "written by a citizen, who continued all the while in London;" but it contains a true picture of the general consequences of the pestilence.

PLAGUE-*Water*, *Aqua Epidemica*, is one of the compound waters of the shops, distilled from mint, rosemary, angelica roots, &c.

PLAIAR, in *Geography*, a town of European Turkey, in Romania; 6 miles S. of Gallipoli.

PLAID, BELTED, in *Military Language*, the ancient garb of the Scots Highlanders, and still worn by some of our Highland regiments. The belted plaid consists of twelve yards of tartan, which are plaited, bound round the waist by a leathern belt, the upper part being attached to the left shoulder.

PLAIN, PLANUS, an epithet applied to various things, generally importing them to be smooth, even, level, or superficial, or simple, obvious, or the like.

In these senses, the words stand opposed to rough, solid, laboured, enriched, &c.

It is a maxim in heraldry, that the plainer the coat, the nearer to antiquity. Plain coats are such as are least encumbered with figures, or charges, and which have nothing in them but what is natural.

PLAIN, in *Heraldry*, is sometimes used for the point of the shield, when coupled square, a part remaining under the square, of a different colour, or metal, from the shield.

This has been sometimes used as a mark for bastardy, and called *champaigne:* for when the legitimate descendants of bastards have taken away the bar, fillet, or traverse, borne by their fathers, they are to cut the point of the shield with a different colour, called *plain*.

PLAIN, used substantively, in *Perspective*, *Mechanics*, *Astronomy*, *&c.* See PLANE.

PLAIN *Angle*, in *Geometry*, is an angle contained under two lines or surfaces.

It is so called in contradistinction to a *solid* angle.

PLAIN *Figure*. See PLANE.

PLAIN *Triangle*, is a triangle included under three right lines, or surfaces; in opposition to a *spherical*, and a *mixt* triangle.

PLAIN *Trigonometry* is the doctrine of plain triangles, their measures, proportions, &c.

PLAIN *Chant*, and PLAIN *Song*, in *Music*. See CHANT, and CANTO FERMO.

PLAIN *Counterpoint*, is rigidly composed of common chords of note against note, without discords, and in characters of the same length, as in calvinistical and parochial psalmody. But, provided long and short syllables are distinguished, as in the 104th psalm, and the notes in vocal or instrumental music are struck together, it may still be called plain counterpoint. Very pleasing airs, à 4, in the Greek church, are sung in this manner, not only note against note, but syllable against syllable, which renders the words well accented, and very intelligible.

PLAIN *Descant*. See DESCANT.

PLAIN *Glass*, or *Mirror*, in *Optics*, is a glass or mirror whose surface is flat, or even. See the phenomena and laws of plain mirrors, under the article MIRROR.

PLAIN *Scale* is a thin ruler, whereon are graduated the lines of chords, sines, tangents, secants, leagues, rhumbs, &c. of ready use in most parts of the mathematics, chiefly in navigation.

See its description and use under SCALE.

PLAIN *Tyle*. See TYLE.

PLAIN *Chart*, in *Navigation*, is a sea-chart, wherein the meridians and parallels are represented by parallel straight lines; and where, of consequence, the degrees of longitude are the same in all the parallels of latitude.

See the properties, construction, &c. of this chart under CHART.

PLAIN *Sailing*, is the art of working the several cases and varieties in a ship's motion on a plain chart.

Plain sailing is founded on the supposition of the earth being a plane or flat; which, though notoriously false, yet, places being laid down accordingly, and a long voyage broken into many short ones, the voyage may be tolerably performed by it, near the same meridian.

In plain sailing it is supposed that by the rhumb line, meridian, and parallel of latitude, there always will be formed a right-angled triangle; and that so posited, as that the perpendicular side may represent part of the meridian, or north and south line, containing the difference of latitude; the base of the triangle represent the departure; and the hypothenuse, the distance sailed. The angle at the vertex is the course, and the angle at the base, the complement of the course; any two of which, with the right-angle, being given, the triangle may be protracted, and the other three parts found.

For the doctrine of plain sailing, see SAILING.

PLAIN *Table*, in *Geometry*, *&c.* an instrument used in the surveying of land; whereby the draught, or plan, is taken on the spot, without any future protraction, or plotting.

The plain table, represented *Plate* VI. *Surveying*, *fig.* 1. consists of a parallelogram of wood about fifteen inches long and twelve broad; round this goes a boxen jointed frame, by means of which a sheet of paper is fastened tight to the table, so that lines may be conveniently drawn upon it.

On each side of the frame, which may be put on either side upwards, towards the inward edge, are scales of inches subdivided, for the ready drawing of parallel lines. Beside which, on one side are projected the 360 degrees of a circle, from a brass centre in the middle of the table (each degree halved) with two numbers to every tenth degree, the one expressing the degree, the other its complement to 360, to save subtraction: on the other side are projected the 180 degrees of a semicircle, from a brass centre in the middle of the table's length, and at $\frac{1}{4}$th of its breadth; each degree halved, and every tenth noted with two numbers, *viz.* the degree and its supplement, to 180°. To one side of the table is fitted a compass, for placing the instrument by; and the whole is fixed by a socket, upon a three-legged staff for a stand, on which it is turned round, or fastened by a screw, as occasion requires. Lastly, to the table belongs an index, which is a ruler at least sixteen inches long, and two broad; usually graduated with scales, &c. and having two sights perpendicularly placed on its extremities; and a sloped edge, called the fiducial edge.

PLAIN

Plain *Table, Use of the.*—To take an angle by the plain table; or to find the distance of two places accessible from the same third.

Suppose D A, D B, (*fig.* 2.) the sides of the angle required: or A B the distance required. Place the instrument horizontally, as near the angle as possible; and assume a point in the paper on the table, *v. gr. c.* To this point apply the edge of the index, turning it about this and that way till through the sights you see the point B: and, in this situation of the ruler, draw by its edge the line *c e* indefinitely.

After the same manner turn about the index on the same point till through the sights you see the point A; and draw the right line *c d* indefinitely. Thus have you the quantity of the angle laid down.

Measure the lines D A, D B, with a chain; and from a scale set off the measures thus found on the respective lines; which suppose to reach from *c* to *b*, and from *c* to *a*. Thus will *c b* and *c a* be proportional to D B and D A. Transfer the distance *a b* to the same scale, and find its length; the length, thus found, will be the length, or distance of A B required.

2. *To find the distance of two places, one of which is inaccessible, by the plain table.*—Suppose the distance required A B (*fig.* 3.), and A the accessible point. 1. Place the plain table in C; look through the sights till you see A and B; and draw *a c* and *c b*. Measure the distance from your station to A; and set it off from the scale upon *c a*. 2. Remove the table to A, where place it so as that the point *a* representing A, and the index laid along the line *a c*, you see backwards the former station C. [Note, in this fixing the instrument, lies the use of the compass; for the needle will hang over the same degree of the card in the first and the second case; so that some set the instrument by the needle alone; others only use it to shorten the trouble, by bringing the instrument nearly to its due position by means of it; and then fixing for good by the back sight]. 3. The instrument fixed, turn the sights to B; and draw the line *a b*. 4. On the scale measure the interval *a b*; which will be the distance of A B required.

3. *To find the distance of two inaccessible places by the plain table.*—Suppose the distance of A B (*fig.* 4.) required. 1. Choosing two stations in C and D; in the first, C, place the plain table; and through the sights look to D, B, and A, drawing, by the edge of the index, the lines *c d*, *c b*, *c a*. 2. Measure the distance of the stations C, D; and set this off from a scale on *c d*. 3. Removing the table from C, fix it in D; so as the point *d* hanging over the place D, and the index lying along the line *c d*, through the sights you see the former station C. The instrument thus fixed, direct the sight to A and B, and draw the right lines *d a* and *d b*; lastly, find the distance of *a b* on the scale, and this will be the distance of A B required. After the same manner may the distance of any number of places be found from two stations; and thus may a field, part of a country, &c. be surveyed.

4. *To take the plot of a field from one station, whence all the angles may be seen with the plain table.*—Placing the instrument in the station, assume a point in the paper, to represent the same, *v. gr.* O (*fig.* 5.); laying the edge of the index to this point, direct it to the several angles of the field, A, B, C, D, E, F, &c. and draw indefinite lines by its edge towards every angle; *viz.* O *a*, O *b*, O *c*, &c.; measure the distance of each angle from the station, *viz.* O A, O B, O C, O D, &c. and from a scale set these off from O on their correspondiug lines; the extremities hereof will give points, which, being connected by lines, will represent the field.

5. *To take the plot of a field, wood, or the like, by going round the same, with the plain table.*—Place the instrument horizontally at the first angle, *v. gr.* A: the needle being on the meridian of the card; assuming a point on the paper to represent it; to that point lay the index, directing it till through the sights you see a mark in the angle B, and draw an indefinite line along it; measure the distance of A and B, and from a scale set it off on the line thus drawn; the extremity of this distance will represent the point B. Remove the instrument to B, where set it so as that the needle hang over the meridian of the card; and so as the index lying along the line last drawn, you see the former station A through the sights: here fasten it, lay the index to the point B, and turn it till through the sights you see the next angle C; in this situation draw a line, as before, measure the distance B C, and set it off from a scale on the line. Remove the instrument to C, where fixing it by the needle, and the back sight, as before, turn the index on the point C till you see the next angle D; draw the line, measure, and set off the distance C D, as before, and remove the plain table to E; where fix it, as before; look to the next angle F, draw the line, measure and set off the distance, &c.

In this manner having compassed the whole field, you will have its whole perimeter plotted on the table; which may be now cast up, and its contents found, as in the article Surveying.

Manner af shifting paper on the plain table.—When in large parcels of grounds the plot is found to exceed the dimensions of the plain table, and to run off from the paper, the sheet must be taken off the table, and a fresh one put on: the way of managing which shifting is as follows: suppose H, K, M, Z, (*fig.* 6.) the limits of the plain table; so that having laid down the field from A to B, thence to C and D, you want room, the line D E running off the paper; draw as much of the line D E as the paper will well hold; *viz.* D O. And by means of the divisions on the edge of the frame, draw the line P Q through O, parallel to the edge of the table H M; and through the point of intersection O, draw O N parallel to M Z. This done, take off the frame, remove the sheet, and put a fresh one (*fig.* 7.) in its stead; drawing on it a line R S near the other edge parallel thereto. Then lay the first sheet on the table, so that the line P Q lie exactly on the line R S, to the best advantage, as at O. Lastly, draw as much of the line O D, on the fresh sheet, as the table will hold; and from O continue the remainder of the line D to E. From E proceed with the work as before to F, G, and A.

Use of the plain table, as a theodolite, semicircle, or circumferentor.—The great inconveniency of the plain table is, that its paper renders its use impracticable in moist weather. Even the dew of the morning and evening is found to swell the paper considerably, and, of consequence, to distort the work. To avoid this inconvenience, and render the instrument useful in all weathers; by leaving off the paper, and setting up a pin in the centre, it becomes a theodolite, a semicircle, or a circumferentor, and is applicable like them.

The plain table, stripped of its paper, becomes either a theodolite, or a semicircle, as that side of the frame, which has the projection of the degrees of a circle, or a semicircle, is turned upwards. If it be to serve for a theodolite, the index (the plain table turning on any point as a centre) is constantly to turn about the brass centre-hole in the middle of the table.

If it be for a ſemicircle, it muſt turn on the other braſs centre-hole; in both caſes it is done by means of a pin raiſed in the holes. When the plain table is to ſerve as a circumferentor, ſcrew the compaſs to the index, and both of them to the head of the ſtaff, with a braſs ſcrew-pin fitted for the purpoſe; ſo that the ſtaff and table ſtanding fixed, the index, ſights, &c. may be turned about, and *vice verſâ.*

To take an angle by the plain table, conſidered as a theodolite.—Suppoſe the quantity of the angle E K G (*fig.* 8.) required. Place the inſtrument at K, the theodolite ſide of the frame upwards, laying the index on the diameter. Turn the whole inſtrument about, the index remaining on the diameter till through the ſights you ſpy E. Screw the inſtrument faſt there, and turn the index on its centre till through the ſights you ſpy G.

The degree here cut on the frame by the index, is the quantity of the angle ſought; which may be laid down on paper by the rules of common protraction.

Thus you may proceed to do every thing with the plain table, as with the common theodolite.

To take an angle with a plain table, conſidered as a ſemicircle.—Proceed in the ſame manner with the inſtrument, conſidered as a ſemicircle, as when conſidered as a theodolite; only laying the ſemicircular ſide upwards, and turning the index on the other centre-hole in the middle of the length, and at about one-fourth of the breadth of the table.

To take an angle with the plain table, conſidered as a circumferentor.—Suppoſe the former angle E K G required. Place the inſtrument at K, the fleur-de-lis towards you. Direct the ſights to E, and obſerve the degree cut by the ſouth end of the needle, which ſuppoſe 296. Turn the inſtrument about, the fleur-de-lis ſtill towards you, and direct the ſight to G, noting the degree cut by the other end of the needle, which ſuppoſe 182. Subtract the leſs from the greater, the remainder, 114°, is the quantity of the angle ſought. If the remainder chance to be more than 180°, then it muſt be again ſubtracted from 360. This ſecond remainder will be the angle required; which may be protracted, &c. as under PROTRACTOR. Thus you may proceed to do every thing with the plain table, as with the common circumferentor.

PLAIN *Place*, in *Geometry*, *locus planus*, or *locus ad planum*, is a term which the ancient geometricians uſed for a geometrical locus, when it was a right line, or a circle, in oppoſition to a ſolid place, which was an ellipſis, parabola, or hyperbola.

Theſe plain loci the moderns diſtinguiſh into *loci ad rectum*, and *loci ad circulum.* See LOCUS.

PLAIN *Problem*, in *Mathematics*, is ſuch a one as cannot be ſolved geometrically, but by the interſection either of a right line and a circle, or of the circumferences of two circles.

Such is the problem following. Given the greateſt ſide, and the ſum of the other two ſides, of a right-angled triangle: to find the triangle. Such alſo is this, to deſcribe a trapezium that ſhall make a given area of four given lines.

Such problems can only have two ſolutions, becauſe a right line can only cut a circle, or one circle cut another in two points.

PLAIN *du Nord*, in *Geography*, a town on the N. coaſt of Hiſpaniola; 13 miles E.S.E. of Port de Paix.

PLAINFIELD, a townſhip of America, formerly *St. Andrew's*, in Caledonia county, Vermont, 100 miles N.E. from Bennington; containing 543 inhabitants.—Alſo, a townſhip of Hampſhire county, Maſſachuſetts, incorporated in 1785, and containing 977 inhabitants; 122 miles W. of Boſton.—Alſo, a townſhip in Northampton county, Pennſylvania, containing 1439 inhabitants.—Alſo, a townſhip in the N.W. corner of Cheſhire county, New Hampſhire, on the E. bank of Connecticut river, which ſeparates it from Hartland in Vermont, incorporated in 1761, and containing 1463 inhabitants.—Alſo, a poſt-town in the S.E. part of Windham county, Connecticut, on the E. ſide of Quinabaug river, which divides it from Brooklyn and Canterbury. The ſoil is generally rich, and well cultivated, and well watered by the Quinabaug and Mooſup rivers, together with many brooks and rivulets. It has two congregational meeting-houſes, and an academy, with three handſome buildings appropriated to its uſe. The ſame was ſettled in 1689, and contains 1738 inhabitants; 14 miles N.E. from Norwich.

PLAINT, PLAINTE, in *Law*, the propounding or exhibiting any action, real or perſonal, in writing.

Hence, the party making this plaint is called plaintiff.

PLAINTAIN *Garden River*, in *Geography*, a river at the E. end of the iſland of Jamaica, and N. by W. of Point Morant. It has at its mouth a kind of bay, and on it, within land, is the town of Bath.

PLAINTE, in the *Ancient Cuſtoms of France*, was a requeſt, or petition, preſented to the king, againſt the judges of the provinces, and afterwards againſt bailiffs and ſeneſchals for denying juſtice, or for rendering judgment contrary to the laws of the realm.

For in thoſe days there was no appeal from their deciſions; but they all pronounced in the dernier reſort; ſo that the plainte was not directed againſt the party, but againſt the judge; who was cited to ſee his own ſentence declared null.

This was a kind of ſupplement to the way of appeals, which was then ſhut up. The plaintes, in the Capitulars of Charlemagne, are called *blaſphemiæ.*

PLAINTIFF, in *Law*, he that ſues or complains, in an aſſize, or in an action perſonal; as in an action of debt, treſpaſs, deceit, detinue, and the like.

Plaintiff ſtands oppoſed to *defendant.*

PLAJOW, in *Geography*, a town of the iſland of Borneo; 150 miles N. of Banjar-Maſſin.

PLAISANCE, a town of France, in the department of the Gers, and chief place of a canton, in the diſtrict of Mirande; 22 miles W. of Auch. The place contains 1260, and the canton 8049 inhabitants, on a territory of $217\frac{1}{2}$ kiliometres, in 20 communes.

PLAISANCE, a town on the middle of the neck of the north peninſula of the iſland of Hiſpaniola; 12 leagues S.W. of Cape François.

PLAISANO, a town of Naples, in Calabria Ultra; ſix miles N. of Oppido.

PLAISE, in *Ichthyology*, the Engliſh name for the fiſh, called by authors *plateſſa* and *paſſer lævis*, by ſome *quadratulus*, and the *pleuronectes plateſſa* of Linnæus.

It is a flat fiſh, of a duſky olive-colour, ſpotted with red on the back, and white on the belly.

The plaiſe are common on moſt of our coaſts; the beſt and largeſt are taken off Rye, on the coaſt of Suſſex, and alſo off the Dutch coaſts. They ſpawn in the beginning of February.

PLAISTER, in *Building*. See PLASTER, MORTAR &c.

PLAISTER, *Caſting in*. See CASTING.

PLAISTER, in *Medicine*. See EMPLASTRUM, and PLASTER.

PLAISTERED WALLS. See WALL.

PLAISTOW,

PLAISTOW, in *Geography*, a town of America, in Rockingham county, New Hampſhire, containing 424 inhabitants.

PLAISTOW, a village in the pariſh of Weſt-Ham, Eſſex. See WEST-HAM.

PLAITING, in *Rigging*, denotes braided cordage, made by rope-yarn, &c. twiſted together, and then laid one over the other alternately; or the end of a rope opened, and the ſtrands placed together in the ſame manner.

PLAK, in *Geography*, a town of Hungary; five miles S. of Caſchau.

PLAN, a repreſentation of ſomething drawn on a plane. Such are maps, charts, and ichnographies.

PLAN, in *Architecture*, is particularly uſed for a draught of a building; ſuch as it appears, or is intended to appear on the ground; ſhewing the extent, diviſion, and diſtribution of its area into apartments, rooms, paſſages, &c.

The plan is the firſt device or ſketch the architect makes; it is alſo called the *ground plot, platform,* and *ichnography*, of the building.

PLAN, *Geometrical*, is that in which the ſolid and vacant parts are repreſented in their natural proportion.

PLAN, *Raiſed*, is that where the elevation, or upright, is ſhewn, upon the geometrical plan, ſo as to hide the diſtribution. See ELEVATION.

PLAN, *Perſpective*, is that conducted and exhibited by degradations, or diminutions, according to the rules of perſpective.

To render plans intelligible, it is uſual to diſtinguiſh the maſſives with a black waſh. The projectures on the ground are drawn in full lines, and thoſe ſuppoſed over them in dotted lines. The augmentations or alterations to be made are diſtinguiſhed by a colour different from what is already built; and the tints of each plan are made lighter as the ſtories are raiſed.

In large buildings it is uſual to have three ſeveral plans for the firſt three ſtories.

PLAN *of a Baſtion*, in the *Military Art*, is the ſame with the face of the baſtion.

PLAN, in *Ship Building*, the ſection of a ſhip, as deſigned upon paper, previouſly to the actual building of which, three are the chief, *viz*. the plan of elevation or ſheer-plan, the horizontal or half-breadth-plan, the plan of projection or body-plan; theſe three compoſe the *ſheer-draught*. But it muſt be obſerved, that the extreme length, breadth, and height muſt be determined; by which the three plans aforeſaid may be delineated. Theſe may be called the outlines, and the ſeveral parts contained within them may be delineated ſo as to anſwer the intended purpoſe; and likewiſe have a diſtinct view of the whole deſign, ſo that any inconveniencies attending ſuch a diſpoſition may be eaſily remedied, and the true dimenſions of every particular may then be had upon the draught.

The delineating a ſhip upon a plan is called drawing, and the repreſentation is called a draught. See SHIP-BUILDING.

PLAN, in *Geography*, a town of Bohemia, in the circle of Pilſen; 66 miles W.S.W. of Prague. N. lat. 49° 52′. E. long. 12° 47′.

PLAN, *El*, a town of Spain, in Aragon; 15 miles N. of Ainſa.

PLAN *Ober*, a town of Bohemia, in the circle of Bechin; 12 miles W.S.W. of Crumau.

PLANA, a town of Sweden, in Weſt Gothland; 30 miles E.N.E. of Uddevalla.

PLANA, *La*, a town of Spain, in Valencia; 22 miles E. of Segorbe.

PLANA, or *Tabarca*, a ſmall iſland in the Mediterranean, near the coaſt of Valencia, S.E. of cape St. Pola. N. lat. 37° 11′. W. long. 0° 34′.

PLANARIA, in *Ancient Geography*, an iſland ſituated on the coaſt of Italy, in the Ligurian ſea, 60 miles from that of Corſica. Pliny.

PLANARIA, in *Vermeology*, a genus of worms of the order Inteſtina. The generic character is; body gelatinous, flattiſh, with a double ventral pore; the mouth is terminal. There are forty-nine ſpecies, divided into four ſections, diſtinguiſhed as to the number of their eyes or their being without eyes. The animals comprehended under this genus nearly reſemble leeches, and like them live in freſh waters.

A. *Without Eyes*.

Species.

STAGNALIS. Ovate, brown, the fore-part pale. It inhabits the ſtagnant waters; the body is opaque, a little pointed on the fore-part, pellucid, with two milk-white ſpots; the eggs are numerous, whitiſh, placed at the ſides.

NIGRA. Oblong, black, and truncate on the fore-part. It inhabits rivers.

BRUNNEA. Oblong, reddiſh-brown, with a longitudinal black line.

CILIATA. Body long, depreſſed, and ciliate. It is found in ſtagnant waters, under duck-weed: it is a very curious creature; the body is grey, appearing as if compoſed of granulations, with moveable briſtles; the organ on the forepart rotatory.

GULO. Body long, pellucid, and truncate before. This alſo is found in ſtagnant waters, under duck-weed; reſembles the laſt, but is without the fringe, the margin all round is teſſellate, with extremely fine ſtriæ; it ſwallows the ſeveral ſpecies of the Cyclidium which inhabit the ſame waters, and after a time diſcharges them again. See CYCLIDIUM.

PUNCTATA. Body long, round, and green. Found early in the ſpring in wet meadows. The body is obtuſe before, a little pointed behind, ſprinkled with ſmall black dots, and containing five red ſpherical pellucid eggs.

FLACCIDA. Body long, reddiſh-brown, with tranſverſe white lines, and a lateral one. It is found among heaps of ſhells in the bays of Norway; when at reſt it rolls itſelf up ſpirally, and then gradually dilates itſelf.

ROSEA. Body long, red. Found in the bays of Norway,

ANGULATA. Body long, reddiſh-brown, with two white angles on the fore-part. Found in the ſandy bottoms of the ocean.

RUBRA. Body oblong, depreſſed, and of pale red. It inhabits the deeps of the Greenland ſhores. The body is marked with fine tranſverſe lines above.

VIRIDIS. Body oblong, above convex, with tranſverſe white ſtreaks. Found among the roots of marine fuci.

OPERCULATA. Body ſubovate, grey, and furniſhed beneath with a lid which conceals the exſertile tube. Inhabits, though rarely, the ſandy ſhores, particularly among fuci, in the bays of Norway. In appearance it ſeems to reſemble a coffee berry, and moves by bending in its margin, and by means of its marginal folds fixes itſelf to and aſcends other bodies.

SUBULATA. Body long, pointed on the fore-part, and truncate behind. It is found in great plenty among marine confervæ in Greenland, and the muddy bottoms of holes in rocks which conſtantly retain water, and proceeds with a ſerpentine kind of motion; but if the proboſcis be touched it contracts itſelf ſuddenly into a minute cube.

QUADRAN-

Quadrangularis. Body pale, ovate, very ſharp-pointed before, and winged with ſmall curled longitudinal membranes. It is found in ditches, among duck-weed; is very ſoft, pellucid, of a changeable form, and moves like a ſlug, leaving a ſlime on the bodies it paſſes over; when it meets another animal it draws itſelf in like a ſnail.

Bicornis. Body oval, lanceolate, obtuſe at each end, grey cinereous, dotted with black, with two very ſhort divergent tubes on the fore-part. It is a native of thoſe waters in Belgium that are covered with duck-weed: when irritated it fixes itſelf to other bodies, like the leech, by means of its tubes.

Grisea. Body grey, dilated, elongated and pointed on the fore-part; the hind part is abbreviated and pointed. It inhabits the waters of lakes, among confervæ.

Fulva. Depreſſed, broadiſh, and pointed at each end, with a long black ſpot down the middle.

Viridata. Oblong, round, green, and ſomewhat pointed at each end. It inhabits wet meadows in the autumn.

B. *With a ſingle Eye.*

Glauca. The body of this is a little elongated, and cinereous, with a white iris. It is about a line long, pointed before and broadiſh behind, with ſometimes a double black line in the middle of the back and meeting at the ends. A native of the waters.

Lineata. Body long, above convex and cinereous, with a longitudinal pale line. This ſpecies is found on the ſhores of the Baltic; is about a line and a half long; beneath it is of a pale colour, with a brown patch in the middle, tapering before and dilated behind.

Rutilans. Linear, with a black eye, and tapering to a point before. This is found in the Baltic, among fuci.

C. *With two Eyes.*

* Fusca. Black-brown, with a ſemi-pellucid whitiſh ſpot above the tail. It is found in ſlow ſtreams upon and about aquatic plants. When at reſt the body is circular, and ſeldom above a line in length; when in motion it is linear, and nearly half an inch long; its motion is uniform, ſmooth, by gliding along the ſtream.

* Lactea. Body depreſſed, oblong, whitiſh, and truncate on the fore-part. It is found in ponds and rivulets, but only in the ſummer ſeaſon, and among aquatic plants. When in motion it is about an inch long: the body is marked with a white ſpot in the middle, the purple viſcera elegantly branching round it; the margin is white and very tranſparent.

Torva. Depreſſed, oblong, cinereous, or black and whitiſh beneath; the iris is white, it is ſomething more than half an inch long.

Crenata. Depreſſed, ovate-oblong, pale, with a crenulate margin. A native of Denmark.

Tentaculata. Depreſſed, oblong, cinereous, and tubular on the fore-part. Inhabits ſtagnant waters, and three-quarters of an inch long.

Helluo. Body ovate, round, green. It inhabits wet meadows, and is not a quarter of an inch long.

Obscura. Ovate-oblong, white, and obtuſe at both ends. It is found in ſtagnant waters, and is about a line long, and ſub-pellucid.

Rostrata. Oblong, hyaline; elongated at the extremity; the eyes are red. It inhabits marſhes; about a line long; whitiſh, but with a purpliſh maſs in the middle.

Atomata. Flat, membranaceous, white, with ſcattered rufous ſpecks above. It is a native of the bays of Norway, and reſembles the Doris *oblevata*; which ſee.

Cornuta. Flat, rather oblong, with a tentaculum or feeler from each ſide of the head. It inhabits the bays of Norway.

Radiata. Oblong, rufous, with a white roſe-like ſpot on the back. It inhabits wet woods, and reſembles the Vorticella radiata.

Strigata. Oblong, pale, with three longitudinal lines. It inhabits wet marſhes: the body is marked with rufous ſtreaks.

Grossa. Cylindrical, white with black eyes, and pointed at both ends. It is found among aquatic plants; it varies in ſize; the body is pellucid, with from five to more than thirty large ſpherical eggs.

Linearis. Long, roundiſh, and pale yellow. It inhabits wet hollows of woods, about a line and a half long, and ten times as narrow; the margin is pellucid and white.

Terrestris. Linear; above convex, cinereous; beneath white. It is found in moiſt clumps among moſs; it contracts and expands itſelf like a leech, and moves like a ſnail; body opaque and viſcous.

Tetragona. Pale yellow, with four quadrangular lamellæ. It inhabits clear ſtagnant waters.

Capitata. Oblong, cinereous, with a diſtinct head. Found in the Baltic.

Caudata. Body rounded before, and tapering into a tail behind. Inhabits the ſhores of Greenland, among ſea-wrack.

Auriculata. Oblong, truncate and emarginate before, and acute behind. Found in the ſea-water in Norway. It is a very minute worm, ſcarcely viſible to the naked eye.

Filaris. Linear, with a filiform contractile tail. Found on the Madrepora *prolifera*, which ſee; it is about an inch long and a line broad.

Lingua. Pellucid, brown-cinereous, and very obtuſe at both ends. Found in fiſh-ponds in the autumn.

Gesserensis. Body long, green, and rufous behind the head. This is a native of Denmark, on the Fucus furcellatus.

E. *With four Eyes.*

Marmorata. Oblong, blueiſh-grey or pale. Found in wet ditches, about half a line long; inteſtines glomerate, white, with a large round yellow ſpot in the middle.

Candida. Body long, whitiſh, with a clear white line down the middle. It inhabits the ſhores of Greenland, under ſtones, and is about two or three inches long.

Truncata. Pale reddiſh, broadly truncate before, and rather ſharp behind.

F. *Eyes numerous.*

Tremellaris. Flat, membranaceous, pale yellow, with a ſinuate margin. It is found in the Baltic, and reſembles a Tremella, and is nine inches long. The body of this worm is greyiſh above; the diſk is yellowiſh, with a pinnate line, in the middle, and behind this two white lunules; beneath it is whitiſh, with three milk-white ſpots.

PLANCHES, in *Geography*, a town of France, in the department of the Jura, and chief place of a canton, in the diſtrict of Poligny; 16 miles S.E. of Poligny. The place contains 333, and the canton 4218 inhabitants, on a territory of $117\frac{1}{2}$ kiliometres, in 10 communes.

PLANCHIER, or Plancere, in *Architecture*, the under part of the corona, or drip; making the ſuperior part of the corniche, between two cymatiums.

PLANCKEN, in *Geography*, a town of Pruffia, in Natangen; 10 miles S.W. of Brandenburg.

PLANCOET, a town of France, in the department of the Northern Coafts, and chief place of a canton, in the diftrict of Dinan; 8 miles N. W. of Dinan. The place contains 635, and the canton 13,522 inhabitants, on a territory of $202\frac{1}{2}$ kiliometres, in 12 communes.

PLANCY, a town of France, in the department of the Aube; 8 miles W. of Arcis-fur-Aube.

PLANE, Planum, in *Geometry*, denotes a plain figure, or a furface lying evenly between its bounding lines.

Wolfius defines plane, a furface, from every point of whofe perimeter a right line may be drawn to every other point in the fame.

As the right line is the fhorteft extent from one point to another, fo is a plane the fhorteft extenfion between one line and another.

Planes, *Oblique*. See Oblique.

Planes, *Parallel*. See Parallel.

Planes are frequently ufed in *Aftronomy*, &c. for imaginary furfaces, fuppofed to cut, and pafs through, folid bodies, and on this foundation it is, that the whole doctrine of conic fections, and of the fphere, turns.

When a plane cuts a cone parallel to one of its fides, it makes a *parabola;* when it cuts the cone parallel to its bafe, it makes a *circle*. See each refpectively.

The fphere is wholly explained by planes, imagined to cut the celeftial luminaries, and to fill the areas or circumferences of the orbits; and they are differently inclined to each other; and by us the inhabitants of the earth, the plane of whofe orbit is the plane of the ecliptic, their inclination is eftimated with regard to this plane. See Planets.

Plane, in *Mechanics*. A *horizontal* plane is a plane level or parallel to the horizon.

The determining how far any given plane, &c. deviates from a horizontal one, makes the whole bufinefs of *levelling;* which fee.

Plane, *Inclined*, is a plane which makes an oblique angle with a horizontal plane.

A machine has been contrived for meafuring the acceleration of a ball down an inclined plane, and comparing it with that found in bodies falling at liberty. See its defcription in Mem. de l'Acad. Roy. de Scienc. 1699, p. 343.

The doctrine of the motion of bodies on inclined planes makes a very confiderable article in mechanics; the general principle of it has been already illuftrated under Mechanical *Powers*, and the fubftance of it is as follows:

Laws of Defcent of Bodies on inclined Planes.—I. If a body be placed on an inclined plane, its relative gravity will be to its abfolute gravity as the height of the plane, *e. gr.* A B (*Plate* XXXV. *Mechan. fig.* 1.) to its length A C. For, the conftruction being as in the figure, it is evident that the abfolute gravity, tending in a direction perpendicular to the horizon, is to the relative gravity in the direction of the plane, as D F : F G or D E, *i. e.* becaufe the triangles D E F and B A C are equiangular, :: C A : A B.

Hence, 1. Since the ball D only gravitates on the inclined plane with its relative gravity, the weight L, applied in a direction parallel to the length of the plane, will retain or fufpend it, provided its weight be to that of the ball, as the altitude of the plane B A is to its length A C.

2. If the length of the plane C A be taken for the whole fine or radius, A B will be the fine of the angle of inclination A C B. The abfolute gravity of the body, therefore, is to its refpective gravity applied to the inclined plane; and, therefore, alfo the weight D to the weight L acting according to the direction D A, which fuftains it, as the whole fine is to the fine of the angle of inclination.

3. Hence the refpective gravities of the fame body on different inclined planes, are to each other as the fines of the angles of inclination.

4. The greater, therefore, the refpective gravity is, the greater is the angle of inclination.

5. As, therefore, in a vertical plane, where the inclination is greateft, *viz.* perpendicular; the refpective gravity degenerates into abfolute; fo in a horizontal plane, where there is no inclination, the refpective gravity vanifhes: and hence it appears, that the inclination of the plane may be fo fmall, that the greateft weight may be fuftained on it by the fmalleft power.

II. To find the fine of the angle of inclination of a plane, on which a given power will be able to fuftain a given weight. Say, as the weight is to the given power, fo is the whole fine to the fine of the angle of inclination of the plane. Thus, fuppofe a weight of 1000 be to be fuftained by a power of 50, the angle of inclination will be found 2° 52′.

III. If the weight L defcend according to the perpendicular direction A B, and raife up the weight D in a direction parallel to the inclined plane, the height of the afcent of D will be to that of the defcent of L, as the fine of the angle of inclination C to the whole fine.

Hence, 1. The height of the defcent C D of the weight L, is to the height of afcent D H of the weight D, reciprocally as the weight D to the equivalent weight L.

2. Since then $CD \times L = DH \times D$, and the actions of the equiponderating bodies D and L are equal; the moments of the weights D and L are in a ratio compounded of their maffes, and the altitudes through which they afcend or defcend in a plane either inclined or perpendicular.

3. The powers that raife weights through altitudes reciprocally proportional to them, are equal. This Des Cartes affumes as a principle whereby to demonftrate the power of machines.

Hence we fee why a loaded waggon is drawn with more difficulty up an inclined than on an horizontal plane: as being preffed with a part of the weight which is to the whole weight in a ratio of the altitude of the plane, to its length.

IV. Weights E and F, *fig.* 2, equiponderating upon inclined planes A C and C B of the fame height C D, are to each other as the lengths of the planes A C and C B.

S. Stevinus gives a very pretty demonftration of this theorem, which, for its eafinefs and ingenuity, we fhall here add. Put a chain, whofe parts do all exactly weigh in proportion to their length, over a triangle G I H (*fig.* 3.); it is evident the parts G K and K H do balance each other. If then I H did not balance G I, the preponderating part will prevail; and there would arife a perpetual motion of the chain about G I H: but this being abfurd, it follows that the parts of the chain I H and G I, and confequently all other bodies which are as the lengths of the planes I H and I G, will balance each other.

V. A heavy body defcends on an inclined plane, with a motion uniformly accelerated.

Hence, 1. The fpaces of defcent are in a duplicate ratio of the times, and likewife of the velocities; and therefore in equal times they increafe according to the unequal numbers, 1, 3, 5, 7, 9, &c.

2. The fpace paffed over by a heavy body defcending on an inclined plane is fubduple of that which it would pafs over in the fame time, with the velocity it has acquired at the end of its fall.

3. Heavy bodies, therefore, defcend by the fame laws on inclined planes as in perpendicular planes. Hence it was, that Galileo, to find the laws of perpendicular defcent, made his experiments on inclined planes, becaufe the motions are flower in the latter than the former; as in the following theorem.

VI. The velocity of a heavy body defcending on an inclined plane, at the end of any given time, is to the velocity which it would acquire in falling perpendicularly in the fame time, as the height of the inclined plane is to its length.

VII. The fpace paffed over by a heavy body on an inclined plane A D (*fig.* 4.), is to the fpace A B it would pafs over in the fame time in a perpendicular plane, as its velocity on the inclined plane is to its velocity in the perpendicular defcent, at the end of any given time.

Hence, 1. The fpace paffed over on the inclined plane is to the fpace it would defcend in the fame time in the perpendicular plane, as the altitude of the plane A B to its length A C; and, therefore, as the fine of the angle of inclination C, to the whole fine.

2. If, then, from the right angle B, a perpendicular be let fall to A C; A C : A B :: A B : A D. So that in the fame time wherein the body would fall perpendicularly from A to B; in an inclined plane it will defcend from A to D.

3. The fpace, therefore, of perpendicular defcent being given in the altitude of the plane A B; by letting fall a perpendicular from B to A C, we have the fpace A D to be paffed over in the fame time on the inclined plane.

4. In like manner, the fpace A D, paffed over on the inclined plane, being given, we have the fpace A B through which it would defcend perpendicularly in the fame time, by raifing a perpendicular at D meeting the altitude of the plane in B.

5. Hence in the circle C D E F, *fig.* 5, the body will defcend through all the planes A D, A E, A F, A C, in the fame time; *viz.* in that time wherein it would fall through the diameter A B, fuppofing that perpendicular to the horizontal plane L M: becaufe all the angles D, E, F, C, in the femicircle, are right angles.

VIII. The fpace A D, (*fig.* 4.) paffed over an inclined plane A C being given, to determine the fpace which would be paffed over in any other inclined plane in the fame time.

From the point D erect a perpendicular D B, meeting the altitude A B in B; then will A B be the fpace through which the body would fall perpendicularly in that time. Wherefore, if from B a perpendicular B E be let fall to the plane A F; A E will be the fpace in the inclined plane which the body will pafs over, in the fame time wherein it falls perpendicularly from A to B; and confequently A D will be the fpace in the other inclined plane A C, which it paffes through in the fame time.

Hence, fince A B is to A D as the whole fine to the fine of the angle of inclination C; and A B is to A E as the whole fine to the fine of the angle of inclination F; the fpaces A D and A E, which the body will pafs over in the fame time on different inclined planes, are as the fines of the angles of inclination C and F, and reciprocally as the refpective gravities on the fame planes. And, confequently, they are alfo reciprocally as the lengths of planes equally high, A C and A F. Whence the problem may be refolved various ways by calculation.

IX. The velocities acquired in the fame time on different inclined planes, are as the fpaces paffed over in the fame time.

For A D, A B, and A E, are the fpaces paffed over in the fame time; and fince A B : A C :: the velocity acquired in paffing over A D to the velocity acquired in paffing over A B; A C : A F :: the velocity acquired in paffing over A E to the velocity acquired in paffing over A B; A B : A C :: A D : A B; and A B : A F :: A E : A B; the velocity acquired in paffing over A D is to the velocity acquired in A B :: A D : A B, and the velocity acquired through A E to the velocity through A B :: A E : A B; therefore the velocities acquired in the fame time in paffing over A D and A E will be as the fpaces of A D and A E paffed through in the fame time.

Hence, alfo, they are as the fines of the angles of inclination C and F; reciprocally as the refpective gravities on the fame planes; and reciprocally as the lengths of equally high planes A C and A F.

X. A body defcending on an inclined plane A C, when it arrives at the horizontal line C B, has acquired the fame velocity which it would have acquired in a perpendicular defcent A B, to the fame horizontal line C B.

For A D is the fpace paffed over in the fame time with A B; and, therefore, the celerity acquired in paffing through A B is to that acquired through A D as A C to A B: but the celerity through A C is to that acquired through A D :: $\sqrt{A C} : \sqrt{A D}$; and fince A C : A B :: A B : A D, A C : A D :: $A C^2 : A B^2$, and $\sqrt{A C} : \sqrt{A D}$ :: A C : A B: confequently the celerity acquired through A C is to that acquired through A D as A C is to A B: therefore the celerity acquired through A C is equal to that acquired through A B.

Hence 1. A heavy body defcending through different inclined planes A C, A G, A F, hath acquired the fame velocity when it arrives at the fame horizontal line B F.

Hence alfo, 2. A body, continuing its defcent through feveral contiguous inclined planes, acquires the fame velocity which it would acquire in defcending perpendicularly to the fame horizontal plane.

XI. The time of defcent along an inclined plane A C, is to the time of perpendicular defcent through A B, as the length of the plane A C, to its altitude A B: but the times of defcent through different inclined planes equally high, A C and A G, are as the lengths of the planes.

For the time through A C is equal to the time in which A C would be defcribed uniformly with half the celerity acquired in C; and the time through A B is equal to that in which A B would be defcribed uniformly with half the celerity acquired in B; but thefe celerities are equal; confequently the times are as A C and A B. In the fame manner it might be fhewn, that the times of defcent through A C and A G, are as A C and A G.

XII. If the diameter of a circle A B (*fig.* 5.) be perpendicular to the horizontal line L M; a body will defcend from any point of the periphery D, E, or C, to B, along an inclined plane D B, E B, and C B, in the fame time in which it will defcend through the diameter A B.

For, letting fall the perpendicular C G, the time in which G B is defcribed is to the time in which B C is defcribed as B G : B C; but the time in which B C is defcribed is to the time in which A B is defcribed in the fubduplicate ratio of B G to A B; *i. e.* becaufe B G : B C :: B C : A B, in the ratio of B G to B C: confequently, the time of defcent through G B has the fame ratio to the time of defcent through B C and the diameter A B; therefore the time in which B C is defcribed is equal to the time in which A B is defcribed, &c. Hence,

XIII. The defcents of bodies through a femicycloid D E F (*fig.* 6.), and through any arc thereof D G, are always isochronal, or performed in the same time; on which principle is founded the doctrine of pendulums vibrating in a cycloid. See CYCLOID and PENDULUM.

The inclined plane is a mechanical power, often applied with advantage to practical purposes, and forms a very useful part of machinery in the elevation of great weights. It is supposed that in all the edifices of remote antiquity, where great masses of stone were employed, as in the pyramids of Egypt, and the druidical temples of this country, these vast blocks were elevated on inclined planes of earth, or of scaffolding, with the assistance also of levers and rollers. Inclined planes are frequently used for drawing boats out of one canal into another: and sometimes the local circumstances are such, that this may be done with great convenience, merely by allowing a loaded boat to descend, and to turn the axis which raises an empty one. An example of this may be seen, on a large scale, in the duke of Bridgewater's canal. This canal is extended, above ground, for forty miles on one level; an underground navigation, twelve miles long, joins it at Worsley, leading to the coal-mines under Walkden moor. At a height of $35\frac{1}{2}$ yards above this, is another subterraneous portion, nearly six miles in length. The connection between these levels is formed by an inclined plane: the boats are let down loaded, and proceed three miles along the tunnel into the open canal. The inclined plane is fixed in a stratum of stone, which fortunately has the most eligible inclination of 1 in 4, and is 33 yards in thickness, affording the most advantageous means of fixing every part of the machinery with perfect security. The whole length of the plane is 151 yards, besides a lock of 18 yards at the upper end.

Inclined planes are used in many places for raising and lowering coal-wagons, so that one is brought up by the force of that which descends. Inclined planes are also universally employed for facilitating the ascent of heights, by men or by animals; they may be either uniform, as roads, or the general inclination of the surface may be superseded by the formation of separate steps or stairs. The inclination of the surface may be governed by the proportion of the strength of the animal to its weight, the force required to support any weight on a plane being to the whole weight as the height of the plane to its length, and if the plane be a little less inclined than the exact equilibrium would require, the animal will be able to acquire a sufficient velocity at first to carry it easily up the ascent with a motion nearly equable. The strength of a labourer may be advantageously employed in ascending a given height by a flight of steps, and placing himself on a stage which may raise a weight by its descent; but it appears that the force of other animals is less calculated for exertions of this kind.

PLANES, *Laws of Ascent of Bodies on inclined.*—I. If a body ascend in a medium void of resistance, in any direction, whether perpendicular, or along an inclined plane; its motion will be uniformly retarded.

Hence, 1. A body ascending either perpendicularly or obliquely, in such a medium, passes over a space which is subduple of that it would pass over in the same time on an horizontal plane, with an uniform celerity equal to that it has at the beginning of its motion.

2. Such spaces, therefore, performed in equal times, decrease in a retrograde order, as the uneven numbers 7, 5, 3, 1; and therefore the ascent is so much impeded; and consequently, when the impressed force is exhausted, the body will descend again by the force of gravity.

3. They are, therefore, inversely as the spaces described in the same times by a body descending through the same altitude. For, suppose the time divided into four parts; in the first moment, the body A descends through the space 1, and B ascends through 7; in the second, A descends through 3, B ascends through 5, &c.

4. Hence a body, rising with an impressed force, ascends to that altitude, from which it must fall to acquire that velocity in falling with which it ascended.

5. Hence, by falling, it acquires a force to rise again to the height from which it fell.

II. The time in which a body ascends to a given altitude, being given; to determine the space passed over each moment.

Suppose the same body to descend from the same altitude in the same time; and find the spaces passed over each moment.

These, taken inversely, are the same with the spaces of ascent required.

Suppose, *v. gr.* a body projected perpendicularly, to ascend through a space of 240 feet in four seconds; and the spaces of ascent performed in the several times required; if now the body had descended, the descent in the first minute had been 15 feet, in the second 45, in the third 75, in the fourth 105, &c. The descent therefore will be in the first moment 105, in the second 75, &c.

III. If a body descend either perpendicularly through A D (*fig.* 6.), or in any other surface F E D, and with the velocity it has there acquired, again ascend along another surface D C, at points equally high, *e. gr.* at G, H, and Q, it will have the same force, and the same velocity.

Hence, if a body descend along any surface F E D, and again descend along another similar and equal surface D G C, it is the same as if it passed over the several parts of the same line twice.

Whence, the times of ascent and descent through equal spaces are equal.

On this principle are founded the construction and use of pendulums.

PLANE *of Gravity*, or *gravitation*, is a plane supposed to pass through the centre of gravity of the body, and in the direction of its tendency; that is, perpendicular to the horizon.

PLANE *of Reflection*, in *Catoptrics*, is a plane which passes through the point of reflection; and is perpendicular to the plane of the glass, or reflecting body.

PLANE *of Refraction* is a plane drawn through the incident and refracted ray.

PLANE *of the Horopter*, in *Optics*, is a plane that passes through the horopter A B (*Plate* VI. *Optics*, *fig.* 3.) and is perpendicular to a plane passing through the two optic axes I C and C H. See HOROPTER.

PLANE *of the Projection*, in the *Stereographic Projection of the Sphere*, is the same with the *perspective plane*; which see.

PLANE *of a Dial*, or *Dial-plane*, the surface whereon a dial is drawn. See DIAL.

We have horizontal, vertical, inclining, declining, reclining, deinclining, direct, oblique, &c. dial-planes. See DECLINER, RECLINER, DIRECT, &c.

PLANE, *Declination and Inclination of a.* See DECLINATION and INCLINATION.

For the method of finding both, see DECLINATOR.

PLANE *Glass*, *Mirror*, *Figure*, *Number*, *Problem*, &c. See PLAIN *Glass*, *Mirror*, *Number*, *Figure*, *Problem*, &c.

PLANE, *Geometrical*, in *Perspective*, is a plane parallel to the horizon, whereon the object to be delineated is supposed to be placed.

This plane is usually at right angles with the perspective plane. See PERSPECTIVE.

Plane, *Horizontal*, is a plane paffing through the fpectator's eye, parallel to the horizon, cutting the perfpective plane, when it is perpendicular to the geometrical one, at right angles.

Plane, *Objective*, is any plane fituate in the horizontal plane, whofe reprefentation in perfpective is required.

Plane, *Perfpective*, is a plain pellucid furface, ordinarily perpendicular to the horizon, and placed between the fpectator's eye and the object he views; through which the optic rays, emitted from the feveral points of the object, are fuppofed to pafs to the eye, and in their paffage to leave marks that reprefent them on the faid plane.

Some call it the *table*, or *picture*, becaufe the draught or perfpective, of the object, is fuppofed to be thereon; others the *fection*, from its cutting the vifual rays; and others the *glafs*, from its fuppofed tranfparency. See Perspective.

Plane, *Vertical*, a plane paffing through the fpectator's eye, perpendicular to the geometrical plane, and ufually at right angles to the perfpective plane. See Perspective.

Plane, a tool ufed by artificers who work in wood, to produce ftraight, flat, and even furfaces upon that material. Almoft all trades which fabricate articles of wood, employ planes at times; but as joiners make a greater ufe of thefe tools than any others, they are ufually confidered as joiners' and carpenters' tools. Planes have been, of late years, ufed by fome artifts to produce flat furfaces in metals. A plane operates to cut off a thin chip or fhaving from the wood on which it is applied, by the fharp edge of a fteel cutter or broad chiffel, called, very improperly, the plane *iron:* this is fixed in a hole made through a wooden block, called the plane *ftock*, and the edge of the iron projects a very fmall quantity through the lower fide of the ftock, called the *face* of the plane; the furface of which face is made a perfectly true plane. The iron is fixed in an inclined pofition in the hole through the ftock, by means of a *wedge* driven in before it, to jamb it faft in the hole, which being wider than the thicknefs of the iron, leaves an aperture before the iron, called the *mouth* of the plane: this is very narrow where it opens in the lower fide or face, but grows wider as it rifes up through the ftock; the wedge is alfo cut forked, to allow more room for the fhavings which the plane iron cuts to pafs up before it through the mouth. When a plane of this kind is applied with its face upon the furface of a piece of wood, and preffed down upon it whilft it is moved forwards, the edge of the iron penetrates the wood to the depth which it projects through the face, and removes a fhaving of that thicknefs and the whole breadth of the edge of the iron, the fhaving turning up before the iron paffes through the mouth, and efcaping. The inclination of the iron makes it cut eafily; and if the iron is *fet fine*, that is, if the edge projects but very little beyond the face, it will remove very thin fhavings, and produce a flat and fmooth furface: on the other hand, if it is *fet rank*, that is, with a confiderable projection, it will cut away very faft, producing a flat though rough furface, and quickly reducing the wood to its intended thicknefs: if the wood has an irregular furface, it foon reduces it to a plane, becaufe the face, being flat, will not fuffer the edge of the iron to defcend into the hollow places, but removing all the eminences it paffes over till they are reduced to one level.

This is a general defcription of feveral kinds of planes, which are all known by different names, from their different dimenfions and purpofes. Joiners ufe the *jack plane*, the *long plane*, *trying plane*, *fhooting plane* or *jointer*, and the *fmoothing plane;* all which they denominate *bench planes*, becaufe the wood they are ufed upon is generally laid on the work-bench. They have alfo the *ftraight block* for ftraightening fhort edges, *rebating planes* for forming rebates; others, for the fame ufe, are called the *moving fillifter*, *fafh fillifter*, and *fide-rebating plane*. The *plough* is a narrow plane, provided with apparatus to guide it, in moving ftraight, to plow a groove or trench at any required diftance from the edge of a board or other piece of wood, and to any depth or width. The *dado grooving plane* is alfo for forming grooves.

There are feveral other tools, which, having an iron fitted into a ftock, are called planes, becaufe they cut in the fame manner, though, in ftrictnefs, they are not planes, for they do not make plane furfaces; thefe are *moulding planes*, with faces and cutting edges curved, to produce all the varieties of ornamental mouldings, and which are known by the names of *fnipe's-bills; fide fnipe's-bills*, *beads*, *hollows* and *rounds*, *ovolos* and *ogees*. The varieties and different fizes of thefe form a vaft number, with which every complete joiner is furnifhed. It is impoffible to defcribe the terms applied to thefe tools without figures, as they are arbitrary, though generally known among workmen. The faces of all thefe planes are ftraight in the direction of their length, but a fection acrofs the face is the impreffion or reverfe of the moulding they are intended to make, and the edge of the iron is curved to correfpond with this curve when in its place, but will in reality be a very different figure, becaufe it is inclined to the face of the plane at an angle of about forty-five degrees. Another diftinction between thefe and the bench planes is, that their mouths do not open fo as to difcharge the fhaving through the ftock at the top thereof, but the wedge completely fills the hole, and the fhaving paffes out fideways through a hole for that purpofe; in fome, thefe apertures are on the right, and in others on the left fide; in the firft cafe the fhaving is faid by the workmen to be thrown on the bench, that is, upon the right fide of the plane; but when the orifice of difcharge is on the left, and confequently the fhaving thrown upon the left, then the plane is faid to throw the fhaving off the bench. The *compafs plane* is ufed by coach makers, cabinet makers, &c.; it is made with a convex face, formed to an arc of a circle in the direction of its length, and it therefore forms the concave furface of a cylinder. The *forkftaff plane* is ftraight in the direction of its length, but its face is made concave in its breadth, to the arc of a fmall cylinder; the edge of the iron is of courfe curved in the fame manner, and it planes cylindrical furfaces. Coopers alfo employ long and heavy planes to form the edges of the ftaves of barrels; thefe are mounted in an inclined pofition on legs like a ftool, with their faces upwards, and the ftave is drawn backwards and forwards upon them.

Planes are fo neceffary for all kinds of work, that any who intend to work in wood, fhould underftand the ftructure and the manner of ufing them. The *jack plane* is ufed for taking off the rough and prominent parts from the furface of the wood, and reducing it nearly to the intended thicknefs, in coarfe fhavings or flices. The ftock of this plane is about feventeen inches in length, three inches high, and three and a half inches broad; all the fides are ftraight and at right angles to each other: the mouth is cut through the folid of the ftock to receive the iron, and hold it at fuch an elevation, as to make an angle of forty-five degrees with the face of the plane; the iron is a thin metal plate, one fide confifting of iron the other of fteel; the lower end of the iron is ground to an acute angle off the iron fide, forming a floping part called the bafil of the iron, fo as to bring the fteel fide to a fharp edge: the wedge which fixes the iron in its place, is let

let into two grooves of the fame form, on the fides of the opening or mouth: two fides of the wedge are parallel, and it is forked or cut away in the middle, leaving the fides like two prongs, to fill the lower part of thefe grooves; this allows the fhaving to pafs up without obftruction before the wedge: for the mouth or opening through the ftock muft be uninterrupted from the face to the top, and muft be no wider on the face of the plane, than is fufficient for the thickeft fhaving to pafs with eafe; and as the fhaving is difcharged at the upper fide of the plane, the opening through it muft expand or increafe from the face to the top, fo as to prevent the fhavings from fticking therein. A handle, called the *tote*, is fixed to the upper fide of the ftock, immediately behind the iron; it is formed to the fhape of the hand, and direction of the motion, fo as to produce the moft power in pufhing the plane forward.

A workman in ufing the jack plane, lays the piece of wood on the *bench* parallel to its fides, with the farther end lodged againft the *bench-hook;* then laying the fore-part of the plane upon the hind end of the wood, with the right hand he takes the handle, and preffing with his left upon the fore end, thrufts the plane forward in the direction of the fibre of the wood and length of the plane, until he has extended the ftroke the whole length of his arm, the fhaving being difcharged at the orifice; he then draws back the plane, and repeats the operation in the next adjacent rough part, proceeding in this manner until he has removed the rough parts throughout the whole breadth. He then fteps forwards the diftance of the length he has planed, and operates upon another length in the fame manner, proceeding this way by fteps, until the whole length is gone over and rough planed. To do this is very eafy; but a workman will not make good progrefs nor do clean work, unlefs he has firft adjufted his tool properly for the work. The methods of doing this are nearly the fame for all planes. The firft care is to obtain a fharp cutting edge to the iron; if it requires grinding on the grindftone, the carpenter places his two thumbs under the iron, and the fingers of both hands above, laying the bafil fide to the grindftone, and holding it to the angle he intends it fhall make with the fteel fide of it, keeping it fteady while the ftone revolves; and preffing the iron to the ftone with his fingers; in order to prevent the ftone from wearing the edge of the iron into irregularities, he moves it alternately from edge to edge of the ftone, with fo much preffure on the different parts as will reduce it to the required bevel, and make the edge ftraight.

The bafil being brought to a proper angle, and the edge to a regular and flight curvature, the roughnefs occafioned by the gritty particles of the ftone are taken away by rubbing its edge on a fmooth flat hone or Turkey ftone, fprinkled with olive oil on its furface. As the bafil is generally ground, to give a more acute angle than the edge of the iron would ftand, for the quicker difpatch of wetting it, the face of the iron is inclined nearer to the perpendicular, while it is rubbed backwards and forwards with the fame inclination throughout. Every time the iron becomes dull or blunt by ufe, the fharpening is produced by grinding on the rubber-ftone, or flat grindftone, or on a Turkey ftone; but in repeating this, after the edge gets thick, it requires fo much time to bring it up to an edge, that recourfe muft be had to the grindftone. The iron being thus fharpened, muft be fixed in the plane by its wedge: the projection of the cutting-edge muft be juft fo much beyond the face of the plane, as that the workman may be able to work it freely in the act of planing, and muft be regulated by the ftuff to be wrought; whether it is hard or foft, crofs-grained or curling; fo that a man may be able to perform the moft work, or reduce the fubftance moft in a given time. If the ftuff is good and clean-grained, it is evident that a confiderable projection may be allowed, as a thicker fhaving may be taken: the extreme ends of the edge of the iron muft never enter the wood, as this not only retards the progrefs of working, but choaks and prevents the regular difcharge of the fhavings at the orifice of the plane. The projection of the cutting-edge is called *iron*, and the plane is faid to have more or lefs iron, as the projection is greater; when there is too much iron he knocks with a hammer on the fore end of the top of the ftock, and the blows will loofen the wedge, and raife the iron in a certain degree, and the head of the wedge muft be knocked down to fix it again.

When he has occafion to take out the iron to fharpen it, he ftrikes the fore end of the top of the ftock fmartly with the hammer, which loofens the wedge and the iron.

All the other bench planes are adjufted in the fame manner, and indeed do not differ, except in dimenfions, as we fhall explain, from the jack plane. Of late years, a great improvement has been introduced in the irons of planes, to caufe them to cut fmooth; thefe are called double ironed: they were at firft only ufed in the fineft fhooting planes, but the advantages have been found fo great, particularly in planing bad wood, that they have become general for all forts of planes. The double iron confifts of a fecond iron, with a reverfed bafil fcrewed againft the front fide of the iron, fo that its edge lies againft the iron at a very fmall diftance from, and parallel to, the cutting edge; and applying clofely to the fteel fide of the iron, it forms an inclined plane, which turns the fhaving over immediately after it is feparated or cut up by the edge, and thus it prevents the iron from fplitting the fhaving deeper down than it will afterwards cut, and therefore leaving a rough or torn furface. This fecond iron is called the cover of the iron; and the bafil of its edge, inftead of being ground flat, as that of the iron, is rounding: the fcrew, which binds the cover upon the iron, paffes through a flit in the cover, and thus admits of its edge being adjufted at any required diftance from the cutting edges of the iron, and this diftance depends altogether on the nature of the wood the plane is to be worked upon. If the ftuff is clean-grained, the edge of the cover may be fet at a confiderable diftance, becaufe the difficulty of pufhing the plane forwards becomes greater, as the edge of the cover is nearer the edge of the iron, and the contrary when more remote: this is occafioned by the edge of the cover turning the fhaving over immediately it is cut up.

The *trying plane* is ufually twenty-two inches long, three-quarters broad on the face, and three in height; it does not differ from the jack plane, except in having a double handle, adapted for greater force: in ufe, it fucceeds the operation of the jack plane, to ftraighten the wood, and remove the ridges left by the former; it is fet with lefs iron, and cuts a finer fhaving: the mouth is alfo much narrower. When it is ufed upon a long piece of work, the workman takes every fhaving the whole length, by ftepping forwards, inftead of ftopping at arm's length, as with the jack plane. The fhaving of this plane, though finer, is fo much broader than the jack, that it requires as much force to pufh it forwards.

The *long plane* is fet very fine for finifhing work which is to be very ftraight; it is twenty-fix inches long, three and a half broad, and three inches in height.

The *fhooting plane*, or *jointer*, is the longeft, and moft correct plane ufed; it is employed after all the others, chiefly in fhooting the ftraight edges of boards which are to be jointed together; it is generally made two feet and a half long,

long, three inches and a quarter broad, and three and a half high; it is ufed like the others, but with great care to move it fteadily from one end of the work to the other, without preffing it down, as that might fpring the plane, or the work, and caufe the iron to cut when the work was fomething hollow, whereas the object is to make a perfectly ftraight edge. The face of this plane muft be kept quite true, and therefore it is a great object to make it of a fine piece of clean-grained, hard beech, well feafoned, that it may not warp, or vary, by the weather.

The *fmoothing plane* is very fhort, without any handle, and its fides are curved, fo that it very much refembles a coffin; it is feven inches and a half long, three broad at the mouth, and two inches and three quarters in height; it is ufed for finifhing work when put together, and to give the greateft degree of fmoothnefs to the wood, for which purpofe it is fet with as fine an edge as poffible.

Rebating planes are ufed for cutting out rebates; thefe are a kind of femi-grooves upon the edge of a board, or other piece of wood, formed by cutting down or reducing a fmall part of the breadth of the board to half, more or lefs, of the general thicknefs: by this means, if a rebate is cut on the upper fide of one board, and the lower fide of another, the two may be made to overlap each other, without making them any thicker at the joint. Rebates are alfo ufed for ornamenting mouldings, and many other purpofes in joiners' work. The planes for cutting them are of different kinds, fome having the cutting edge at the fide of the iron and of the ftock, others at the bottom edge of the iron and the face of the ftock, and others cutting in both thefe directions; the former, being ufed to fmooth the fide of the rebate, are therefore called fide-rebating planes; whilft the others are ufed for fmoothing the bottom. There is alfo a third fort, called *fillifters*, ufed for finking, or cutting away the edge of the piece of wood to form the rebate, leaving it for the others to fmooth the furfaces when cut. The rebate planes are about nine inches and a half long, and of various widths upon the face, from half an inch to an inch and three quarters; in all cafes they have the mouth and the edge of the iron coming out at one edge of the face, and the fide of the iron alfo expofed at one of the upright fides of the ftock, whether it is formed with a cutting edge there or not: this expofed fide is either on the right or left, and they are named accordingly. In all cafes they throw the fhaving out on the fide, inftead of at the top of the ftock. The cutting edges and mouths are generally fituated obliquely acrofs the face, inftead of being at right angles to the length of the plane, as in others.

The *moving fillifter* is a rebating plane, which has a ruler of wood, called the *fence*, fixed upon its face by fcrews in the direction of its length, and exactly parallel to the edge of the face; it therefore covers part of the length of the cutting edge, and can be fixed at any required diftance from the edge, to leave more or lefs of the cutting edge expofed, and this quantity will be the breadth of the rebate it will cut; becaufe when it is ufed, the edge of the fence is applied againft the edge of the piece to be rebated, and thus gauges the breadth its iron fhall cut away. The cutting edge of this plane is not fituated at right angles to the length of the ftock, but has an obliquity of about forty-five degrees, the expofed fide of the iron being more forwards than the other. By this obliquity, when the plane is worked, it has a tendency or drift to run farther into the breadth of the wood, but as the fence, fliding againft the edge, prevents this, the drift always keeps the fence in contact with the edge, without the attention of the workmen; it alfo caufes the iron to cut the bottom of the rebate fmoother, particularly in a tranfverfe direction to the fibres, or where the ftuff is crofs-grained, than could otherwife be done, when the fteel face of the iron is perpendicular to the vertical fides of the plane. The principal ufe is, however, to contribute, with the form of the cavity, to throw the fhaving into a cylindrical form, and thereby making it iffue from one fide of the plane. The iron is what is called fhouldered, that is, the lower part or fhoulder where the edge is, has double the width of the upper part, which is received into the mortife, and jambed faft by the wedge. It is the edge of this wide part only which is expofed at the fide of the ftock. Befides this principal iron, there is another fmall iron, called the tooth, which precedes the other, to fcratch or cut a deep crack at the width of the rebate, thus making the fhavings which the iron cuts up from the bottom feparate fideways from the reft of the wood. This tooth is inferted in a vertical mortife through the ftock, between the fore end of the ftock and the iron. The lower end of this little iron is ground with a bafil on the infide, fo as to bring the bottom of the narrow fide of the iron to a very convex edge; it is faftened by a wedge paffing down before it in the mortife in the ftock. The ufe of this tooth is principally for cutting the wood tranfverfely when wrought acrofs the fibres, and by this means it not only cuts the vertical fide of the rebate quite fmooth, but prevents the iron from ragging or tearing the ftuff. The iron between the fence and the edge of the face of the plane, muft project the whole breadth of the uncovered part of the face, otherwife the wood of the plane will bear it up, and prevent the plane finking as it cuts away the rebate, and the edge of the tooth or little iron fhould ftand out a little farther on the fide of the plane than the iron. The depth of the rebate which this plane will cut, is regulated by a ftop fixed on the outfide of the plane, at the intended height above the level of the face: then, when the plane has penetrated or funk the intended depth of the rebate, the ftop comes to bear upon the folid of the wood beyond the rebate, and bears it off from cutting any longer. The ftop is a piece of brafs, which moves in a vertical groove made in the fide of the ftock, between the iron and the fore end of the plane; in this it is moved up and down by a fcrew, which is inferted in a vertical perforation from the top of the plane to the groove, and paffing through a part projecting from the ftop into the groove: the upper part of the fcrew is formed to a thumb-nut, to turn it round by, and it is fo confined by proper collars, that it can neither move up nor down; but being turned, the inclination of the threads will rife or fall according to the direction in which the thumb-fcrew is turned, and caufe the ftop to move up and down in the groove on the fide of the plane, thus regulating it at pleafure to the depth to which the rebate is required to be funk.

In grinding and fixing the iron of this plane, it is neceffary that the cutting edge of the iron fhould ftand equally prominent in all parts out of the face, otherwife the plane cannot make fhavings of an equal thicknefs; and, confequently, inftead of keeping the vertical pofition, will, as it proceeds, become deeper on the fide on which the fhavings are thickeft, and then the part cut away will not be regular, for the bottom of the rebate will not be parallel to the upper furface of the wood, and the fide which ought to have been vertical, will be a kind of a ragged curved furface, formed by as many gradations or fteps in the depth as the number of fhavings.

The *fafh fillifter* differs in feveral particulars from the moving

ing fillister: the breadth of the iron is something more than the whole breadth of the sole, so that the extremities of the cutting edge are in a small degree without the vertical sides of the stock: the fence is adapted to be moved to a considerable distance, not being fixed, as in the moving fillister, by screws upon the face, but sustained by two bars fixed fast to it, which pass through the two vertical sides of the stock, at right angles to the sides, fitting tight in the two holes through which they pass; these bars are made rounding upon the upper side and flat on the lower side: at the point where they are united to the fence, they have thicker parts, or shoulders, projecting downwards, because it is necessary to have the fence fixed on a lower level than the face of the plane: the ends of the bars are ferruled, to prevent splitting when the ends are struck with a mallet, in order to move them in the holes through the stock, and this brings the fence either nearer or more remote from the stock, as may be wanted; and to fix it fast, when so adjusted, two small tapering pieces of wood, called keys, are inserted into two small wedge-like mortises, cut at the sides of the mortises in which the bars pass through the stem; these wedges being drawn in, they will stick fast, and press against the bars, keeping them fast at all points, and thereby regulate the distance of the fence from the vertical side of the stock. This plane is generally employed to rebate narrow pieces of wood, such as sash frames; and the fence is applied against the opposite edge of the wood to that on which the rebate is to be formed.

The *plough* is a plane with a very narrow face, made of iron, fixed beneath a wooden stock, and projecting down from the wood of the stock, the edge of the iron being the full width, or rather more, than the face; it is guided by a fence with two bars, like the fillister above described, to make or plough out a groove of the width of the iron, and at any required distance from the edge of the wood; it has also a similar stop to regulate the depth it cuts to.

Plane for planing surfaces of Metal.—This tool has been brought into use within these few years past, to the great improvement of the work of those artists who employ it. These are chiefly the mathematical instrument-makers who are in the constant habit of having to make straight rulers in brass, and prepare work requiring very flat surfaces, such as the limbs of sextants, &c.; but all trades which work in brass and iron, would find their advantage in employing the plane. The stock of this plane is usually made of cast-iron, in form of a hollow box, the bottom, sides, and ends being all cast in one piece; it is usually 12 inches in length, $1\frac{3}{4}$ in height, and $1\frac{1}{2}$ in breadth across the face; the iron is situated at about four inches from the fore end, not inclined, as in other planes, but held in a perpendicular direction, with its lower or cutting edge passing through the mouth, and projecting the least possible quantity beneath the surface of the face, but leaving only so small a space before the edge for a mouth, as will but just admit a piece of thick paper; the iron is held against a brass frame fixed across in the hollow of the box or plane, and containing within it a screw, on which a nut or slider is fitted, to rise and fall when the screw is turned round by a milled head upon the upper end of it; the nut or slider has a projecting pin, which enters into a round hole made through the iron; and in this case, by turning the screw, the iron is raised or depressed, to cause the edge to protrude more or less beyond the face; to support this frame behind, a block of wood is fitted into the hollow of the stock, to fill up all the cavity, and it projects so much above as to form the handle for the plane.

In the front end of the stock a screw is tapped through its thickness, and acts against a piece of wood, which it presses up against the iron, and thus holds it fast against the brass frame, in the same manner as the wedge of a common plane; this piece of wood is formed forked and hollowed where it applies to the iron, to allow room for the chips to come up from the mouth. The workmen who use this plane call it *striping*, instead of planing, brass or other metal.

The metal plane is used in the same manner as a carpenter's jack plane, but as the shaving it cuts, or rather scrapes off, must be exceedingly thin, the greatest nicety is necessary in adjusting the projection of the iron beyond the face; and for this reason the screw is essential.

The work is to be supported upon a firm bench, which is best made of cast-iron, and the surface of it made perfectly flat, which is done by grinding the face of the plane against it with emery, till both are true. The front face of the iron is quite flat, and perpendicular to the face; the edge is formed at the bottom of this surface by grinding a bevel from the back at an angle of about 45 degrees; the edge is then made fine by a Turkey stone. The iron must be exceedingly hard and of the very best steel, and then the plane will cut soft steel, bell-metal, or *cast-iron*, as well as brass, to very good purpose. When the work is rough, it is difficult for a man to work the plane, if set coarse for expedition, they therefore use, in such case, an iron which is cut with flutes on the front side, and then the edge will be divided into separate teeth, which scrape and cut away with less resistance than a complete edge. Messrs. Holtzapfell and Deyerlien of Cockspur-street, make these planes for metal of exceedingly hard cast-iron, and very true faces, which do not therefore become scratched or injured by wear. It should have been mentioned before, that joiners, cabinet-makers, &c. in planing thin or valuable woods for veneering, &c. sometimes use fluted irons, having teeth in their edge; and a plane thus mounted is called a *toothing plane;* these irons apply to the stocks of different planes.

Plane, among *Fowlers*. To plane, is to fly or hover, as a kite or other bird does, without moving its wings.

Plane, in *Geography*, a town of America, in Stark county, and state of Ohio, containing 527 inhabitants.

Plane-*Tree*, in *Botany*. See Plantanus.

Plane-*Tree*, *Bastard* or *False*. See Maple.

Plane-*Tree*, in *Planting*, the common name of an elegant tall growing tree of the timber kind, of which there are two species, as the Asiatic, or oriental, and occidental, or American; the first of which rises to a very great height, and in its native soil grows to a prodigious size; the stem is covered with a smooth bark, which falls off annually. The bark of the young branches is of a dark brown, inclining to a purple. The leaves are large and palmated, being deeply cut into five segments: their upper sides are of a deep green, and the under sides pale. The flowers are very minute: they come out at the same time as the leaves, which is in June. This, Mr. Marshall says, is very late, and is, no doubt, a blemish to the beauty of this nevertheless highly ornamental tree. The ancients were very partial to this tree; which is not to be wondered at, when the extensive canopy it forms is considered, the impenetrable shade given by the number and size of the leaves, and consequently the grateful coolness it must afford in a sultry climate. This, as well as the American sort, has been considered as a forest or timber tree; and their wood may rank with that of the sycamore, which bears a considerable resemblance to them, and which, in the north of England, is often improperly called the plane-tree.

With regard to the second sort, or American plane, it grows to a great size; the stem not only swells to an immense thickness but, rising erect, shoots up perfectly straight

ſtraight and cylindrical to an amazing height. The bark is ſmooth, and, like that of the Aſiatic or former ſort, falls off annually. The leaves are broad, with long footſtalks, and are cut into angles at their edges, but not divided nearly ſo deep as thoſe of the other kind. The upper ſide is of a light green, the under ſide paler. The flowers are ſmall, and come out with the leaves about the ſame time as thoſe of the Oriental plane. Mr. Marſhall thinks that, on the whole, this tree is peculiarly refreſhing to the eye, and truly ornamental.

And in addition to theſe ſpecies, there are two varieties of the firſt ſort, as the maple-leaved plane, and the Spaniſh plane, the firſt of which differs from the other ſorts, in having its leaves not ſo deeply cut as thoſe of the Eaſtern plane, but much more deeply than thoſe of the occidental. The footſtalks of the leaves are much larger than thoſe of either of them, and the upper ſurface of the leaves is rougher. They might, of courſe, be taken for different ſpecies, if it was not well known that they are produced from the ſame ſeeds. The Spaniſh plane has larger leaves than either of the other ſorts. They are divided in a ſimilar manner to thoſe of the maple-leaved plane. Some of them are cut into five, and others into three lobes: theſe are ſharply indented on their edges, and are of a light green. It is by ſome called the middle plane, from its leaves being ſhaped between thoſe of the firſt two ſorts.

The firſt of theſe ſorts may be raiſed from ſeeds, where they can be procured; but in other caſes recourſe muſt be had to layers. And the ground proper for raiſing them in, is ſuch as is moiſt and ſhady, well dug, and raked until the mould is fine; then in the autumn, ſoon after the ſeeds are ripe, they ſhould be ſcattered over the ſurface, and be raked in the ſame manner as turnip ſeed. In the ſpring, many of the young plants will appear, but it muſt not be expected that the general crop will come up until the ſecond year; the ſpring after which they may be taken out of the ſeed-bed, and planted in a nurſery-ground in rows one yard aſunder, and at one foot and a half diſtance in the rows. Here they ſhould remain, with the uſual care of digging between the rows, and keeping them clean, till they are of ſufficient ſize to be planted out in plantations or other places, either as timber or ornamental trees. In the layering method a ſufficient number of trees muſt be planted out for ſtools, on a ſpot of earth double dug. After they have ſtood one year, they ſhould be cut down, in order to make them throw out young wood for layering. The autumn following, theſe ſhould be laid in the ground, with a little nick at the joint; and by the ſame time twelve months they will be trees of a yard high, with a good root, ready to be planted out in the nurſery, where they may be managed as the ſeedlings; and as the ſtools will have ſhot up freſh young ſhoots for a ſecond operation, this management may be continued as the planter may think fit.

But the American plane is moſtly raiſed by cuttings; which, if they be taken from ſtrong young wood, and planted early in the autumn, in a moiſt good mould, will hardly fail of ſucceeding. They are generally planted thick, and then removed into the nurſery-ground, as the layers of the other ſort: but if a large piece of ground was ready, Mr. Marſhall thinks theſe might be placed at ſuch a diſtance as not to approach too cloſe before they were of a ſufficient ſize to be planted out to ſtand; and this would ſave the expence and trouble of a removal. The Oriental plane-tree will alſo grow from cuttings, but not ſo certainly as this; and whoever has not the convenience of proper ground for the cuttings, muſt have recourſe to layers, which, indeed, for either ſort is the moſt effectual and certain method of proceeding.

Theſe ſorts of trees delight in a moiſt ſituation, eſpecially the occidental ſort. Where the land is inclined to be dry, the others are to be preferred. But in moiſt places, by the ſides of rivulets, ponds, &c. the occidental makes ſuch ſurpriſing progreſs, that it might be ranked among the aquatics. The bright colour of the plane-trees gives variety to groves and maſſes of wood; in groups and ſingle trees they are ſingularly elegant; as may be ſeen in many parks and other places. In ſuch ſituations and ſoils they may likewiſe be planted as timber trees with great advantage, as the wood is uſeful for a variety of purpoſes.

And the proper ſeaſon for planting out this ſort of trees is in the early ſpring, as about March; but they may be ſet out in the autumn, where the ſoil is not of too wet a nature, with perfect ſucceſs, though the other is always to be preferred if poſſible.

PLANERA, in *Botany*, ſo named by profeſſor Gmelin of Gottingen, the very incompetent editor of the Linnæan Syſtema Naturæ, at leaſt as far as the vegetable kingdom is concerned. He appears to have deſigned to commemorate James Planer, who publiſhed an Index of the plants about Erfurt, where he was profeſſor of medicine. Gmelin took his ideas of the genus from Walter's Flora Caroliniana, 230, it being one of thoſe which that writer had deſcribed as new, but which he had declined naming. Michaux has adopted *Planera*, Fl. Boreal-Amer. v. 2. 247, as has Mr. Purſh in his Fl. Amer. Septentr. v. 1. 115. Both remark its very near affinity to *Ulmus*. Indeed Michaux's deſcription hardly indicates any difference, except the flowers being polygamous, which is of no generic importance whatever. Michaux defines two ſpecies; *P. Gmelini*, a native of North America, *Anonymos aquatica* of Walter; and *P. Richardi*, a native of the country near the Caſpian ſea. This latter has long been known in the gardens of France and England, by the name of the Siberian Elm, or *Ulmus polygama*. *Ulmus nemoralis* of both editions of Hort. Kew. always appeared to us the ſame thing, but Mr. Purſh has the latter as a native American *Ulmus*, though Michaux has not any ſpecies under that name, nor does he give his *Planera Richardi* as an American plant. Pallas has figured the Caſpian tree, under the appellation of *Rhamnus carpinifolius*, Fl. Roſſ. v. 1. t. 60, but he had not ſeen the ripe fruit. Whatever this Caſpian plant may be, the *Abelicea cretica* of Pona, Cluſ. Hiſt. v. 2. 302, is certainly another ſpecies of the ſame genus, as has been ſhewn by the writer of the preſent article, in a paper on the ſubject of that little known plant, printed in Tr. of the Linn. Soc. v. 9. 126. Whether the genus in queſtion be diſtinct from *Ulmus*, appears very doubtful; but if it ſhould ſo prove, the name of *Planera* muſt give way to *Abelicea*, as a Greek name, publiſhed long ſince, and of good authority. See ULMUS, where poſſibly we may be able to throw ſome further light on this ſubject.

PLANET, PLANETA, πλανητης, *wanderer*, in oppoſition to a *ſtar*, which remains fixed, in *Aſtronomy*, a celeſtial body revolving round the ſun as a centre, and continually changing its poſition with reſpect to the other ſtars.

The planets are uſually diſtinguiſhed into *primary* and *ſecondary*.

PLANETS, *Primary*, called alſo ſimply, and by way of eminence, *planets*, are thoſe which move round the ſun as their proper centre. Such are the Georgian, Georgium Sidus or Herſchel, Saturn, Jupiter, Veſta, Juno, Pallas, Ceres, Mars, the Earth, Venus, and Mercury.

PLANETS,

Planets, *Secondary*, are such as move round some primary planet as their respective centre, in the same manner as the primary planets do round the sun. Georgium Sidus, Saturn, Jupiter, and the Earth, are each attended with secondary planets; the Georgian with six, Jupiter with four, and Saturn with seven, called the *satellites* of those planets. The Earth has one secondary planet, called the *Moon;* which see.

The motion of the primary planets is very simple and uniform, as being compounded only of a projectile motion, forward in a right line, which is a tangent to the orbit; and a gravitation towards the sun at the centre. (See Gravity.) Besides, as they are at such vast distances from one another, the effects of their mutual gravitation are in a considerable degree, though not altogether, insensible; for the action of Jupiter on Saturn, *e. gr.* is found to be $\frac{1}{217}$ of the action of the sun upon Saturn, by comparing the matter of Jupiter with that of the sun, and the square of the distance of the sun from Saturn, with the square of the distance of Jupiter from Saturn; so that the elliptic orbit of Saturn will be found to be more just, if we suppose its focus not to be in the centre of the sun, but in the centre of gravity of the sun and Jupiter, or rather, in the centre of gravity of the sun, and of all the planets below Saturn. In the same manner, the elliptic orbit of any other planet will be found more accurate, by supposing its focus to be in the centre of gravity of the sun, and of all the planets that are below it. But the matter is far otherwise in respect of the secondary planets; for every one of these, though it chiefly gravitate towards its respective primary one, as towards its centre, yet at equal distances from the sun, it is also attracted towards him with an equally accelerated gravity, as the primary one is toward him; but at a greater distance with less, and at a nearer distance with greater: from which double tendency towards the sun, and towards their own primary planets, the motion of the satellites, or secondary planets, comes to be very much compounded, and affected with many inequalities: as, for instance,

1. The satellite shall be continually accelerated in its motion, from the time of its quadrature with the sun to the next following conjunction or opposition; but contrarywise from the syzygies to the quadratures, it shall be retarded; and therefore it will always move swifter in or near the syzygies, and slower near the quadratures. From whence will follow that,

2. The orbits of these secondary planets will be of a figure more circular in the quadratures than in the syzygies, where the swiftness of the motion will make the figure of the orbit more rectilinear, and therefore the satellite will run farther from its primary planet at the quadratures than at the syzygies; so that the orbit will be a little elliptical, having the primary planet for its centre, and the longer diameter will coincide with the line of the quadratures, and the shorter with that of the syzygies. Which irregularities will arise, if the sun's power of disturbing the motion of the satellite be excluded, and the orbit be concentric with that of the primary planets: for if the orbit be excentrical, it may happen that the satellite shall be farther off from the primary one in the syzygies, and so move slower than it does at the quadratures; and when this is the case, that the satellite's orbit is not a circle concentric to the primary orbit, but an ellipsis, in one of whose focuses the primary planet is placed, then the motion of the satellite will be so disturbed by the sun, that, as it proceeds in its orbit, the apsides of the orbit will be moved sometimes *in consequentia*, and sometimes *in antecedentia* (whereas the nodes and apsides of the primary planets may be considered as at rest.)

3. When the plane of the satellite's orbit is inclined to the plane of the primary orbit, the line of the nodes of the secondary orbit will be moved *in antecedentia*, with an angular motion, and an unequal velocity; for it will recede most swiftly when the nodes are in quadrature to the sun; after which it will move slower; and at the time of the nodes being in the syzygies, it will be perfectly at rest.

4. The inclination also of the plane of the secondary orbit, to the primary one, will be continually varying, and will be greatest when the nodes are in the syzygies with the sun, and less, *cæteris paribus*, when they are in the quadratures; and from the time of the nodes being in the syzygies to the quadratures, it will be always decreasing, and from the time of their being in the quadratures to the syzygies, it will be always increasing; and all these irregularities, whether in any excentric or concentric orbit, will always be something greater, when the satellite is in conjunction with the sun, than when he is in opposition to him. See Moon and Satellites.

The primary planets are in number eleven, (including the earth) ten of which are again distinguished into the *superior* and *inferior*.

Planets, *Superior*, are those farther from the sun than our earth is. Such are Mars, Vesta, Juno, Pallas, Ceres, Jupiter, Saturn, and the Georgian.

Planets, *Inferior*, are those nearer the sun than our earth, and situate between the earth and sun. Such are Venus and Mercury. See the order, position, &c. of the planets, under *Copernican* System.

The planets are represented by the same characters as the chemists use to represent their metals by, on account of some supposed analogy between those celestial and subterraneous bodies.

The Georgian is represented by the character ♅, and performs its sidereal revolution in about 84 years.

According to La Place, the first five satellites of this planet may be retained in their orbit by the action of its equator, and the sixth by the action of the interior satellites; and hence he concludes, that this planet revolves about an axis very little inclined to the ecliptic, and that the time of its diurnal rotation cannot be much less than that of Jupiter or Saturn. When the Earth is in its perihelion, and the Georgium Sidus in its aphelion, the latter becomes stationary, when his elongation or distance from the sun is $8^s\ 17^\circ\ 37'$, and his retrogradations continue $151^d\ 12^h$. When the Earth is in its aphelion, and the Georgium Sidus in its perihelion, it becomes stationary at an elongation of $8^s\ 16^\circ\ 27'$, and the retrogradations continue $149^d\ 18^h$. The following table contains the most correct elements of the orbit of the Georgium Sidus, and other particulars relating to this planet.

Tropical revolution - -	$30589^d\ 8^h\ 27'$
Mean distance from the Sun, that of the Earth being 100000 - -	1908352
Density, that of water being 1 -	$0\frac{99}{100}$
Quantity of matter, that of the Earth being 1	16.84
Diameter in English miles -	35112
Inclination of its orbit in 1780 -	$46'\ 20''$
Place of aphelion in 1800 -	$11^s\ 16^\circ\ 30'\ 31''$
Secular motion of aphelion -	0 1 29 2
Excentricity of its orbit, the mean distance being 100000 -	90804
Longitude for 1784 - -	$3^s\ 14^\circ\ 43'\ 18''$
Greatest equation of the centre -	0 5 27 16

Longitude

Longitude of aſcending node in 1788	$2^s\ 12^\circ\ 47'\ 0''$
Secular motion of the node - -	1 44 35
Greateſt aberration - -	25

See GEORGIUM SIDUS, and *Planetary* NUMBERS.

The planet Ceres, firſt diſcovered by Piazzi, January 6, 1801, and afterwards by Dr. Olbers of Bremen, Jan. 1, 1807, nearly in the place where it was expected to appear from the calculations of baron Zach, is of a ruddy colour, and ſeems to be about the ſize of a ſtar of the eighth magnitude; apparently ſurrounded by a denſe atmoſphere, and plainly exhibiting a diſc, when examined with a magnifying power of about 200. Its revolution round the ſun is performed in four years, ſeven months, and ten days; at a mean diſtance of nearly 260 millions of Engliſh miles. The excentricity of its orbit is ſomewhat greater than that of Mercury, and its inclination to the ecliptic exceeds that of all the old planets. According to Dr. Herſchel, its diameter does not exceed 160 miles, whereas Mr. Schroeter makes it 1624 miles. The following table comprehends all the particulars that are known concerning it.

Tropical revolution, La Lande -	$4^y\ 7^m\ 10^d$
Do. from Maſkelyne's Table, -	$1681^d\ 12^h\ 9'$
Annual motion - - -	$2^s\ 18^\circ\ 14'\ 0''$
Mean longitude, January 1, 1804 -	10 11 59 0
Place of aſcending node, from Maſkelyne's Table, in 1802 -	2 20 58 40
Do. in 1804, according to La Lande	2 21 6 0
Place of aphelion in 1802 -	4 25 57 15
Do. according to La Lande, Jan. 1, 1804	4 4 26 44
Excentricity, the mean diſtance being 1, according to Maſkelyne -	0.08141
Do. according to La Lande -	0.079
Inclination of orbit - -	$10^\circ\ 37'\ 0''$
Greateſt equation of centre, Maſkelyne	9 20 8
——————————, La Lande	9 3 0
Mean diſtance from the Sun, that of the Sun from the Earth being 1, La Lande	- 2.77
Do. from Maſkelyne's Table -	2.735
Mean diſtance in Engliſh miles -	260.000.000
Diameter in Engliſh miles, Herſchel -	163
——————————, Schroeter	1624
Apparent mean diameter, as ſeen from the Earth - -	- $1''$

See CERES, and *Planetary* NUMBERS.

For an account of the planet Pallas, ſee PALLAS, and *Planetary* NUMBERS.

Juno, a planet diſcovered, as we have ſaid under JUNO, in 1804, is of a reddiſh colour, and free from that nebuloſity which ſurrounds Pallas. Its diameter is leſs, and its diſtance greater than thoſe of the other new planets. It is diſtinguiſhed from all the other planets by the great excentricity of its orbit; and the effect of this is ſo extremely ſenſible, that it paſſes over that half of its orbit, which is biſected by its perihelion, in half the time that it employs in deſcribing the other half, which is farther from the ſun. From the ſame cauſe, its greateſt diſtance from the ſun is double the leaſt diſtance, the difference between the two diſtances being about 127 millions of miles. The following elements were calculated by Burckhardt.

Revolution - -	$5^y\ 182^d$
According to others (ſee *Planetary* NUMBERS) in - - - - - -	$1590^d\ 1\ 35'$
Mean longitude, 31ſt December, 1804, noon, - -	$1^s\ 12^\circ\ 17'\ 23''$
Place of aſcending node - -	5 21 6 0
Place of perihelion in 1805 -	1 29 49 33
Excentricity, the mean diſtance being 100.000 - - -	25096
Inclination of orbit - - -	$21^\circ\ 0'\ 0''$
Mean diſtance from the Sun in Engliſh miles - -	275.000.000
Diameter in Engliſh miles, according to Schroeter	1425
Apparent mean diameter, as ſeen from the Earth, according to Schroeter	$3''.057$

See JUNO.

Dr. Olbers, who had diſtinguiſhed himſelf by the diſcovery of two of the new planets, conceived, that theſe ſmall celeſtial bodies were merely the fragments of a larger planet, which had been burſt aſunder by ſome internal convulſion, and that ſeveral more might be diſcovered between the orbits of Mars and Jupiter. He therefore concluded, that though the orbits of all theſe fragments might be differently inclined to the ecliptic, yet, as they muſt have all diverged from the ſame point, they ought to have two common points of reunion, or two nodes in oppoſite regions of the heavens, through which all the planetary fragments muſt ſooner or later paſs. One of theſe nodes Dr. Olbers found to be in Virgo, and the other in the Whale, and it was actually in the latter of theſe regions that Mr. Harding diſcovered the planet Juno. With the intention therefore of detecting other fragments of the ſuppoſed planet, Dr. Olbers examined, thrice every year, all the little ſtars in the oppoſite conſtellations of the Virgin and the Whale, till his labours were crowned with ſucceſs on the 29th of March, 1807, by the diſcovery of a new planet in the conſtellation Virgo, to which he gave the name of Veſta. This planet was obſerved at Blackheath the 26th of April, 1807, by S. Groombridge, eſq., an ingenious and active aſtronomer; and purſuing his obſervations with perſevering attention and induſtry, he at length, *viz.* on the 8th of September, 1808, obſerved the ecliptic oppoſition of this planet at $7^h\ 30'$ in longitude $11^s\ 15^\circ\ 54'\ 26''$.

The planet Veſta is of the fifth or ſixth magnitude, and may be ſeen in a clear evening by the naked eye. Its light is more intenſe, pure, and white than any of the other three. It is not ſurrounded with any nebuloſity, and has no viſible diſc. (Phil. Tranſ. 1807, part ii. p. 265. 260.) The orbit of Veſta cuts the orbit of Pallas, but not in the ſame place where it is cut by that of Ceres. According to the obſervations of Schroeter, the apparent diameter of Veſta is only 0.488 of a ſecond, one half of what he found to be the apparent diameter of the fourth ſatellite of Saturn; and yet it is very remarkable, that its light is ſo intenſe, that Mr. Schroeter ſaw it ſeveral times with his naked eye. Phil. Tranſ. 1807, part ii. p. 245.

M. Burckhardt is of opinion, that Le Monnier had obſerved this planet as a fixed ſtar, ſince a ſmall ſtar, ſituated in the ſame place, and obſerved by that aſtronomer, has ſince diſappeared.

The following are the elements of the orbit of Veſta, computed by Mr. Groombridge, from his own obſervations.

Revolution - - -	$3.^y182$
According to others (ſee *Planetary* NUMBERS) in - - - - -	$1335^d\ 0^h\ 23'$
Place of aphelion - -	$6^s\ 3^\circ\ 0'\ 0''$
Place of aſcending node -	3 14 38 0
Inclination of orbit - -	7 8 20
Mean diſtance - - -	2.163
Excentricity in parts of the Earth's radius	0.0953

The following elements are given by Burckhardt, in the Connoiſſance de Temps for 1809, from the moſt recent obſervations on the continent.

Place

Place of afcending node	$3^s\ 13^\circ\ 1'\ 0''$
Place of perihelion	8 9 42 53
Inclination of orbit	7 8 46
Mean diftance	2.373000
Excentricity	0.093221

We fhall fubjoin to the account above given of the four new planets, called by Dr. Herfchel *afteroids* (which fee), fome obfervations concerning their origin. From a variety of confiderations it has been concluded, agreeably to the opinion fuggefted by Dr. Olbers, that thefe four planets are the fragments of a large celeftial body, which once exifted between Mars and Jupiter. On the fuppofition that they are independent planets, their diminutive fize, the great excentricity and inclination of their orbits, and their numerous interfections, when projected on the plane of the ecliptic, are phenomena abfolutely inexplicable on every principle of fcience, and completely fubverfive of that harmony and order, which, before the difcovery of thefe bodies, pervaded the planetary fyftem. But if we admit the hypothefis, that thefe planets are the remains of a larger body, which circulated round the fun, nearly in the orbit of the greateft fragment, the fyftem refumes its order, and we difcover a regular progreffion in the diftances of the planets, and a general harmony in the form and pofition of their orbits. Thus does the ingenious Dr. Brewfter introduce his general reafoning on this fubject. He then proceeds to obferve, that the elements of the new planets furnifh us with feveral direct arguments, drawn from the excentricity and inclination of their orbits, and from the pofition of their perihelia and nodes, and all concurring to fhew, that the four new planets have diverged from one point of fpace, and have, therefore, been originally combined in a larger body. When the original planet burft in pieces, by fome internal force capable of overcoming the mutual attraction of the fragments, the larger fragment muft obvioufly receive the leaft impetus from the explofive force, and circulate in an orbit deviating lefs than any other of the fragments from the original path of the large planet; while the leffer fragments, being thrown off with greater velocity, would revolve in orbits more excentric, and more inclined to the ecliptic. Applying this remark to the cafe before us, the excentricity of Ceres and Vefta is nearly one-twelfth of their mean diftance, that of Ceres being rather the greateft; and the excentricity of Pallas and Juno is one-fourth of their mean diftance, that of Pallas being a little greater than that of Juno. From the theory it might be expected, that Pallas and Juno would be confiderably fmaller than Ceres and Vefta, and that Ceres fhould be the larger fragment, and have an orbit more analogous in excentricity and inclination than any of the fmaller fragments to the other planets of the fyftem. As far as the diameters of the new planets have been meafured, the theory is very ftrikingly confirmed by obfervation. According to Dr. Herfchel, the diameter of Ceres is 163 miles, while that of Pallas is only 80. The obfervations of Schroeter make Juno confiderably lefs than Ceres; and though the diameter of Vefta has not been accurately afcertained, yet the intenfity of its light, and the circumftance of its being diftinctly vifible to the naked eye, are ftrong proofs that it exceeds in magnitude both Pallas and Juno. The ftriking refemblance between the two leffer fragments, Pallas and Juno, in their magnitudes, and in the extreme excentricity of their orbits, would lead us to anticipate fimilar refemblances in the pofition of their nodes, in the place of their perihelia, and in the inclination of their orbits; while the elements of Ceres and Vefta fhould exhibit fimilar coincidences. Now, the inclination of Ceres is 10°, and that of Vefta 7°; while the inclination of Juno is 21°, and that of Pallas 34°; the two greater fragments having nearly the fame inclination, and keeping near the ecliptic, while the leffer fragments diverge from the original path, and rife to a great height above the ecliptic, and far above the orbits of all the other planets in the fyftem. If it fhall be found, from obfervation, that Vefta is one of the fmaller fragments, we may then account for its pofition with regard to Ceres, and for the fmall inclination and excentricity of its orbit, by fuppofing the planets Ceres, Pallas, and Juno, to have diverged in the fame plane, and nearly at right angles to the ecliptic, while Vefta diverged from the direction of the original planet, in a plane parallel with the ecliptic. This opinion is ftrongly confirmed by the fact, that the orbit of Vefta is nearer to the fun than either of the orbits of the other three fragments. The fame coincidence is apparent in the pofition of the nodes. The orbits of Pallas and Juno cut the ecliptic in the fame point, and the nodes of Ceres and Vefta are not far diftant. If all the fragments of the original planet had, after the explofion, been attracted to the larger fragment, it is obvious that they would all move in the fame orbit, and confequently have the fame perihelion. If the fragments received a flight degree of divergency from the explofive force, and moved in feparate orbits, the points of their perihelion would not coincide, and their feparation would increafe with the divergency of the fragments. But, fince all the fragments partook of the motion of the primitive planet, the angle of divergency could never be very great; and, therefore, we fhould expect that all the perihelia of the new planets would be in the fame quarter of the heavens. This theoretical deduction is moft wonderfully confirmed by obfervation. Thefe fingular refemblances, as our author clofes his reafoning on this fubject, in the motions of the greater fragments, and in thofe of the leffer fragments, and the ftriking coincidences between theory and obfervation in the excentricity of their orbits, in their inclination to the ecliptic, in the pofition of their nodes, and in the places of their perihelia, are phenomena which could not poffibly refult from chance, and which concur to prove, with an evidence amounting almoft to demonftration, that the four new planets have diverged from one common node, and have therefore compofed a fingle planet. Our author proceeds to account for the origin of meteoric ftones, which he confiders as phenomena that might accompany this great convulfion. Fergufon's Aftronomy, by Dr. Brewfter, vol. ii. See BALLS *of Fire*, FALLING *Stones*, and GEORGIUM SIDUS.

Saturn is reprefented by the character ♄. This planet, on account of its great diftance, appears to the eye with a feeble light. It performs its revolution round the fun in about thirty years. See SATURN.

Jupiter, marked ♃, is a bright refulgent ftar, finifhing its courfe round the fun in about twelve years. See JUPITER.

Vefta has no character affigned it. See VESTA.

Juno is reprefented by the character ⚵. See JUNO.

Pallas is exhibited under the character ⚴. See PALLAS.

Ceres is marked by ⚳. See CERES.

Mars, characterized ♂, is a ruddy fiery-coloured planet, finifhing its courfe in about two years. See MARS.

The Earth, marked ⊕, performs its revolution in one year. See EARTH.

Venus, ♀, is the brighteft of all the planets, conftantly attending the fun, and never diftant from him above 48 degrees. It finifhes its courfe in about feven months.

When it goes before the fun, it is called *Phofphorus* and *Lucifer;* and when it follows him, *Hefperus*.

Mercury, ☿, a little bright planet, the fun's conftant companion, from whofe fide it never departs above 28 degrees, and by that means is ufually hid in his fplendour.

 It

It performs its courſe in about three months. See MERCURY.

From theſe definitions, a perſon may eaſily diſtinguiſh all the planets. For, if after ſun-ſet he ſees a planet nearer the eaſt than the weſt, he may conclude it is neither Mercury nor Venus; and may determine whether it is Saturn, Jupiter, or Mars, by the colour and light: by which alſo he may diſtinguiſh between Mercury and Venus.

PLANETS, *Nature of the.* From the ſeveral phaſes and appearances of the planets, they are found to be all like the moon, which we have ſhewn to be like our earth; whence it follows, that the planets are alſo dark, opaque, ſpherical, &c. bodies, like our earth.

This may be ſhewn almoſt to a demonſtration.

The phaſes of Mercury are eaſily diſtinguiſhed to be like thoſe of Venus; but no ſpots have yet been diſcovered, by which we can aſcertain whether it has any rotation. Although Dr. Herſchel affirms, in conſequence of his obſervations of this planet, that it appears equally luminous in every part of its body, and that its diſc is always well defined, without any ſpot or ragged edge, Mr. Schroeter thinks that he has diſcovered not only ſpots, but mountains in Mercury. He meaſured two of theſe mountains, the higheſt of which was 8900 toiſes, or $10\frac{3}{4}$ miles, or more than double the height of Chimboraco in the Andes; and the other was little more than 1000 toiſes high. From the variations in the daily appearance of Mercury's horns, this aſtronomer infers that the period of its daily rotation was $24^h\ 5'\ 28''$. Theſe obſervations remain to be confirmed.

Venus, obſerved with a teleſcope, is rarely found full, but with variable phaſes like thoſe of the moon; her illuminated part ſtill turned towards the ſun, *viz.* towards the eaſt when ſhe is the morning-ſtar, and towards the weſt when the evening-ſtar.
